TO THE

GARDENERS, BOTANISTS, AND FLORISTS,

OF

GREAT BRITAIN AND IRELAND,

THE FOLLOWING WORK,

THE RESULT OF MANY YEARS LABOUR AND EXPERIENCE,

IN VARIOUS PARTS OF THESE KINGDOMS,

IS HUMBLY INSCRIBED,

BY THEIR MUCH OBLIGED

AND OBEDIENT SERVANTS,

THE AUTHORS.

# ADVERTISEMENT.

THE kind reception which the authors of this Dictionary have experienced in a book of theirs publiſhed ſome years ago, entitled *Every Man his own Gardener*, of which many thouſands have been ſold, encourages them to hope for the public favour and approbation in a work of a more extenſive nature, but, at the ſame time perfectly conſiſtent with their former labours.

Gardening and Botany are ſo nearly allied, that every profeſſor of Horticulture ought to be a Botaniſt, or at leaſt know the rudiments or principal out-lines of *Botanic Philoſophy*, in conjunction with that of practical Gardening; for, as his province is the propagation and culture of plants, it is neceſſary for him alſo to know the claſs, order, and genus to which every plant under his care belongs, agreeable to their botanic characters and ſyſtematical arrangement.

It will be readily allowed, that ſeveral books of Gardening, from which general inſtruction was expected, have proved deficient, not only in the moſt eſſential parts of Practical Gardening, but alſo in the Botanic Syſtem; from hence it naturally follows, that many practitioners ſtill remain ignorant of the principal branches and operations of Gardening; and the practice of Botany.—On due conſideration of the defective ſtate of the different voluminous books of Gardening, heretofore publiſhed, reſpecting their irregular and unintelligible

arrangements,

arrangements, and the impracticable and prolix directions, for performing the neceſſary operations; we humbly conceived, that a ſyſtem of Univerſal *Gardening and Botany* united, would be highly acceptable, not only to practitioners, but to all others who delight in thoſe laudable purſuits.

We have, therefore, from the reſult of many years extenſive practice and experience in different parts of theſe kingdoms, diligently compoſed a comprehenſive Syſtem of *Univerſal Gardening and Botany*, compriſed in a moderate volume, on an original plan; comprehending, in botanical arrangement, according to the celebrated Linnæan ſyſtem, all the known trees, ſhrubs, and herbaceous plants, natives and exotics, that are cultivated, or merit general culture either for uſe, ornament, curioſity, or obſervation; with the names of the claſſes, orders, genera, and of the different ſpecies of plants in each genus or family; together with the deſcription of their general habit and ſtructure, and all the proper botanic terms of art uſed in diſcriminating the various parts of plants.

We have alſo explained the different temperatures of the various trees and plants, hardy and tender, whether for the full ground or the green-houſe, ſtove or hot-bed, &c. and deſcribed the ſeveral uſes of the various plants in gardening and for œconomical purpoſes; their proper arrangement in every department, both in the various hardy plantations, as the Nurſery, Pleaſure-ground, Flower-garden, Kitchen-garden, Fruit-garden, Woods, and Foreſts; and in the Green-houſe, Stove, Hot-beds, Frames, &c. With the practical method of raiſing or propagating every different tree and plant; and their general method of culture, in every ſtage of growth, in the ſeveral diſtricts of Gardening.

The reader will find full directions, from experience, for managing the Nurſery, Pleaſure-ground, Shrubbery, Flower-garden, Kitchen-garden, Fruit-garden, Timber-plantations, Green-houſe, Stove, Hot-beds, Forcing-frames, Common-frames, &c. and alſo directions for performing the mechancial operations of the different methods of ſowing and planting all ſorts of ſeeds, roots, and

plants,

plants, in every department of Gardening and Planting. Alſo the operations of propagating the numerous ſpecies of trees, ſhrubs, and herbaceous plants, either by ſeed, ſuckers, ſlips, off-ſets, parting roots, layers, cuttings, grafting, budding, inarching, &c. Together with the beſt method of performing all other mechanical operations of Gardening; and a deſcription of the proper ſoils, manures, ſituations, and expoſures for the various garden diſricts, and reſpective plants.

Some apology may be neceſſary for the ſtyle; but when it is conſidered, that perſpicuity ought to be preferred to elegance, the good-natured reader will pardon little miſtakes in language, if the meaning is clear and obvious.

THE

# UNIVERSAL GARDENER

AND

# BOTANIST.

ACANTHUS, formerly named *Branca Urſina*, i. e. Bears-breech.

This genus retains five diſtinct ſpecies, four of which are hardy herbaceous perennials of the flowery tribe, that obtain three or four feet ſtature, adorned at top with numerous flowers in erect ſpikes, and merit eſteem as plants of ornament for the embelliſhment of the pleaſure ground. The other is an evergreen ſhrub, of the temperature of ſtove exotics.

The *Acanthus* belongs to the claſs and order *Didynamia Angioſpermia*, and its characters are,

The CALIX, three pair of leaves forming a kind of triple cup. The COROLLA, monopetalous and ringent, opening above with a mouth, hath a broad under lip, but the upper one is wanting. The STAMINA, are two ſhort and two long filaments, having compreſſed antheræ. The PISTILLUM, a turbinated germen ſupporting a filiforme ſtyle, terminated by two acute ſtigma. PERICARPIUM, a roundiſh capſule of two cells, pregnant with ſmooth fleſhy ſeeds.

The ſpecies are,

[1] ACANTHUS *Mollis.*

*Smooth Acanthus.*] Acanthus with deeply ſinuated and indented, ſmooth, unarmed leaves.

[2] ACANTHUS *Spinoſus.*

*Thorny Acanthus.*] Acanthus with deeply jagged many-pointed leaves, having each ſegment terminated by a thorny point.

[3] ACANTHUS *Niger.*

*Shining leaved Acanthus.*] Acanthus with ſinuated, unarmed, ſmooth, ſhining leaves.

[4] ACANTHUS *Dioſcoridis.*

*Acanthus of Dioſcorides.*] Acanthus with ſpear-ſhaped entire leaves, having ſpinous borders.

[5] ACANTHUS *Ilicifolio.*

*Holly leaved ſhrubby Acanthus.*] Acanthus with a ſhrubby ſtalk, and waved, dentated, ſpinous edged leaves.

The firſt four ſpecies are hardy, herbaceous, fibrous-rooted plants, that produce ſtalks annually, three or four feet high, perennial in root, but annual in leaf and ſtalk, they riſing in ſpring, and periſh in autumn.

The roots are compoſed of thick fleſhy fibres, which are conſiderably ſpreading, and penetrate deep in the earth.

The leaves and flower-ſtalks riſe immediately from the root. The leaves ſpread near the ground; they are large and long, generally from about ten or twelve to eighteen inches in length, and half as much in breadth. Thoſe of the firſt, ſecond, and third ſorts are variouſly ſinuated, divided, and indented, and ſpreading in circular cluſters, and form a ſingularly elegant appearance. The flower-

ſtalk riſes between the leaves, and attains three or four feet ſtature, erect, round, thick, fleſhy, and decorated upward with numerous flowers. The flowers are univerſally hermaphrodite, and formed each of one tubular petal, the colour chiefly white, and arrange themſelves in a thick ſpike along the upper part of the ſtalk, each ſeparate flower occupying a diſtinct cup. They appear in July and Auguſt, continue a month or ſix weeks, and are ſucceeded by plenty of ripe ſeed in autumn.

The *Acanthus Mollis* was greatly celebrated in ancient times for the elegance of its leaf, which attaining a conſiderable length and breadth, and having its edges curiouſly ſcalloped, undulated, and indented in a ſingularly beautiful manner, is the chief ornament of the plant.

The *Acanthus Spinoſus* is alſo a noble plant, and demands our attention for the ſingularity of its large many pointed thorny leaves, which form a pleaſing variety.

The above two ſpecies are the moſt commonly known and cultivated in the Engliſh gardens.

Theſe plants are natives of Italy, Spain, and Portugal, but grow freely here in the full ground, and are of eaſy culture.

The *Acanthus Ilicifolio* is a low evergreen ſhrub, a native of South America, and requires the aid of a ſtove to retain it in this country.

*Uſe in Gardens, Propagation, &c.*

With reſpect to the merit of theſe plants in gardens; the herbaceous ſpecies may with propriety be employed as furniture for the decoration of common large borders, and other ſimilar compartments of the pleaſure ground, and they may be introduced in the ſhrubbery clumps, toward the front, between ſhrubs of moderate growth. Their flowers, though not elegant, are conſpicuous; which, together with the pleaſing ſingularity of the leaves, the plants will effect the purpoſe both of variety and ornament.

They proſper in any common ſoil, and do not require any particular expoſure.

The four herbaceous ſpecies may be propagated both by ſeed and by parting the roots.

The ſeed grows freely in the common ground, and ſhould be ſown in March or April, either in ſhallow drills, or on the ſurface, and raked in, or covered with earth half an inch deep. The plants will appear in ſix weeks, thin them to ſix inches, and in autumn or ſpring following tranſplant them into the borders, where they will flower the ſucceeding ſummer.

The propagation by parting the roots may be effected in autumn or ſpring: the ſmalleſt off-ſet will readily grow; it however is not eligible to part them too ſmall. See PARTING-ROOTS. Plant them at once where they are to continue.

Their general culture is only to allow ſupport, when neceſſary, to the flower ſtalks, and when theſe decay in autumn, to cut them down.

Theſe plants are retained in moſt of the nurſeries for ſale, particularly the Smooth and Thorny Acanthus.

ACAULES *Plants*, i. e. without a caulis, or ſtem. A term uſed by botaniſts expreſſive of plants that have no viſible ſtalk, but grow cloſe to the ground.

ACER, The Maple Tree.

This genus furniſhes a large collection of hardy deciduous trees, being ſuch as caſt their leaves in autumn, and remain diveſted of them during the winter; they claim attention, ſome as timber trees, others for uſeful and ornamental purpoſes in gardening.

The *Acer* belongs to the claſs and order *Polygamia Monoecia*, and its characters are,

The CALIX, monophyllous, five-parted, coloured, and permanent. COROLLA, five oval expanded petals. STAMINA, eight filaments with ſimple antheræ. PISTILLUM, a compreſſed germen and ſlender ſtyle, having two acuminated ſtigma. PERICARPIUM, two roundiſh, united, winged capſules, each containing one ſeed.

The ſpecies and reſpective varieties are,

[1] ACER *Campeſtre.*

*Common or Smaller Maple.*] Maple with lobated and obtuſely emarginated leaves.

[2] ACER *Pſeudo-Platanus.*

*Falſe Platanus, Greater Maple, or Sycamore-Tree.*] Maple with leaves divided into five lobes, having the edges unequally ferrated, and flowers produced in a racemus.

*Variety.*] Sycamore-tree with variegated leaves.

[3] ACER *Rubrum.*

*Scarlet-flowering Maple.*] Maple with leaves divided into five ſlightly indented lobes, white on the under ſide, and with aggregate flowers.

*Variety.*] Wager's flowering maple, with the largeſt aggregate of flowers.

[4] ACER *Saccharinum.*

*Sugar*

*Sugar Maple.*] Maple with five-parted palmated leaves, having the edges ſharply indented.

[5]ACER *Platanoides.*

*Platanus-leaved Norway Maple.*] Maple with ſmooth ſhining leaves, divided into five ſharp-pointed and acutely indented lobes, and flowers produced in a corymbus.

*Variety.*] Norway maple with variegated leaves.

[6]ACER *Penſylvanicum.*

*Penſylvanian Mountain Maple.*] Maple with leaves having three acuminated and ſharply ſerrated lobes, and flowers produced in a racemus.

[7]ACER *Negundo.*

*Aſh-leaved Virginia Maple.*] Maple with leaves compoſed of ſeveral diſtinct lobes, and with flowers produced in a racemus.

[8]ACER *Monſpeſſulanum.*

*Montpelier or French Maple.*] Maple with ſhining leaves, having three lobes with entire edges.

[9]ACER *Opalus.*

*The Opalus or Italian Maple.*] Maple with large roundiſh lobated, ſlightly cut leaves, and flowers produced in a racemus.

[10]ACER *Creticum.*

*Cretan or Levant Maple.*] Maple with leaves divided into three lobes, having the edges entire, and the under ſide a little downy.

[11]ACER *Tartaricum.*

*Tartarian Maple.*] Maple with oblong heart-ſhaped, ſlightly lobated, and unequally ſerrated leaves.

All the above ſpecies and reſpective varieties are of the tree kind, deciduous, and of hardy temperature, that proſper in almoſt any ſoil and expoſure, in common with other hardy deciduous trees.

Moſt of the ſpecies, except the *Acer Campeſtre* and *Pſeudo-platanus*, are natives originally of diſtant climates, ſome of America, and others of different parts of the continent of Europe, and the countries annexed to their names; but moſt of the ſorts are now cultivated in the Engliſh nurſeries, for the ſupply of noblemen and gentlemen's plantations.

Theſe trees are of ſtature from about twenty to forty feet or upward, the Greater Maple frequently exceed that height, and the Norway, Aſh-leaved, Sugar, and Italian Maple are likely to attain that height at leaſt in this country; but the other ſpecies rarely obtain more than twenty or thirty feet ſtature. Moſt of the ſpecies branch out irregularly at firſt, but in time form pretty full and regular heads, ornamented chiefly with oppoſite leaves. The leaves are univerſally ſimple, except the *Acer Negundo*, and are from about three to ſix or eight inches broad, and generally divided into three or five lobes, ſome but ſlightly, others deeply divided; and ſome have the edges of the lobes entire, others indented, and ſome are ſerrated or ſawed, by which diſtinction the different ſpecies may with facility be detected. The flowers ariſe chiefly from the ſides of the young branches, and are produced in a racemus, and ſome in a corymbus, &c. appearing in ſpring and early in ſummer, and are ſucceeded by ripe ſeed the beginning of autumn.

Moſt of the ſorts ripen ſeed perfectly in England, which is remarkably free of growth, as is evident by that which ſcatters promiſcuouſly from the trees, from which many young plants often riſe naturally, particularly the Common and Greater Maples.

The *Common Maple* grows wild in woods and hedges. This tree attains but a moderate ſtature, and its foliage is ſmall: it is ſometimes admitted for variety in extenſive plantations.

The *Greater Maple* is a ſtately tree, of free growth, decorated with luxuriant foliage, that afford a delightful ſhade, and both the plain and variegated ſort effect an agreeable diverſity in ornamental plantations.

The *Acer Rubrum* is a tree of moderate growth, the leaves are large, and the flowers have great beauty, particularly thoſe of the ſecond variety, i. e. Sir Charles Wager's Flowering Maple, which ariſe in numerous large cluſtering heads, and are extremely conſpicuous and ornamental.

The *Acer Saccharinum*, *Platanoides*, and *Aſh-leaved Maples*, are all three large growing trees, and are proper to be employed in outward plantations; as their leaves are of different ſizes and ſhapes, and of lighter and darker ſhades, they afford a pleaſing variety: if ſome trees are diſperſed in parks and other extenſive places, they will diverſify the general ſcene; the corymbus flowers of the *Acer Platanoides* have ſingular beauty; and the ſort with variegated leaves forms a pretty diverſity.

The firſt of the above three trees, i. e. *Sugar Maple*, obtained the name from the circumſtance of its imparting a great quantity of

ſweet juice, with which a tolerable good ſugar is prepared. This juice is obtained by piercing or tapping the trees, and from which parts the juice continue to iſſue for ſeveral days. This is greatly practiſed in America, where the trees are large and numerous. The property of the ſweet juice is not however limitted to this particular ſpecies, for even the Greater Maple, and ſome other large kinds, are found to emit great quantities, little inferior to that of the ſpecies under conſideration.

The *Penſylvanian* and *Montpelier Maples* are trees of moderate growth, and the leaves are of a middle ſize; thoſe of the latter are of a thick conſiſtence, have a ſhining ſurface, and continue late in autumn, which render them of eſteem for ornamental purpoſes.

The *Acer Opalus* is a noble tree; it acquires a conſiderable ſtature, hath a ſpreading head, adorned with large and beautiful foliage.

The *Cretan* and *Tartarian Maple* are trees of humble ſtature, and are very proper for interior plantations.

*Uſes in Gardening, Propagation, &c.*

For purpoſes in gardening, moſt of the ſpecies are proper to be employed in ornamental plantations and parks, and other extenſive departments, in aſſemblage with other hardy deciduous trees of ſimilar growth; in forming detached clumps, groves, thickets, avenues, ſhade for ſpacious walks and rural ſeats; and in forming running or continued plantations on the boundaries of extenſive lawns, parks, &c.

All the ſorts may be propagated with great facility by ſeed, and moſt of them may likewiſe be encreaſed by layers and cuttings.

The ſeed grows freely in the common ground, and the time of year for ſowing it is autumn, ſoon after it is ripe, or early in ſpring; but the former is generally the moſt ſucceſsful ſeaſon, as that of the ſpring ſowing is apt to riſe ſtraggling. Chooſe a light mellow ſpot, and after being dug, divide it into one or more beds, three or four feet wide; ſmooth the ſurface and ſow the ſeeds thereon, and cover them a little more than half an inch deep. The plants will appear in April or May, and by Michaelmas they will be eight or ten inches high; when, or in the enſuing ſpring, ſome of the largeſt may be tranſplanted, and in autumn following the whole; planting them in the nurſery in rows two feet and half diſtance.

They ſhould be permitted to have at leaſt four or five years growth in the above nurſery, or till they have attained five or ſix feet ſtature, when they may be employed in plantations.

The propagation by layers and cuttings may be performed in autumn; chooſe the ſhoots of the young branches, and in one year they will be well rooted. See LAYERS and CUTTINGS.

The variegated kinds are encreaſed either by layers, cuttings, or inoculation, though ſometimes the ſycamore comes variegated from the ſeed of the ſame kind; but the moſt certain means of obtaining them is by the above methods, when every plant ſo raiſed will have the ſame variegations as the parent tree.

All the varieties of theſe trees are propagated for ſale in moſt of the nurſery gardens.

ACETOSA, Sorrel. See RUMEX.

ACHILLEA, Milfoil, Yarrow, and Sneezwort.

The plants of this genus are herbaceous fibrous rooted perennials, of hardy growth; ſome merit eſteem for medical purpoſes, and ſome as plants of ornament.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] The FLOWER is compound and radiated. CALIX, the common cup is oval and imbricated. COROLLA, ſeveral tubular hermaphrodite florets compoſe the diſk, and five flat female florets the radius. STAMINA, five capillary filaments in each hermaphrodite floret. PISTILLUM, a ſmall germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM none, the ſeeds being lodged in the calix.

There are twenty ſpecies, thoſe that demand attention are,

[1]ACHILLEA *Millefolium.*

*Common Milfoil or Yarrow.*] Achillea with doubly pinnated leaves, the lobes cut into many narrow ſegments and white umbels.

*Variety.*] Common Milfoil with purple umbels.

[2]ACHILLEA *Ptarmica.*

*Ptarmica or Common Sneezwort.*] Achillea with ſpear-ſhaped pointed leaves, having the edges ſharply ſerrated, and white umbels.

*Variety.*] Ptarmica with double flowers.

[3]ACHILLEA *Ageratum.*

*Ageratum or Sweet Maudlin.*] Achillea with ſpear-ſhaped obtuſe leaves, with the edges acutely ſawed, and yellow umbels.

*Variety.*] Long-corymbus flowered ſweet Maudlin.

[4]ACHILLEA

[4]ACHILLEA *Tomentoſa.*

*Hoary, bright, yellow Milfoil.*] Achillea with pinnated, rough, hoary leaves; the lobes very narrow and indented, and bright yellow umbels.

[5]ACHILLEA *Clavenna.*

*Pinnatifid hoary Alpine Sneezwort.*] Achillea with pinnatifid, plain, obtuſe, hoary leaves, and flat white umbels.

[6]ACHILLEA *Nana.*

*Dwarf hoary Alpine Milfoil.*] Achillea with pinnated and indented downy leaves, and globular white umbels.

[7]ACHILLEA *Ægyptiaca.*

*Ægyptian hoary Sneezwort.*] Achillea with pinnated hoary leaves, the lobes obtuſely ſpear-ſhaped, ſawed, and indented, and yellow umbels.

[8]ACHILLEA *Abrotanifolio.*

*Southernwood-leaved Milfoil.*] Achillea with pinnated, ſupra-decompound, hoary leaves; the ſegments very narrow, and ſtand remote, and yellow umbels.

[9]ACHILLEA *Macrophylla.*

*Long fever-few-leaved Sneezwort.*] Achillea with pinnated, deeply ſerrated, plane leaves; the outermoſt wings the largeſt, and looſe white umbels.

[10]ACHILLEA *Pubeſcens.*

*Downy Tanſey-leaved Sneezwort.*] Achillea with pinnated downy hoary leaves, the lobes ſpear-ſhaped, deeply cut and ſerrated, and pale yellow umbels.

[11]ACHILLEA *Nobilis.*

*Noble or Sweet Milfoil.*] Achillea with doubly pinnated, finely divided, ſweet ſcented leaves, the lower ones plane and naked, the upper obtuſe and downy, and a convex white umbel.

*Variety.*] Noble Milfoil with pale red umbels.

[12]ACHILLEA *Santolina.*

*Lavender-cotton-leaved Eaſtern Sneezwort.*] Achillea with indented briſtly hoary leaves, the denticles almoſt entire, awl-ſhaped and reflexed, and large yellow umbels.

Of the above ſpecies, the *Purple Milfoil*, *Double Ptarmica*, and *Achillea Tomentoſa* are the moſt commonly known and cultivated.

All the ſpecies are hardy herbaceous perennials, that proſper in any common ſoil, and obtain from ſix inches to three feet ſtature, ſurmounted by flowery umbels.

The roots are fibrous, which in many ſpecies creep in a horizontal direction, and multiply exceedingly.

The leaves and flower-ſtalks riſe from the root annually. The ſtalks attain different heights, from half a foot to a yard or upward, decorated with leaves, and terminated by the umbels of flowers. The leaves in ſome are ſimple, but in the greater part winged or pinnated, and divided into a multitude of minute ſegments, in the manner of tanſey, wormwood, chamomile, &c. which in moſt ſpecies poſſeſs different degrees of hoarineſs, and have an ornamental effect in a garden.

The flowers ſingly are ſmall, but numerous, many being produced together from the ſummit of the ſtalks, in a ſort of umbel or rather corymbus, appearing in June, July, Auguſt, and September, and are ſucceeded by ripe ſeed in autumn.

The two firſt ſpecies grow naturally in England, all the others were obtained from diſtant parts, as the Alps, France, Spain, Italy, and the Archipelago, &c.

The *Achillea Millefolium* and *Ptarmica* attain two or three feet ſtature. The common ſpecies grow wild in paſtures, woods, and ſides of banks. They are eſteemed for medical uſes; and the two varieties, *Purple Milfoil* and *Double Sneezwort* are admitted in gardens as ornamental plants. The roots of the *Common Sneezwort* are remarkable for provoking ſneezing; and being acrid, a bit chewed in the mouth, often procures a temporary reſpite in the tooth-ach.

The *Sweet Maudlin* riſes two feet high, the leaves impart a fragrant odour. The common ſpecies is cultivated for medicine, and the variety is retained as a flowering plant.

The *Achillea Tomentoſa*, *Clavennæ*, *Nana*, and *Ægyptiaca*, are of humble growth, ſeldom obtaining more than from ſix to twelve inches height, have very hoary leaves, and adorned with moderately large, compact, and very ornamental umbels.

The other five ſpecies grow from eighteen inches to a yard high, the leaves chiefly hoary, and the umbels large.

*Uſe in Gardens, Propagation, &c.*

For purpoſes in gardens, the ſingularity of the hoary leaves of many ſorts form a pretty variety, and the flowers being conſpicuous, and continue two or three months, render the plants proper furniture for common borders, and the fronts of ſhrubbery compartments.

All the ſorts may be readily propagated by parting the roots any time in autumn or ſpring, and ſome alſo by ſlips and cuttings of the

the ſtalks, &c. in a ſhady border in ſummer.

Many of the ſorts furniſh plenty of ſeed, by which they may likewiſe be raiſed by ſowing them in March or April, in a bed of light earth, and the plants will be fit to tranſplant for good at Michaelmas, and will flower the following ſummer.

ACHRAS, Sapota-Tree, or Mammee Sapota.

This genus retains but two ſpecies, which are of the tree kind, natives of the warm parts of America; their merit here is merely for variety, and require the conſtant aid of a ſtove.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, ſix acute permanent leaves. COROLLA, five heart-ſhaped petals joined at the baſe. STAMINA, ſix ſhort filaments, having arrow-pointed antheræ. PISTILLUM, an oval germen, a ſhort ſtyle, and blunt ſtigma. PERICARPIUM is of the apple kind, containing one or two oval hard nuts.

The ſpecies are,

[1]ACHRAS *Sapota.*

*Common Sapota-Tree* ] Achras with oblong oval leaves, and ſmooth top-ſhaped fruit.

[2]ACHRAS *Mamoſa.*

*The Mammee Sapota of the Weſt Indies.*] Achras with ſpear-ſhaped leaves, large oval fruit, both ends terminating in a ſharp point.

Theſe trees in America riſe thirty feet high, but thoſe cultivated here in our ſtoves appear as ſhrubs; the leaves are large, thoſe of the ſecond ſort approach near a foot in length, the flowers are of a cream colour, and are ſucceeded by a kind of apple, conſiſting of thick ſucculent pulp, of a luſcious taſte.

Both the ſpecies are propagated here by ſeed, i. e. the nuts or ſtones included in the fruit, which muſt be procured from the Weſt Indies, and as ſoon as they arrive, planted in pots, and plunged in a hot-bed under frame and glaſs, or in the bark bed in the ſtove.

Their culture is the ſame as other woody exotics, of ſimilar temperature. See STOVE PLANTS.

ACHYRANTHES.

The plants are chiefly herbaceous, and ſomewhat ſhrubby perennials, exotics, of the temperature of green-houſe and ſtove plants, retained more for variety than beauty.

Claſs and order, *Pentandria Monogynia.*

*Character.*] CALIX, five acute ſtiff permanent leaves. COROLLA, none. STAMINA, five filaments with ſmall antheræ. PISTILLUM, a ſingle ſtyle having a bifid ſtigma. PERICARPIUM none; one roundiſh ſeed lodged in the calix.

There are eight or nine ſpecies, but poſſeſſing little merit, there is but one ſort commonly known among gardeners, which is,

ACHYRANTHES *Aſpera.*

*Common Sicilian and American Achyranthes.*] Achyranthes with erect ſtalk, ob longpointed leaves, and adpreſſed ſpikes of flowers, having reflexed cups.

The plant riſes a yard high, decorated with oblong leaves, and long ſpikes of apetalous flowers, which proceed from the ends of the branches, appearing in July and Auguſt, and ripen ſeeds in September.

This plant ſhould be potted and kept in the ſtove, or good green-houſe, in winter.

The propagation of this plant may be effected by ſeed and by cuttings, aſſiſted by a hot-bed.

The following are ſome of the other ſpecies of leſs note.

[1]ACHYRANTHES *Lanata.*] Woolly cupped African Achyranthes, with whorled ſpikes.

[2]ACHYRANTHES *Indica.*] Indian Achyranthes, with oval waved leaves and reflexed flowers.

[3]ACHYRANTHES *Sanguinolenta.*] Bloody leaved Achyranthes.

[4]ACHYRANTHES *Lappacea.*] Climbing lappaceous fruited Achyranthes.

[5]ACHYRANTHES *Muricata.*] Shrubby prickly cupped Achyranthes, with alternate leaves.

Theſe are chiefly of the tribe and temperature of the common ſpecies.

ACONITUM, Aconite, Monk's-hood, or Wolf's-bane.

This genus furniſhes ſeveral ſpecies of hardy herbaceous perennials, eſteemed as ornamental garden plants, obtaining in ſtature from two to ſix feet, their ſtems terminated by elegant ſpikes of flowers.

Moſt of the plants of this genus poſſeſs a poiſonous quality.

Claſs and order, *Polyandria Trigynia.*

*Characters.*] CALIX, none. COROLLA, compoſed of five irregular petals, one placed above, one below, and two ſideways, the upper one formed like a hood, and covers the other parts; and in the bottom are two nectariums. STAMINA, numerous filaments, having erect antheræ. PISTILLUM, three or five germina, as many ſtyles, ſurmounted by reflexed ſtigma. PERICARPIUM, three or five

ſive oblong capſules, of one cell, filled with angular ſeeds.

The ſpecies of moſt note are,

[1]ACONITUM *Pyramidale.*

*Common Pyramidal blue Aconite.*] Aconite with leaves divided into many narrow ſegments, and very long pyramidal ſpikes of blue flowers.

[2]ACONITUM *Lycoctonum.*

*Poiſonous yellow Aconite.*] Aconite with palmated, finely divided, hairy leaves, and yellow ſpikes of flowers.

*Variety.*] Large poiſonous yellow Aconite, with palmated ſmooth leaves.

[3]ACONITUM *Anthora.*

*Salutiferous or Wholeſome yellow Aconite.*] Aconite with leaves divided into many long narrow ſegments, and ſulphur-coloured ſpikes.

[4]ACONITUM *Napellus.*

*Napellus or Large blue Aconite.*] Aconite with leaves cut into many linear ſegments, the upper ones broadeſt and marked with a line, and large blue flowers.

*Varieties.*] Roſe-coloured Napellus.—White-flowered Napellus.—Variegated blue and white Napellus.

[5]ACONITUM *Pyrenaicum.*

*Pyrenæan ſquamous leaved yellow Aconite.*] Aconite with leaves divided into long ſegments, theſe deeply jagged into many narrow parts, and lie over one another like ſcales, and pale yellow ſpikes.

[6]ACONITUM *Cammarum.*

*Wedge-lobed Aconite.*] Aconite with leaves divided into many wedge-ſhaped lobes, theſe cut into many acute parts, and large violet-coloured flowers.

*Varieties.*] Wedge-lobed purple Aconite.—Wedge-lobed blueiſh purple Aconite.—Wedge-lobed deep blue Aconite.

[7]ACONITUM *Orientale.*

*Eaſtern tall white Aconite.*] Aconite with palmated leaves, and large white flowers.

[8]ACONITUM *Variegatum.*

*Variegating dwarf blue Aconite.*] Aconite with many parted leaves, the ſegments half cut through, the upper ones the broadeſt, and ſmall ſpikes of variegating blue flowers.

The above eight ſpecies and reſpective varieties are all of the herbaceous tribe, and have perennial roots, but the leaves and ſtems are renewed annually in the ſpring, and periſh in autumn.

The roots of the common ſorts are thick fleſhy tubers, and thoſe of all the ſpecies ſend forth many fibres, and multiply greatly.

The ſtems or flower ſtalks riſe annually from the root, which in different ſpecies attain different heights, from two to ſix feet, erect, round, firm, and cloſely ornamented with leaves below, and numerous flowers upward, arranged in a beautiful erect ſpike, from one to two feet long. The leaves are large and univerſally ſimple, but deeply divided in the palmated manner into many long ſegments; and in ſome, theſe again are variouſly jagged, lacinated, or ſubdivided into many narrow parts in different arrangements, that in the whole the leaves form a ſingularly pretty variety.

The flowers ariſe along the upper part of the main ſtem, ſurrounding it in great numbers, and as the top advances in height, it furniſhes a daily ſucceſſion ſix or eight weeks, and all the ſorts afford plenty of ſeed in autumn.

The ſeaſon of flowering is from the middle of May until September; the *Aconitum Pyramidale* is the firſt in bloom.

*Uſe in Gardens, Propagation, &c.*

Conſidered as ornamental plants, they make a tolerable appearance; their flowers continue long, which, together with the diverſity of their leaves, afford a ſource of variety to the curious. They are adapted for large borders, and may be introduced in vacant ſpaces in ſhrubbery clumps, the compartments on the boundaries of lawns, or thoſe contiguous to ſhady walks, &c. as they will ſucceed between and under trees where the ſhade is not conſiderable, particularly the common blue ſorts.

Great caution ought however to be uſed in admitting them in parts of a garden where children frequent.

With reſpect to the bad quality of theſe plants; they, taken inwardly, prove a deadly poiſon, and the effluvia of the flowers communicate their noxious quality in ſome degree. It is remarkable that the blue Aconites are much more virulent than the yellow kinds. The root of the *Aconitum Anthora* is accounted an antidote to the poiſon of all the other ſpecies, and is the ſort that is uſed in medicine. It is however affirmed, that if this ſort grow near any of the others, it attracts their baneful property, and becomes like them poiſonous.

Of the bad qualities of theſe plants, many avail themſelves to get rid of vermin. A decoction of the roots deſtroy bugs; the ſame part powdered and adminiſtered in bread, or

any

any other palatable vehicle, to rats and mice ſoon proves mortal.

All the ſpecies, &c. are eaſily propagated by ſeed, alſo by parting the roots, which, of the common ſorts, every bit having an eye or bud, will readily grow.

The ſeed grows freely in a bed or border of common earth, and may be ſown early in ſpring, or rather in autumn, ſoon after it is ripe, and in April or May following the plants will appear; give occaſional weeding and watering until the beginning of Auguſt, then prick them three or four inches diſtant in a ſhady border, and in autumn or ſpring after tranſplant them where they are finally to remain.

The propagation by dividing the roots may be effected any time from October till March.

The chief culture they require is to have their decayed ſtalks cut down in autumn.

The plants are natives chiefly of the Alps, Pyrenæan, Helvetian, and other mountainous parts of the continent. The common blue ſorts have been long inhabitants of almoſt every garden, and all the others may be had at the nurſeries.

ACORN, a kind of nut, and is the fruit of all the ſorts of oak, evergreen-oak, and cork-trees. See QUERCUS.

ACORUS, Sweet Ruſh, or *Calamus Aromaticus*.

There is but one known ſpecies, which is a hardy herbaceous perennial of the flag kind, and grows wild, but having a fragrant aromatic odour, is admitted in gardens.

The claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX none. COROLLA, ſix concave petals, and the flowers arranged in a ſort of amentum. STAMINA, ſix filaments, having double antheræ. PISTILLUM, a riſing germen, no ſtyle, but a ſmall prominent ſtigma. PERICARPIUM, a ſhort triangular capſule, containing oval ſeeds.

The ſpecies is,

ACORUS *Calamus*.

*Calamus Aromaticus, or Sweet Ruſh.*]

The plant is a ſort of aquatic, growing naturally in ditches and watery places.

It hath thick jointed roots, long narrow leaves, and flowers produced in a ſort of amentaceous ſpike, ſupported upon a kind of leaf-like ſtalk, appearing in June and July.

The plant grows wild in many parts of the kingdom, and the roots may be tranſplanted in autumn into any moiſt ſoil of a garden, but unleſs the roots are in water they rarely flower.

The nurſery gardeners cultivate the plant for ſale.

ACTÆA, Herb-Chriſtopher, or Bane-Berries.

The plants are herbaceous perennials, of hardy temperature, and tall growth, and eſteemed as plants of ornament, being adorned with curiouſly branched leaves, and numerous ſnow-white flowers, in large ſpikes.

Claſs and order, *Polyandria Monogynia*.

*Characters.*] CALIX, four concave blunt deciduous leaves. COROLLA, four large obtuſe petals. STAMINA, many filaments, having erect double antheræ. PISTILLUM, an oval germen, no ſtyle, the germen crowned by a depreſſed ſtigma. PERICARPIUM, one oval globular berry, of one cell, containing four ſeeds.

There are five or ſix ſpecies, thoſe that claim attention are,

[1]ACTÆA *Spicata*.

*Common ramoſe ſpiked Herb-Chriſtopher*, with black berries.

[2]ACTÆA *Alba*.

*White berried American Herb-Chriſtopher.*] Actæa with a tuberous root, compact oval ſpike, and white berries.

[3]ACTÆA *Racemoſa*.

*Cluſtered long ſpiked American Herb-Chriſtopher.*] Actæa with talleſt ſtalks, and very long reflexed ſpikes.

The firſt ſort grow naturally in woods in many parts of England, the others were obtained from North America.

The plants are perennial in root, but the leaves and ſtems riſe annually in ſpring, attain three or four feet ſtature, flower in ſummer, and decay in autumn.

The roots are compoſed of thick fibres, thoſe of the ſecond are tuberous and knobbed.

The ſtems or flower ſtalks of the firſt and ſecond ſorts riſe two feet and half high, that of the third often four or five; they grow erect, and are adorned below with leaves, and the upper part with numerous flowers, arranged in very ornamental ſpikes terminating the ſtalks. The leaves are both radical and elevated on the ſtalks, they are compound, branched, very long, and compoſed each of twenty-ſeven lobes or folioles, the common foot-ſtalk of each leaf branching or dividing by threes into nine ſmaller, each of which ſuſtain three lobes, and in ſome the radical or root leaves, including their folioles, approach two feet in length.

The

The flowers are ſnowy white, and their numbers in each ſpike render them very conſpicuous and pretty; they appear in May, June, and July, and thoſe of the firſt and ſecond are ſucceeded by ſeed in autumn, but the third rarely produce any in England.

The ſeed of theſe plants are contained in ſmall berries, the ſize of peas.

Theſe berries are ſuppoſed to be noxious in their quality. A ſingle berry of the common ſort is ſaid to be inſtant death to poultry and other birds.

As furniture for the pleaſure ground, all the three ſpecies may be employed in any of the common compartments, and are adapted for ſhady borders, but not immediately under trees, and may occupy vacant ſpaces between deciduous ſhrubs in the moſt conſpicuous parts of ſhrubberies.

Their propagation may be readily effected by ſeed in the common ground, which may be ſown in the ſpring or autumn; it however is obſervable, that when ſown in autumn, the plants riſe freely the following ſpring, and thoſe of the ſpring ſowing are apt to riſe ſtraggling.

Tranſplant them in autumn where they are to continue, and they will flower the following year.

ACULEUS, (a Needle.) By botaniſts it is expreſſive of a prickle or ſharp point, a ſpecies of armature with which the ſtems and branches of ſeveral plants are furniſhed, exemplified in the roſe, raſpberry, &c.

The prickle here alluded to differs from the ſpine or thorn, *ſpina*, as being only a prolongation or detached portion of the outer bark of the plant, as is apparent by ſuch prickles being readily detached from the ſtem or branch along with the bark; whereas, the ſpine or thorn is more rigid and protruded from the wood of the plant, ſuch as in hawthorn, buckthorn, three-thorned acacia, &c. and cannot be detached without rending ſome part of the ſubſtance of the wood. See SPINA.

ADANSONIA, Æthiopian Sour Gourd, or African Calabaſh-Tree.

This genus furniſhes but one known ſpecies, which is a deciduous tree, of amazing bulk in its native ſoil, which is Africa, and is retained here in ſtoves as a curioſity.

Claſs and order, *Monadelphia Polyandria*.

*Characters.*] CALIX is cup-ſhaped, five-parted at the brim, and deciduous. COROLLA, five roundiſh petals. STAMINA, numerous filaments united below into one body,

and kidney-ſhaped antheræ. PISTILLUM, an oval germen, many-branched ſtyle, having as many hairy ſtigma. PERICARPIUM large, oval, membranous capſule of many cells, filled with a fungous ſour pulp, containing many ſeeds.

The ſpecies is,

ADANSONIA *Baobab.*

*Baobab, or Æthiopian Sour Gourd.*]

The tree is a native of Senegal, and other parts of Africa, where it attains an enormous ſize, adorned with digitate leaves, of three or five ſpear-ſhaped ſpreading lobes.

With reſpect to its merit in this country, we only conſider it merely as a plant of ſingularity, and requires the indulgence of a ſtove. It is propagated by ſeed procured from abroad, which ſhould be ſown in pots, and plunged either in a ſubſtantial hot-bed, under glaſſes, or that in the hot-houſe, in which department the plants muſt be always retained.

There are ſome plants now in England twelve or fifteen feet high.

This monſtrous tree derives its preſent name *Adanſonia*, given by Linnæus, in honour of Mr. Adanſon, an eminent French botaniſt, who travelled in Senegal, and ſaw many of the trees growing, and the deſcription he gives of their enormous bulk is truly amazing.

The diameter of the trunk, he ſays, frequently exceeds twenty-five feet, and its ſpreading top that of a hundred and twenty, and each branch equal to a monſtrous tree in Europe, and the horizontal roots have meaſured upwards of an hundred feet long, and yet, amazing as theſe dimenſions are, the talleſt trees rarely exceed ſixty or ſeventy feet. The age of the tree is perhaps no leſs remarkable than its enormous ſize, for as the ſame gentleman relates, he diſcovered ſome trees about five or ſix feet diameter, on the bark of which were deeply engraved or cut many European names, ſome of which were dated, which inſcriptions he thinks ſufficient to determine pretty near the age the trees may attain, as ſuppoſing thoſe in queſtion, according to the date, grew ſix feet diameter in two hundred years, how many centuries muſt be requiſite to give them the aſtoniſhing diameter of twenty-five feet!

ADENANTHERA, Baſtard Flower-Fence.

The plants are of the tree kind, evergreen, and exotics, of the growth of India, and retained here in ſtoves by way of variety.

Claſs and order, *Decandria Monogynia*, ten ſtamina, one ſtyle.

*Characters.*] CALIX monophyllous, and five-parted at the brim. COROLLA campanulated, and formed of five reflexed petals. STAMINA, ten filaments with roundiſh antheræ. PISTILLUM, an oblong germen, one ſtyle, and ſingle ſtigma. PERICARPIUM, a compreſſed pod, having many ſmooth ſeeds.

The ſpecies are,

ADENANTHERA *Pavonina.*] Adenanthera with decompound or branching ſmooth leaves.

ADENANTHERA *Falcataria.*] Adenanthera with decompound leaves, woolly on the upper ſides.

Theſe trees attain a large ſize in India. Both ſpecies are adorned with large and beautifully branched leaves, the ſingularity of which are the merit of the plants in this country.

They are raiſed from ſeed procured from abroad, and its vegetation muſt be effected by artificial heat, the plants kept in pots, and continued always in the ſtove.

ADIANTHUM, *Capillus Veneris*, or Maiden-hair.

The plants are herbaceous and perennial; there are many ſpecies, one or two of which are admitted in gardens for variety.

This genus is of the claſs *Cryptogamia*, flowers imperfectly viſible.

*Characters.*] The plants are of the fern tribe, whoſe flowers are either entirely concealed or imperfectly viſible, ſee FILICES; which, in the plants in queſtion, are fixed in numerous ſmall ſpots upon the back of the leaves, the points of which are reflexed.

The ſpecies that merit notice are,

[1]ADIANTHUM *Capillus Veneris.*

*True Maiden-hair.*] Adianthum with decompound, alternate, wedge-lobed leaves.

[2]ADIANTHUM *Pedatum.*

*Foot-ſhaped Canadian Maiden-hair.*] Adianthum with foot-ſhaped pinnated leaves with gibbous lobes, and fructifications in the diviſions.

The firſt ſort is a native of France, Italy, and places adjacent; the ſecond of Canada, and both require ſhelter from froſt.

The roots are fibrous and creeping.

With reſpect to their ſtems, they are not to be diſtinguiſhed from the foot-ſtalks or ribs of the leaves, as is common to moſt of the fern tribe, ſee FILICES; they, in both ſpecies, divide into many leaves, which, in the *Capillus Veneris* are like thoſe of coriander, and fragrant and agreeable in taſte.

Both theſe plants are propagated by dividing their roots, which ſhould here be planted in pots of dry ſoil.

ADONIS, *Flos-Adonis*, i. e. Adonis Flower, ſometimes called Bird's-eye.

This genus retains ſeveral ſpecies of herbaceous plants, of the flowery race; two are annual, the others perennial, of ſtature from twelve to twenty inches, and with every ſtalk, branch, and ſhoot, terminated by ſolitary flowers.

Claſs and order, *Polyandria Polygynia.*

*Character.*] CALIX pentaphyllous, coloured, and deciduous. COROLLA, from five to twelve petals. STAMINA, many ſhort filaments, having reflexed antheræ PISTILLUM, many germina and ſtigma. PERICARPIUM none, many naked ſeeds being attached to the pedicle, forming an obtuſe ſpike.

There are five ſpecies; thoſe of note are,

[1]ADONIS *Annua.*

*Common annual red Adonis.*] Adonis with flowers having ſometimes eight petals, theſe red and marked with dark ſpots.

[2]ADONIS *Æſtivalis.*

*Summer flowering yellow annual Adonis.*] Adonis with flowers, having generally five petals, of a pale yellow colour.

[3]ADONIS *Vernalis.*

*Spring flowering yellow perennial Adonis.*] Adonis with large yellow flowers, having about twelve petals.

The two firſt ſorts are annual, i. e. the plants come up, attain their full growth, flower, perfect their ſeeds, and periſh root and branch the ſame year. They are of buſhy growth, from twelve to eighteen inches high, branching every way from the bottom, decorated with abundant foliage, finely cut or divided, and the ends of all the branches and lateral ſhoots are adorned with flowers, which ſtand ſingly.

Theſe two flower in May, June, and July, and the ſeeds ripen in autumn.

The third ſort is perennial in root, which is fibrous, but the ſtalks are renewed annually.

The ſtalks of this riſe eighteen or twenty inches high, ſeveral ariſing from the ſame root, each of which is ſurmounted by a large yellow flower, which appear in April, and the ſeeds ripen in autumn.

All the three ſpecies are proper furniture for

for common borders, or to adorn the fronts of the ſhrubbery compartments, in aſſemblage with other herbaceous plants.

Their propagation is by ſeed in the common ground, ſown in autumn, or early in the ſpring, i. e. February or March. The third ſort alſo by off-ſets of the roots.

The two firſt ſorts ſhould be ſown in the places where it is deſigned the plants are to flower, for they do not ſucceed by tranſplantation; it is moſt eligible to ſow them in ſmall patches, ſee HARDY ANNUALS, covering the ſeed near half an inch deep; when the plants are two inches high, thin them, leaving only three of the ſtouteſt in each patch; their farther culture is occaſional weeding and watering.

If the ſeed of theſe two are ſown in autumn, i. e. September or October, the plants flower earlier by a month or two than thoſe of the ſpring ſowing, as is evident by the plants ariſing from the ſcattered or ſelf-ſown ſeeds.

The following are alſo of this genus.

ADONIS *Apennina.*] Apennine Adonis with large flowers, having fifteen petals.—ADONIS *Capenſis.*] Cape Adonis with doubly ternate leaves, the lobes cut and indented.

ADOXA, *Tuberous Moſchatel,* or Hollow-root.

There is but one ſpecies, a tuberous rooted, hardy, herbaceous perennial, of diminutive growth, eſteemed as a flowering plant.

Claſs and order, *Octandria Tetragynia.*

*Character.*] CALIX, monophyllous, bifid, and permanent. COROLLA, monopetalous, divided into four acute ſegments. STAMINA, eight filaments with roundiſh antheræ. PISTILLUM, the germen reſting upon the calix, ſupporting four ſtyles. PERICARPIUM, a round berry of four cells, containing four ſeeds.

The ſpecies is,

ADOXA *Moſchatellina.*] Moſchatel or Muſk-ſmelling Adoxa, with a bulbous fumitory leaf.

The plant grows wild in woods and ſhady places, and is admitted in gardens more for variety than beauty.

It grows five or ſix inches high, the root is tuberous and pointed, from which riſe ſmall leaves, having many minute lobes, the ſtalk is ſlender, and adorned at top with four or five ſmall whitiſh flowers, which appear in April, and the berries ripen in May.

The propagation of this plant is by the off-ſets of its root, when the leaves decay in ſummer.

It proſpers beſt in the ſhade.

ÆSCHYNOMENE, Baſtard Senſitive Plant.

There are ſix ſpecies, three or four of which are annual, the others perennial, of ſomewhat ſhrubby growth, natives of hot climates, and preſerved here in ſtoves for variety.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX monophyllous, cut into two parts, the upper ſegment bifid, the lower trifid. COROLLA is *papilionaceus*, or butterfly-ſhaped, the ſtandard large and heart-formed, the wings ſhort and oval, and the keel long and moon-ſhaped. STAMINA, ten filaments; nine united, one ſeparate. PISTILLUM, an oblong germen, arched ſtyle, and ſimple ſtigma. PERICARPIUM, an oblong deeply-jointed pod, each articulation having one ſeed.

The ſpecies that merit notice are,

[1]ÆSCHYNOMENE *Aſpera.*

*Rough ſtalked Æſchynomene.*] Æſchynomene with rough herbaceous ſtalks, and deeply jointed rough pods.

[2]ÆSCHYNOMENE *Arborea.*

*Tree Æſchynomene.*] Æſchynomene with a tree-like ſmooth ſtem, ſmooth jointed pods, with the articulations half heart-ſhaped.

[3]ÆSCHYNOMENE *Grandiflora.*

*Great flowered Æſchynomene.*] Æſchynomene with a tree-like ſtem, large flowers, and long ſlender pods.

[4]ÆSCHYNOMENE *Seſban.*

*Ægyptian obtuſe lobed Æſchynomene.*] Æſchynomene with a ſmooth ſtem, leaves having obtuſe lobes, and cylindrical equal pods, not jointed.

The firſt ſpecies is chiefly annual in this country; the others are perennial both in root and ſtem in their native ſoil, and may be continued ſo here by the aid of a ſtove.

They obtain in height from four to ſeven feet, the ſtem of the firſt is herbaceous, and attain four feet height; that of the others is woody, and riſe ſeven feet high, erect, and divide into branches upward, where all the ſpecies are cloſely adorned with leaves, which are univerſally winged, and compoſed of many folioles or lobes, arranged along each ſide of the middle rib. The flowers iſſue from the angles of the leaves; they are compoſed each of four petals, and are of the pea-bloom form, ariſe two or three together, the colour chiefly

yellow, thoſe of the fourth ſort in long pendulous ſpikes, and aſſume a copper colour, appearing in ſummer, and are ſucceeded by long legumenoſe pods in autumn.

The propagation of theſe plants is by ſeed, aſſiſted by a hot-bed in March or April; when the plants are two or three inches high, tranſplant them into ſeparate ſmall pots, and plunge them in the hot-houſe.

ÆSCULUS. The Horſe-Cheſnut-Tree.

There are but two ſpecies and ſome varieties, all of which are hardy deciduous trees, eſteemed principally for purpoſes of ornament in gardens and parks, &c.

Claſs and order, *Heptandria Monogynia.*

*Characters.*] CALIX is monophyllous, and five-parted at the brim. COROLLA, five roundiſh petals inſerted into the calix. STAMINA, ſeven declinated filaments, having erect antheræ. PISTILLUM, a roundiſh germen, ſingle ſtyle, and pointed ſtigma. PERICARPIUM, the calix becomes a large round prickly capſule of three cells, including one or two nuts.

The ſpecies and varieties are,

[1]ÆSCULUS *Hippo-caſtanum.*

*Common Horſe-Cheſnut.*] Æſculus with digitate leaves, having ſeven entire lobes, ſeven ſtamina to the flowers, and prickly capſules.

*Varieties.*] Common Horſe-Cheſnut with gold ſtriped leaves.—Common Horſe-Cheſnut with ſilver ſtriped leaves.

[2]ÆSCULUS *Pavia.*

*Pavia or Scarlet Horſe-Cheſnut.*] Æſculus with digitate leaves, having five or ſix ſawed lobes, red flowers, having eight ſtamina and ſmooth capſules.

The firſt ſpecies is originally a native of Aſia, the ſecond of America, but both ſorts are extremely hardy, and proſper here in any common ſoil or expoſure.

The Common Horſe-Cheſnut and varieties grow thirty or forty feet high. The trees aſſume a formal growth, the branches extending regularly on every ſide, and diminiſh ſo gradually in length from the bottom upward, as to give the head a beautiful conic form, which in ſummer is abundantly furniſhed with luxuriant foliage, and adorned with innumerable large ſpikes of white flowers, tinged with red, ariſing in erect poſition at the extremity of almoſt every ſhoot, which are very conſpicuous at a conſiderable diſtance.

The ſecond ſpecies, Scarlet Horſe-Cheſnut, obtain twelve or fifteen feet ſtature, the branches moderately ſpreading, the flowers are of a red or ſcarlet colour, grow in ſpikes like thoſe of the common ſort, though not ſo large, but make a pretty appearance.

The leaves of both ſpecies are digitate or fingered, and very large; thoſe of the common ſort have ſeven long, broad, obtuſe lobes; but the ſcarlet kind have rarely more than ſix, which in both ſorts unite at their baſe, where they are attached to the foot-ſtalk, and expand like the fingers of a hand.

The flowers of the Common Horſe-Cheſnut appear in May and beginning of June, and thoſe of the other in July.

The nuts of the common ſort ripen plentifully in autumn, but thoſe of the ſecond do not always ripen perfectly in England: they are uſeful only for propagation; deer and ſwine will eat them greedily.

Abroad the nuts of the common ſort are made into meal and given to horſes, hence they derive the name.

The Common Horſe-Cheſnut has been long cultivated for purpoſes of ornament in extenſive gardens, lawns, parks, &c. It was formerly much employed to form avenues and ſhady walks, but the mode of planting theſe trees in long continued lines or ranges, as was the former practice, affords no variety; nor do the trees appear to advantage in that order of arrangement. They have a fine effect placed ſingly and conſiderably detached, their natural form of growth adapts them for this, and may be employed in extenſive places, to form detached clumps of two, three, four, or more trees together, and in ſome places grouped with others of ſimilar growth, placing them in different forms of arrangement to effect variety.

In large ornamental plantations, ſome trees may be interſperſed to advantage toward the front.

If required to adorn avenues, it ſhould always be in aſſemblage with other trees, ſuch as the lime, greater maple, common or Spaniſh cheſnut, and other formal trees with large foliage.

For purpoſes of ſhade the trees are properly adapted, but not as thickets, becauſe when they ſtand cloſe they do not retain their leaves.

The timber of theſe trees being of no value, they do not merit culture on that conſideration.

The Scarlet Horſe-Cheſnut merits a place in

in all ornamental plantations, where they ſhould occupy ſpaces toward the front, and their ſcarlet flowers will effect an agreeable variety.

*Propagation.*

The common ſort may be raiſed plentifully by planting the nuts, and the beſt time is in February, as if planted in autumn many may rot in winter; but until the ſeaſon of planting arrive, it is neceſſary to preſerve them in ſand, to prevent mouldineſs.

The nuts may either be bedded in, or planted in drills, two or three inches deep; the plants will appear in April or beginning of May; by the end of ſummer they will be eight, ten, or twelve inches high, and in autumn or ſpring following they may be tranſplanted in the nurſery way in rows thirty inches diſtant, and half that diſtance from one another in each row.

In this nurſery let them remain four or five years, when, as the plants are of very quick growth, they will be ſix or ſeven feet high, and may then be employed in plantations.

The two varieties with ſtriped leaves may be encreaſed by layers, and by budding or graſting them upon ſtocks of the common ſort.

The ſcarlet ſort may alſo be propagated by planting the nuts; thoſe of American growth are generally the moſt perfectly ripened; however, as the nuts are ſometimes difficult to be procured, the trees may likewiſe be readily encreaſed by budding or grafting them upon ſtocks of the common horſe-cheſnut.

If it is however intended to raiſe them from nuts, the aid of a hot-bed will greatly facilitate their vegetation.

Plant them in pots in the ſpring, and plunge them in the hot-bed. When the plants appear, indulge them with the free air daily, and in a month remove the pots to the full air to remain till October, then place them to have occaſional ſhelter from froſt, and in ſpring tranſplant them in rows in the nurſery.

ÆTHUSA, Fool's Parſley, or Leſſer Hemlock.

As this is a common weed of noxious quality, we only mention it by way of caution, the leaves of which, while young, are ſo like thoſe of common parſley, as not to be diſtinguiſhed without ſome attention, and has often been inadvertently gathered with it, to the fatal experience of many.

To remove all ſuſpicion, it is moſt eligible to cultivate only the curled leaved parſley, which may with facility be diſtinguiſhed from the weed in queſtion.

AGAVE. Great American Aloe, or Agave.

This is the genus of aloes, of which the common opinion prevails that the plants do not flower until they are a hundred years old. They are herbaceous perennials of the ſucculent tribe, exotics of the temperature of the green houſe and ſtove departments, and retained by the curious as plants of ſingularity.

The *Agave* belong to the claſs and order *Hexandria Monogynia.*

*Characters* ] CALIX none. COROLLA, one large funnel-ſhaped petal, divided at the brim into ſix ſegments. STAMINA, ſix long filaments with narrow antheræ. PISTILLUM, an oblong germen placed below the corolla, ſupporting a long ſtyle, having a three-cornered ſtigma. PERICARPIUM, the germen becomes an oblong triangular capſule of three cells, pregnant with compreſſed ſeeds.

There are eight or ten ſpecies; thoſe of moſt note are,

[1]AGAVE *Americana.*

*Common great American Agave.*] Agave with large widely indented leaves, all the denticles ending in a ſharp ſpine, and branching flower ſtem.

*Varieties.*] Common American Agave with gold ſtriped leaves.—Common American Agave with ſilver ſtriped leaves.

[2]AGAVE *Virginiana.*

*Great Virginian Agave.*] Agave with large widely indented ſpinous leaves, and ſimple flower ſtem.

[3]AGAVE *Vera Cruz.*

*Veracrucian broad leaved Agave.*] Agave with large cloſely indented leaves, all the denticles armed with black ſpines.

[4]AGAVE *Rigida.*

*Stiff narrow-leaved Veracrucian Agave.*] Agave with very narrow ſtiff entire leaves, terminated by a black ſpine.

[5]AGAVE *Vivipara.*

*Viviparous, or Childing Agave.*] Agave with reflexed ſlightly indented leaves, and with young plants ſucceeding the flowers.

[6]AGAVE *Fœtida.*

*Stinking Childing Agave.*] Agave with narrow ſtiff entire leaves, and with young plants ſucceeding the flowers.

All the ſpecies are natives of America, the firſt three grow freely here, indulged with the ſhelter of any common green-houſe in

in winter, but the other three ſorts ſucceed beſt in a moderate ſtove during that ſeaſon.

Theſe plants in general are herbaceous, perennial, ſucculent, and evergreen, and of large and ſingular growth, conſiſting entirely of very long, erect, thick, fleſhy leaves, the ſame leaves continuing many years, and all the ſpecies have this ſingularity, they never flower but once, which is rarely till they are upward of fifty, and frequently ſixty, or near an hundred years old, when the flower ſtem is of ſuch amazing rapidity of growth, as in one ſeaſon to attain the height of twenty or thirty feet, ſupporting an enormous pyramid of flowers, continuing ſeveral months; after which ſucceeds the diſſolution of the whole plant; ſtem, leaves, and root totally periſh.

The roots of all the ſorts are thick, fleſhy, and fibrous, ſending forth innumerable ſmall fibres every way.

The plants are acaulis, having no ſtalk or trunk to elevate the leaves, they riſing immediately from the crown of the root in a vaſt cluſter, and attain conſiderable length and ſubſtance, grow erect, and embrace one another at the baſe; thoſe of the centre are cloſely enveloped from bottom to top, which, in different ſpecies, obtain different heights, from eighteen inches to ſix or eight feet, and from one to ſix or eight inches in breadth, and three or four thick, decreaſing gradually in ſubſtance to the extremity, where they terminate in a thorny point; and from between the centre leaves is produced the flower ſtem, which riſes from fifteen to twenty-five feet high; in moſt ſpecies branching out on every ſide pyramidally, and all the numerous ſhoots cloſely adorned with conſiderable cluſters of yellowiſh flowers growing erect, the whole aſſuming a beautiful pyramidal form, of a ſingularly grand appearance, continuing three or four months, and when the flowers fade, they in ſome are ſucceeded by ſeed, in others, inſtead of ſeed, by young plants, in the place of proper ſeed veſſels.

The ſeed however never comes to maturity in England, but the young plants attain it fully.

The firſt, ſecond, and third ſpecies, and varieties, obtain conſiderably the largeſt growth, their leaves often growing five or ſix feet high and upward, particularly the two former; the ſecond is diſtinguiſhable from the firſt by the leaves being of a paler green, and much narrower upward; and the third from both theſe by the leaves being broad, thinner, and the indentings on the edges more frequent and ſlight, and the armature or ſpines very black.

The *Common great Agave* and *Agave Virginiana*, have flowered frequently in many parts of England; the ſtem of the former always branches pyramidally, and that of the latter is ſimple, and ſupports its flowers entirely at its ſummit in a vaſt cluſter.

The two varieties of the *Common Agave* with ſtriped leaves are plants of ſingular beauty, and merit particular attention.

The fourth ſpecies, *Agave Rigida*, is of moderate growth, the leaves rarely exceed an inch and half in breadth, and eighteen or twenty in length, they are of ſtiff texture, the outward ones ſpreading horizontally.

The fifth and ſixth ſorts, *Agave Vivipara* and *Fœtida*, hath great ſingularity, that in the former, though the plant itſelf rarely exceeds eighteen inches or two feet, it produces a flower ſtem ten or twelve high, and in the latter, though it is ſeldom more than a yard high, the flower ſtem often attains ſix or ſeven times that height; and what is ſtill as remarkable, the flowers, inſtead of being ſucceeded by proper ſeed veſſels, are productive of young plants, hence they derive the name Childing Aloe.

Both theſe have flowered in England, and produced numbers of young plants on their flower ſtems as above, which being planted, readily grow.

Of the flowering of all theſe plants, it is the common opinion that they do not effect it until they attain the age of a century; the time of their flowering however is not limited, but depends upon the growth of the plant, which is particularly affected by heat and cold, for as the flower ſtem being produced from the centre of the leaves, and theſe cloſely embrace one another, it is evident, that until they are fully expanded, the bud of the ſtem is not at liberty to advance; and in this climate, by reaſon of cold, the growth of the plants being remarkably ſlow, it is often near an hundred years before they effect that expanſion; when the ſtem however begins to appear and advance, it makes ſurpriſing progreſs, as in the ſpace of three or four months it acquires its full ſtature.

*Propagation and Culture.*

The firſt and ſecond ſpecies and varieties are productive of abundant off-ſets or ſuckers from their baſe, by which they may be propagated with great facility. Theſe ſuckers may be taken off any time in ſummer, and planted

planted ſingly in ſmall pots of light ſandy earth; give a little water, and they will take root freely without trouble.

The third and fourth being ſparingly productive of ſuckers, they, in default of which, may be increaſed by planting pieces of their large roots in pots, and plunge them in a moderate hot-bed, they will put forth fibres in the earth, and ſhoots above, and form proper plants in three months. The fifth and ſixth ſorts are as ſparing of ſuckers as the two former, but in lieu of which they produce young plants on their lofty flower ſtems; but until they flower, thoſe cannot be obtained, their propagation therefore may alſo be tried by pieces of the root and leaves as above.

It is to be remarked, that in reſpect to ſoil, all the ſorts require a dry light ſandy earth, becauſe the plants themſelves being very ſucculent and humid, a ſoil that retained moiſture would rot the roots in winter.

With reſpect to their general culture, they muſt always be retained in pots or tubs. The firſt, ſecond, and third ſorts, and varieties, ſucceed in the full air from May until the end of October, when they ſhould be placed in the green-houſe, but the fourth, fifth, and ſixth ſorts are of the moſt proſperous growth when they have the conſtant protection of a ſtove. And it is to be particularly obſerved, that as all theſe plants are extremely ſucculent and replete with moiſture, they require very little water in winter, particularly thoſe in the green houſe; but in hot dry weather in ſummer ſhould have moderate waterings twice a week.

According as the plants advance in growth they ſhould be indulged with larger pots, but never any too large, except the great ſorts, which, when they attain a large ſize, ſhould be ſhifted into tubs for the convenience of moving them. See SHIFTING PLANTS.

It is neceſſary to ſhift all the ſorts once in two years at leaſt into freſh earth, ſee SHIFTING PLANTS.

When the plants make an effort for flowering, it is diſcoverable by the centre leaves expanding, and the bud of the future ſtem appearing, which, if it do not advance freely, it may be forwarded by artificial heat; a deep trench or pit filled with hot dung or tanner's bark, or a mixture of both, raiſing it two or three feet; into which plunge the pot or tub, containing the plant, and ſupply it with water, obſerving if the plant is at this time in any place of ſhelter, way muſt be made upward, if neceſſary, for the ſtem to advance; and if the weather is cold, it muſt not be expoſed, ſo that a temporary awning ſhould be erected to ſhield it occaſionally.

As ſome of theſe plants acquire a very conſiderable ſize, and take up much room in a green-houſe, and being troubleſome to move, a few ſhould only be cultivated to grow large.

Sometimes the great ſorts grow ſo very large and weighty before they arrive at a flowering ſtate, that the tubs containing them are obliged to be fixed upon ſtrong frames with low wheels, for the convenience of moving them out and in to the green-houſe.

The following are the other leſs common ſpecies of Agave.

[1]AGAVE *Karrata.*] Karrata Agave with long erect dark green leaves, edged with brown, and ſlightly ſawed.

[2]AGAVE *Tuberoſa.*] Tuberous rooted Agave with long narrow indented ſpinous edged leaves.

[3]AGAVE *Serrata.*] Serrated green Agave.

AGERATUM, Baſtard-Hemp Agrimony.

The plants are herbaceous, there are three or four ſpecies, one of which only claim eſteem, which is a hardy perennial, that attains three or four feet ſtature, terminated by ſnowy heads of flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] The flower is compound. CALIX, the common cup is oblong and ſcaly. COROLLA, compoſed of ſeveral hermaphrodite tubular florets. STAMINA, five filaments with the antheræ united. PISTILLUM, an oblong germen, ſlender ſtyle, and two ſmall ſtigma. PERICARPIUM none, each germen becomes a ſeed crowned by a minute five-parted cup, placed in a naked receptacle.

The ſpecies that merit attention is,

AGERATUM *Altiſſimum.*

*Tall Canadian Ageratum.*] Ageratum with a tall ſmooth ſtalk, oval heart-formed rough leaves, and alternate flower branches.

This plant is perennial in root, but the ſtalks riſe annually in ſpring, flower in the end of ſummer, and periſh in autumn.

The roots are fibrous and ſpreading.

The ſtalk riſes four or five feet high, furniſhed upward with many ſide-branches, decorated with leaves, and terminated by large tufts of white flowers, appearing about Michaelmas, and continue three weeks, and are ſometimes ſucceeded by ripe ſeeds.

It

It is proper furniture for ſuch compartments where tall plants are required.

The propagation of this plant is by ſeed, and by parting the roots; by the latter it encreaſes conſiderably, and may be performed in autumn, or early in ſpring.

AGGREGATUS *Flos.* An Aggregate Flower.] This conſiſts of a number of ſmaller flowers or florets, collected into one head by means of ſome part common to the whole, ſuch as one common receptacle and calix or cup; that in the proper aggregate flower each ſeparate floret or fructification are erected on a ſhort foot ſtalk, ſtanding on the receptacle or baſe, which is extended in breadth for that purpoſe; and in many aggregate flowers, the florets, beſides the common calix, are each furniſhed with a proper cup.

From the different ſtructures, diſpoſition, and other circumſtances of theſe common parts, the receptacle and calix ariſes a ſevenfold diviſion of aggregate flowers, viz.

[1]The AGGREGATE Flower, properly ſo called; ſuch as ſcabious, globularia, cephalanthus, thriſt, &c.

[2]The COMPOUND Flower; ſuch as ſunflower, marigold, African marigold, milfoil, eupatorium, &c. See COMPOSITUS *Flos.*

[3]The UMBELLATE Flower; ſuch as ferula or fennel-giant, bupleurum or hare's-ear, eryngium, parſley, angelica, lovage, &c. See UMBELLATÆ.

[4]The CYMOSE Flower; ſuch as honeyſuckle, gelder-roſe, lauruſtinus, elder, &c. See CYMA.

[5]The AMENTACEOUS Flower or Catkin; ſuch as that of the pine-tree, poplar, beech, birch, walnut, cypreſs, hazel, willow, &c. See AMENTACEOUS FLOWER.

[6]The GLUMOSE Flower; ſuch as that of wheat, oats, reed, Turkey wheat, and all the graſſes. See GLUMOSE FLOWERS.

[7]The SPADICEOUS Flower, protruding their heads of flowers from a ſpatha or ſheath; ſuch as the narciſſus, amaryllis, colchicum, ſnow drop, aſphodel lily, blood flower, ſea-daffodil or pancratium, garlick, onion, leek, &c. See SPADICEUS, SPADIX, &c.

For a particular deſcription of each of the above ſpecies of aggregate flowers, ſee each in its proper place.

AGRIMONIA, Agrimony.

This genus furniſhes five herbaceous perennials, that obtain from eighteen inches to three feet ſtature; two or three proper for ornament, the others for medical purpoſes.

Claſs and order, *Dodecandria Digynia.*

*Characters.*] CALIX, one leaved, cut into five acute parts, and ſits on the germen. COROLLA, five plane petals inſerted into the calix. STAMINA, twelve filaments with double antheræ. PISTILLUM, a germen placed under the flower, ſupporting a double ſtyle. PERICARPIUM, the germen becomes two roundiſh ſeeds attached to the calix.

The ſpecies are,

[1]AGRIMONIA *Eupotaria.*

*Common officinal Agrimony.*] Agrimony with winged cauline leaves, having ſmall ſawed lobes and rough ſeed.

[2]AGRIMONIA *Repens.*

*Creeping-rooted Eaſtern Agrimony*] Agrimony with thick creeping roots, winged, cauline leaves, having narrow lobes, ſhort ſpikes, and hairy ſeeds.

[3]AGRIMONIA *Odorata.*

*Odoriferous Agrimony.*] Talleſt Agrimony with pinnated cauline leaves, having many oblong ſharply-ſawed lobes.

[4]AGRIMONIA *Agrimonoides.*

*Agrimonoides, or Three-leaved Agrimony.*] Agrimony with cauline leaves, having three lobes, and ſmooth ſeed.

The plants have fibrous roots, which are perennial, from which ariſe ſeveral branching leafy ſtalks annually in ſpring, and decay in autumn, after they have flowered and perfected ſeed.

The firſt ſort grows wild in woods and uncultivated ſhady places, but is retained ſometimes in gardens as a medicinal herb.

The ſtalks of the ſecond ſort riſe near two feet high; the third, double that height; and the fourth, near a yard; and the ſtalks of each ſort are branching, and cloſely adorned with ſmall winged leaves, and terminated by ſpikes of flowers. The third ſort is in much eſteem for the odoriferous property of its leaves and flowers. All the three ſpecies may be retained as furniture for common borders, and ſuch places where many plants of eaſy culture are required, as they ſucceed in any expoſure, and will effect an agreeable diverſity in aſſemblage.

The propagation of all the ſorts is effected by ſeed, and by parting the roots in autumn, or early in ſpring, but as they multiply exceedingly by roots, that is the moſt expeditious method.

AGROS-

AGROSTEMMA, Wild Lychnis, or Campion, Roſe Campion.

The plants are herbaceous perennials, there are three or four ſpecies, one of which produce beautiful garden flowers, the others have no merit.

Claſs and order, *Decandria Pentagynia*, ten ſtamina, five ſtyles.

*Characters.*] CALIX, monophyllous, tubular, five-parted at the brim, and permanent. COROLLA, five broad expanded petals. STAMINA, ten filaments, five of which are inſerted alternately into the baſe of the petals. PISTILLUM, an oval germen, five ſtyles, having ſingle ſtigma. PERICARPIUM, an oval capſule of one cell, having five diviſions pregnant with ſeeds.

The ſpecies and its varieties are,

AGROSTEMMA *Coronaria.*

*Coronated Agroſtemma, or Common Roſe Campion.*] Agroſtemma with ovate, ſpear-ſhaped, woolly leaves, and coronated undivided petals.

*Varieties.*] Single Roſe Campion with pale red flowers.—Single Roſe Campion with deep red flowers.—Single Roſe Campion with white flowers.—Single Roſe Campion with white and red flowers.—Double Roſe Campion with a large crimſon flower.

All the above varieties are extremely hardy fibrous-rooted perennials, that ſucceed in any common ſoil of a garden, and are of eaſy culture.

They grow eighteen inches or two feet high, the leaves are hoary and whitiſh, and riſe from the root in a great tuft, and remain all the year; and from the centre is produced the flower-ſtem annually in the ſpring, which rarely exceeds two feet ſtature, divides into many branches, all of which are terminated by the flowers in July and Auguſt, which, in the ſingle kinds, are ſucceeded by numerous ſeeds, but the double ſort produce none.

The flower of the common ſingle kinds have only five petals, but thoſe of the double ſort are numerous, even to the excluſion of the parts of fructification, ſo that they conſequently produce no ſeed.

The Double Roſe Campion is a moſt elegant flower, and the ſingle kinds, though of inferior beauty, form a pretty variety.

The ſingle kinds riſe plentifully from ſeed ſown in a bed of common earth, in ſpring or autumn; when the plants are two or three inches high, prick them into another bed or border, ſix inches diſtance, giving occaſional watering; and in autumn or ſpring following tranſplant them into the borders for flowering, which they will effect the enſuing ſummer.

As the old plants are apt to grow ſtraggling, it is proper to raiſe a ſupply of young ones every year.

They alſo riſe plentifully from ſcattered ſeeds.

The double ſort, producing no ſeed, can only be propagated by parting the roots, they generally afford plenty of off-ſets, which ſhould be parted in autumn as ſoon as the flower is paſt; plant them in a bed of common earth, ſix inches a-part, to remain until ſpring; then tranſplant them where they are to flower.

Some plants may with propriety be cultivated in pots, to adorn court-yards.

AIR. In vegetation, air, heat, and water, are its principal agents: Air abounds with vegetable ſubſtances, neceſſary to the growth and welfare of all ſeeds and plants; and it has been proved by numerous experiments, that without a certain portion of Air, no ſeeds can germinate, nor plants grow freely, nor ſeeds and fruits attain due perfection.

Air enters into the bowels of the earth to a certain depth; thence into the pores of ſeeds, roots, and veins of the very trees and herbs, carrying along with it thoſe vegetable ſubſtances contained either in itſelf, or lodged in the earth; and even enters through the bark and body of the trees, and materially effects their branches, leaves, flowers, and fruit.

The humidity of the Air alone often makes many ſorts of ſeeds riſe, and roots and plants ſhoot, that are expoſed to it; ſeeds and plants too are often obſerved to vegetate in water, without the intervention of earth; but either of theſe without Air is inſufficient. Many ſucculent plants, by the aſſiſtance of Air only, will retain their growing quality ſeveral months; and ſome ſorts of aloes will live without earth and water ſome years, if ſecured from froſt, particularly exemplified in the *Aloe Barbadenſis:* and the branches of ſome ſorts of *Sedum* and *Sempervivum,* being cut off in ſummer and expoſed to the Air, have been obſerved to emit roots without the aid of earth and water, and live ſeveral months; the *Sempervivum Arboreum* particularly furniſh examples.

Air in a certain degree is moſt neceſſary to preſerve the vegetative faculty of ſeeds, previous to their being committed to the earth;

as for example, if ſeeds are put into phials or bottles, cloſe ſtopped, and ſealed down, and retained therein ſeveral months, they, for want of air to nouriſh and preſerve health in the germ, loſe their germinating quality.

Thus, for want of a due portion of Air, ſeeds which are buried to too great a depth in the earth, either thrive but indifferently, or do not grow at all.

They frequently preſerve, however, their germinating virtue for many years in the bowels of the earth; and it is not unuſual upon a piece of ground being newly dug to a conſiderable depth, to obſerve it ſoon after covered with plants, which had not been ſeen there in the memory of man. How the vegetative property is ſo long maintained in ſeeds ſo deeply immerſed in the ground, is hard to account for; but certain it is, that there have been inſtances of ſeeds having been buried ſeveral feet deep upwards of thirty years, and when turned up again to the air, they germinated like new ſeeds; and ſoil that have been taken out of the bottom of wells, vaults, and ſewers, and ſpread in the Air, have produced many unknown weeds or plants.

It is obſervable of trees and plants, whoſe roots are planted a conſiderable depth, that being out of the reach of the proper influence of Air, ſun, and ſhowers, they do not proſper.

The ſame is alſo very obvious in plants growing in garden-frames under glaſſes, and in green-houſes and ſtoves: if they are kept too cloſe, they do not proſper; and if deprived of a proper current of Air, they draw up ſeeble, become meagre, dwindle, and die before their uſual time. Great attention ought therefore to be at all opportunities obſerved, to admit the freſh Air to plants retained in thoſe departments. Common hardy plants, that require only protection of frames from froſt in winter, ſhould be fully expoſed every mild day, by taking off the covers: thoſe of tender quality, that need artificial heat, and continual ſhelter of frames and glaſſes, ſuch as early cucumbers, melons, and tender annuals, &c. although they are unable to endure the full Air till June, ſhould be indulged with a due portion thereof every day, even in froſty weather, if there is heat in the beds; which is effected by raiſing on props one end of the lights, from half an inch to three in height, according to the temperature of the beds, and that of the outward Air. Green-houſe plants, during the winter ſeaſon, ſhould be allowed free air every mild calm day, by opening the windows leſs or more: and ſtove plants ſhould alſo have the indulgence of freſh Air in mild, ſunny, calm days; even occaſionally in winter, when the ſun ſhines warmly.

Plants in general proſper beſt where they enjoy the full Air in as great a degree as their reſpective temperaments will admit. All hardy kitchen-garden vegetables attain the greateſt perfection in a free expoſure: as for example, if peas, beans, cabbages, &c. are planted under ſpreading trees, or in any cloſe or ſhady place where they are deprived of a proper current of Air, they draw up weak without taking the proper conſiſtence, and do not attain half the perfection, neither in quantity nor quality, as thoſe that are more expoſed.

Fruit likewiſe that are produced in orchards where the trees and branches are ſo crowded as to exclude the proper circulation of Air, never attain due perfection, neither in ſize, colour, nor reliſh.

AJUGA, Bugula, or Bugle.

The plants are herbaceous perennials, of the ornamental kind, of ſtature from ſix to twelve inches, adorned at top with many flowers collected into whorled ſpikes.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX is one-leaved, cut into five ſegments. COROLLA, monopetalous, tubular, and labiated, the tube long and incurved, the upper lip ſhort and bifid, the under one large, and three-parted. STAMINA, two ſhort, two long filaments, and double antheræ. PISTILLUM, four germina elevating one ſtyle, having two ſtigma. PERICARPIUM none, four ſeeds lodged in the calix.

There are ſeven or eight ſpecies, thoſe that demand notice are,

[1]AJUGA *Reptans.*

*Creeping common blue Bugle.*] Bugle with obovate crenated leaves, half embracing the ſtalk, creeping ſide ſhoots emitting roots, and blue flowers.

*Varieties.*] Common Bugle with purple flowers.—Common Bugle with white flowers.

[2]AJUGA *Decumbens.*

*Declinated Alpine Bugle.*] Bugle with oblong oval leaves, reclining ſtalks, and the whorls of flowers remote.

[3]AJUGA *Pyramidalis.*

*Pyramidal blue Bugle.*] Bugle with a ſimple ſtalk, oval bluntly indented leaves, and cloſe pyramidal blue ſpike.

*Varieties.*]

*Varieties.*] Pyramidal red Bugle.—Pyramidal white Bugle.

[4]AJUGA *Genevenſis.*

*Geneva Bugle.*] Bugle with oblong woolly leaves, hairy calix, and fleſh coloured flowers.

*Variety.*] Geneva white Bugle.

[5]AJUGA *Orientalis.*

*Eaſtern inverted white Bugle.*] Bugle with oval, indented, hairy, cloſe ſitting leaves, and inverted white flowers.

*Variety.*] Eaſtern inverted blue Bugle.

They are all of humble growth, the roots fibrous and creeping; the ſtalks riſe from ſix to twelve inches high, emitting trailing, rooting ſhoots, and decorated with ſmall, ſimple, ovate leaves below, and many ſmall flowers upward, collected into whirls round the ſtalk, in ſome forming a cloſe ſpike.

They flower early in ſummer, and yield plenty of ſeed.

The *Common Bugle* grows naturally in woods in England, the next three on the Continent, and the fifth in the Levant.

The former four ſucceed in any common ſhady border, the fifth ſhould be potted and ſhielded from froſt.

The propagation of all the ſorts is by off-ſets, or ſide ſhoots, which root in the earth, and may be ſeparated at any time, or may be raiſed from ſeed.

ALATERNUS. See RHAMNUS.

ALBUCA, Baſtard Star of Bethlehem.

This genus furniſhes two ſpecies of bulbous-rooted herbaceous perennials, of the flowery tribe, whoſe flower-ſtalks riſe from eight to fifteen inches high.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX none. COROLLA, ſix oblong oval petals, three of which expand, and three ſtanding inward and connected. STAMINA, ſix long trigonous filaments, three of which are alternately caſtrated, the others are crowned with moveable antheræ. PISTILLUM, an oblong triangular germen and ſtyle, ſurmounted by a conic triangular ſtigma. PERICARPIUM, the germen ripens to a three-cornered capſule of three cells, containing many ſmall ſeeds.

The ſpecies are,

[1]ALBUCA *Major.*] Greateſt Canadian Albuca, with ſpear-ſhaped leaves.

[2]ALBUCA *Minor.*] Leaſt African Albuca, with narrow awl-ſhaped leaves.

Both theſe ſpecies have moderately large bulbous roots, from which the leaves and flower-ſtem riſe annually; the leaves riſe firſt, which are long and narrow, and the ſtem riſes in the centre of them, ornamented with yellowiſh flowers of the liliaceous tribe, appearing towards autumn, but rarely ripen ſeeds in England.

In the firſt ſpecies the ſtem riſes twelve or fifteen inches high, decorated with many drooping flowers, forming a looſe ſpike.

The ſecond grow eight or ten inches high, ſurmounted by a few erect flowers, forming a ſort of corymbus.

Both the ſpecies require protection from froſt, ſo the roots ſhould be retained always in pots, and placed in a frame in winter, to have occaſional ſhelter.

Their propagation is by off-ſets from the roots, when the flower is paſt in ſummer.

ALCEA, Hollyhock, or Roſe Mallow.

This genus furniſhes many curious varieties of hardy herbaceous perennials, of the flowery race, whoſe flower-ſtem obtains a lofty ſtature, adorned with numerous large and elegant roſe like flowers.

Claſs and order, *Monadelphia Polyandria.*

*Characters.*] CALIX, two monophyllous cups, the inner ſlightly five-parted, the outer ſix, and expands. COROLLA, five large expanded petals. STAMINA, numerous filaments united below, with the ſtyles like a column, and kidney-ſhaped antheræ. PISTILLUM, a round germen, a ſhort ſtyle, many-parted at top, having as many ſtigma. PERICARPIUM, the germen ripens to a round, depreſſed, jointed capſule of many cells, each containing one ſeed.

There are only two diſtinct ſpecies, but of which are many beautiful varieties, of various colours, ſuch as whites, all the tints of red and purple, and almoſt every degree of yellow, and of each variety there are ſingle and double flowers.

The ſpecies and principal varieties are,

[1]ALCEA *Roſea.*

*Common Hollyhock, or Roſe Mallow.*] Hollyhock with rounded and angularly ſinuated leaves.

*Varieties.*] Hollyhock with white flowers.—Cream coloured Hollyhock.—Fleſh coloured Hollyhock.—Red Hollyhock.—Flaming red Hollyhock.—Blackiſh red Hollyhock.—Purple Hollyhock.—Pale yellow Hollyhock.—Deep yellow Hollyhock.—Variegated Hollyhock.

[2]ALCEA *Ficifolia.*

*Fig-leaved or Palmated Hollyhock.*] Hollyhock with palmated or hand-ſhaped leaves.

*Varieties.*] Several of different colours, as thoſe of the former.

Both theſe ſpecies and reſpective varieties are hardy perennials, that proſper in any common ſoil and ſituation; they are perennial in root, but the ſtalks are annual, they riſing in ſpring attain ſix or eight feet ſtature, flower in July and Auguſt, perfect ſeeds in September, and ſoon after periſh.

The roots are fibrous, white, long, and ſpreading, but not furniſhed with many ſmall fibres.

The leaves are both radical and elevated on the ſtem, ſimple, and from three to eight or nine inches broad, the radical or root-leaves riſe in a great cluſter.

The ſtem riſes between the radical leaves, immediately from the root; is round, erect, and grows two or three yards high, ornamented on every ſide with leaves and flowers, forming a ſpike from three to five feet in length, the flowers making their firſt appearance when the ſtalk is about a yard high, and as that advances, furniſhes a daily ſupply of more new flowers, for ſix or eight weeks, which make a fine appearance.

All the varieties, both ſingle and double, afford plenty of ſeed for propagation.

The flowers in their ſingle ſtate have but five petals, but thoſe of the doubles are numerous, and the flower equal in bigneſs to the largeſt double Provence roſe; in ſome, the outer petals are large and ſpreading, thoſe within ſmall, and form a globular body in the middle.

There are different degrees of doubleneſs, with reſpect to the quantity and diſpoſition of the petals, but thoſe fully double have ſingular elegance.

*Uſe in Gardens, Culture, &c.*

All the varieties of theſe plants are very ornamental to the pleaſure ground, although they are often diſregarded by the incurious, but we know very few herbaceous plants that equal them in beauty as garden flowers for ornament, eſpecially when their tall ſtems are duly ſupported and trained in erect poſition.

The propagation of all the varieties is eaſily effected by ſeeds ſown in a bed of common earth, in March or April; the plants appear in a few weeks, and will be fit to tranſplant in autumn.

The firſt year the plants produce only radical or root-leaves; the ſecond, they ſhoot up their ſtalks and flower.

In ſowing theſe ſeeds, it is eligible, as they are pretty large, to draw flat ſhallow drills for their reception, half an inch deep, and ſix aſunder; ſow the ſeed thin and regular, rake the earth over them, and trim the ſurface ſmooth: the plants will appear in a month; and in July, when they will have ſeveral leaves, tranſplant them into a nurſery-bed, nine inches diſtance, and give occaſional waterings for a fortnight.

In October, November, or ſpring following, tranſplant them into the borders and other open compartments of the pleaſure ground, ſhrubbery, &c.

We obſerved formerly that the plants are perennial in root, but we would be underſtood, that although the ſame individual continues many years, it never flowers ſo ſtrong, nor are the flowers ſo large, double, and lively in colour as the firſt and ſecond year. Perſons that are curious ſhould therefore raiſe a ſupply annually from ſeed.

Always, if poſſible, have regard to procure ſeed ſaved from the beſt double flowers.

ALCHEMILLA, Ladies-Mantle.

This genus retains ſeveral ſpecies of hardy herbaceous perennials, ſome of which merit culture for the ſingularity of their leaves, which are curiouſly ſcalloped, waved, and plaited.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX is monophyllous, eight-parted, ſpreading at the brim, and permanent. COROLLA none. STAMINA, four filaments attached to the brim of the calix, having yellow antheræ. PISTILLUM, an oval germen, long ſtyle, and globular ſtigma, and the germen ripens to a ſingle ſeed.

The ſpecies are,

[1] ALCHEMILLA *Vulgaris.*

*Common Ladies-Mantle.*] Alchemilla with roundiſh, lobated, ſawed leaves.

[2] ALCHEMILLA *Minor.*

*Leaſt Ladies-Mantle.*] Alchemilla with roundiſh, lobated, plaited, ſharply ſawed, ſilvery leaves.

[3] ALCHEMILLA *Pentaphylla.*

*Five-leaved fimbricated Alchemilla.*] Alchemilla with five-lobed leaves, the lobes finely cut like fringes.

[4] ALCHEMILLA *Alpina.*

*Alpine digitate Alchemilla.*] Alchemilla with digitate or fingered, hoary, ſawed leaves.

All four ſpecies are hardy, fibrous-rooted, herbaceous perennials, that proſper in any common

common ſoil and expoſure, have perennial roots, but the leaves and ſtalks are renewed annually.

The leaves are the principal merit of the plants, for purpoſes of ornament in gardens; they riſe immediately from the root on long foot-ſtalks, thoſe of the firſt and ſecond are roundiſh, broad, and ſcalloped into ſeveral lobes, which are waved and plaited, hence the plants derive the name Ladies-Mantle.

The flower-ſtem riſes between the leaves, ten or fifteen inches high, very branching, having all the branches terminated by cluſters of flowers, which being apetalous, make no figure.

The *Common Alchemilla*, ſecond and third ſorts, grow wild in meadows and mountainous places, and are admitted in gardens for variety.

The propagation of all the ſpecies is by parting the roots, and by ſeed ſown in a ſhady border.

The *Alchemilla Vulgaris* is a medicinal plant.

ALETRIS, Guinea Aloe, &c.

The plants of this genus are herbaceous, ſucculent evergreens, of the aloeaceous tribe, natives of hot climates, and retained here in ſtoves for curioſity.

Claſs and order, *Hexandria Monogynia*, ſix ſtamina, one ſtyle.

*Characters.*] CALIX none. COROLLA, one oblong oval liliaceous petal, ſix-parted at the brim. STAMINA, ſix long filaments inſerted in the corolla. PISTILLUM, an oval germen, awl-ſhaped ſtyle, and trifid ſtigma. PERICARPIUM, a trigonous capſule of three cells, and angular ſeeds.

There are five or ſix ſpecies; thoſe of note are,

[1]ALETRIS *Hyacinthoides.*

*Hyacinth-flowered Guinea Aletris.*] Aletris without ſtalk, ſpear-ſhaped fleſhy leaves, and flowers proceeding by pairs.

[2]ALETRIS *Zeylanica.*

*Ceylon dwarf Aletris.*] Aletris without ſtalk, and ſpear-ſhaped, plane, erect leaves.

[3]ALETRIS *Capenſis.*

*Cape undulate Aletris.*] Aletris without ſtalk, ſpear-ſhaped undulate leaves, and oval ſpike of nodding flowers.

[4]ALETRIS *Fragrans.*

*Fragrant ſtalky Aletris.*] Aletris with an erect ſtalk, elevating a head of ſpear-ſhaped leaves, embracing it with their baſe.

Theſe plants have the appellation of aloes among gardeners, derived from their ſimilarity of growth, particularly the two firſt, i. e. Guinea Aloe, and Ceylon Aloe.

The roots of all theſe plants are thick, fleſhy, fibrous, and creeping.

The firſt three ſorts are acaulous plants, i. e. having no ſtem nor foot-ſtalk to elevate the leaves, they riſing immediately from the root, and without any viſible foot-ſtalk of their own; are narrow, ſtiff, fleſhy, and grow from ſix to eighteen inches in length, and the flower-ſtem riſes between the leaves, alſo from the root, attaining the ſame height, decorated with many bright white liliaceous flowers, of the hyacinth form, arranged in a ſort of ſpike.

In the former, the leaves and ſtem riſe a foot and half high, and produce many flowers; the ſecond riſe but ſix or eight inches, and rarely flower here; and the third attain a foot in height, and flowers annually.

The fourth ſort is furniſhed with an erect, ſucculent, jointed ſtalk, that obtains three or four feet ſtature, elevating a cluſter or head of thin reflexed leaves at top, and from their centre proceeds the flower-ſtem, ariſing two feet high, branching each way, and beautifully decorated with numerous fragrant white flowers.

All theſe plants, being exotics of delicate temperature, muſt be conſtantly kept in pots, and retained always in the ſtove.

The propagation of all the ſorts is by offſets or ſuckers, which in the two firſt ariſe plentifully from the root, in the fourth from the ſides of the ſtem, and may be taken off in ſummer, planted in ſmall pots of ſandy earth, and plunged in the bark-bed.

ALLEYS, in Gardening, Alleys are narrow paths between beds, borders, and other garden compartments, deſigned principally for the convenience of going between ſuch compartments, to do what is neceſſary to the plants, and gather their produce: Alleys are alſo ſometimes intended both for uſe and ornament in flower gardens.

In kitchen gardens, where a border is carried round next the main walks, it ſhould be divided from the quarters by a two feet Alley, for the convenience of carrying in dung and water; and the large quarters ſhould alſo be divided by one or two croſs Alleys for the ſame purpoſe.

The proper width of Alleys between beds, is from one to two feet; as, for example, Alleys between aſparagus beds ſhould be two feet wide; thoſe between ſtrawberries, a foot and

and half; and between beds of aromatic herbs, fifteen inches: but between beds of onions, leeks, carrots, parſnips, lettuce, endive, and other ſmall crops, ten or twelve inch wide Alleys is ſufficient; the ſame alſo between beds of ſeedling cabbage, ſavoys, and cellery, for the convenience of going in to draw the plants for tranſplantation.

In flower gardens, Alleys are often deſigned both for uſe and ornament. Between beds of tulips, hyacinths, ranunculas, anemonies, and other flowers that are bedded, the Alleys ſhould be eighteen inches wide; and to have them ornamental, the beds ſhould be edged with box, and the Alleys filled with the beſt high-coloured fine gravel; or in default of that, with ſand or ſhells.

ALLIUM, Garlick, Onion, and Leek, &c.

By the laws of Linnæan botany, the onion and leek are retained as ſpecies of Allium, or garlick, and we ſhall treat of them accordingly; but, for diſtinction ſake, ſhall firſt proceed with the garlick kind; then with that of the onion, *Allium Cepa*; next with the leek, *Allium Porrum*.

Claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX, is a ſpatha ſerving as a general cup, protruding many flowers. COROLLA, each is compoſed of ſix oblong erect petals. STAMINA, ſix ſubulated filaments, elevating as many oblong antheræ. PISTILLUM, a trigonous germen, ſimple ſtyle and ſtigma. PERICARPIUM, a triangular capſule of three valves, and cells pregnant with roundiſh ſeeds.

Of the garlick kind there are upwards of thirty ſpecies, but many of them being plants of no merit, we ſhall only notice thoſe proper for œconomical purpoſes, and for ornament in gardens.

The ſpecies are,

[1]ALLIUM *Sativum*.

*Common officinal Garlick.*] Allium with compound bulbs, and plane cauline leaves.

[2]ALLIUM *Scorodoprasum*.

*The Rocambole.*] Allium with plane, indented, cauline leaves, two edged vagina, and ſtalk terminated by a head of bulbs.

The above two are officinal plants.—The following are of the flowery kind.

[3]ALLIUM *Moly*.

*Common yellow Moly.*] Allium with broad, ſpear-ſhaped, radical leaves, a naked and nearly cylindrical ſtalk, and flat yellow umbels.

[4]ALLIUM *Subhirſutum*.

*Hairy white Moly of Dioſcorides.*] Allium with plane cauline leaves, hairy below, awl-ſhaped ſtamina, and white umbels.

[5]ALLIUM *Sphærocephalon*.

*Spherical-headed purple Moly.*] Allium with a taper ſtalk, half-taper cauline leaves, long three-pointed ſtamina, and round purple umbels.

[6]ALLIUM *Roſeum*.

*Roſe-coloured Montpelier Garlick.*] Allium with linear radical leaves, naked ſtalk, ſhort pedicles, oval petals, ſhort ſtamina, and roſe-coloured umbels.

[7]ALLIUM *Flavum*.

*Straw-coloured pendulous Moly.*] Allium with taper cauline leaves, oval petals, long ſtamina, and pendulous pale yellow flowers.

[8]ALLIUM *Magicum*.

*Great purple Moly.*] Allium with plane cauline leaves, ſimple ſtamina, and bulbs growing in the branches of the umbel.

[9]ALLIUM *Victorialis*.

*Victorialis, or Elliptical Garlick.*] Allium with elliptical, plane, cauline leaves, ſpear-ſhaped ſtamina longer than the corolla, and a round umbel.

All theſe ſpecies are of the bulbous rooted tribe; ſome have very large bulbs, others not bigger than peas: they are perennial in root, but annual in leaf and ſtalk.

They are all extremely hardy, will proſper in almoſt any expoſure and ſoil of a garden, and multiply exceedingly.

Moſt of the ſorts have a ſtrong ſcent like the common garlick.

The firſt ſort, *Common Garlick*, hath a large, round, white, bulbous root, compoſed of many ſmaller bulbs called cloves, each of which being planted, grow, and in one ſeaſon attain the ſize and ſtructure of the parent bulb; the leaves are cauline, or form a kind of ſtalk, which, in this ſpecies, ſeldom ſpindles, except when the ſame roots remain in the ground two or three years, when they run up and bear a flower, and ſmall bulbs at top.

This ſort merits culture in every garden for its roots for kitchen and other domeſtic uſes.

The *Rocambole* hath very ſmall bulbs, which grow in cluſters; the ſtalk generally ſpindles two or three feet high, bearing many ſmall bulbs at its ſummit, and theſe are commonly uſed inſtead of the root

With reſpect to the flowery kinds, the flower-ſtems riſe immediately from the root, grow erect, and attain different heights, from twelve to thirty inches, in ſome the leaves are radical, in others cauline, i. e. elevated with

with the ſtalk; ſome are broad like thoſe of a tulip, others long and narrow like a daffodil, and ſome taper and ruſh-like; and in all the ſorts the ſtems are terminated by a ſpatha or ſheath, from which is protruded an aggregate of many ſmall flowers, forming a ſort of umbel. The flowers ſingly are compoſed each of ſix petals, which, though ſeparately ſmall, many being collected into large heads, are very conſpicuous.

The *Allium Moly*, *Subhirſutum*, *Sphæroce-phalon*, *Roſeum*, and *Allium Flavum*, grow from twelve to fifteen or eighteen inches high, and their umbels continue a month in bloom.

The *Allium Magicum* and *Victorialis*, riſe about a yard in height, and produce large and very ornamental umbels.

They flower in May, June, and July, ripen plenty of ſeed, and in ſome many ſmall bulbs on the ſtalk and umbel.

*Propagation, &c.*

All the ſorts may be propagated with the utmoſt facility by off ſets of the root, and many of them by ſeed, and the ſmall bulbs on the ſtalk.

The Common Garlick is always propagated by the ſmall bulbs that compoſe the main root, which may readily be divided into many ſeparate cloves; theſe are to be planted in the ſpring, in beds four feet wide, in rows length ways ſix inches diſtance, four inches aſunder in each row, and two or three inches deep, planting them either with a blunt dibber, or draw drills, and place the cloves therein, and cover them with the earth.

Being thus planted, they will ſhoot up their leaves in a month or ſix weeks; and all the culture they require is occaſional ſmall hoeing to kill weeds.

In the end of July or beginning of Auguſt, the bulbs will be full grown, as will be diſcoverable by the yellow hue and withering of the leaves; then take them up, clean and dry them in the ſun, and tye or plait them in bunches to be hung up for uſe.

The Rocambole may be propagated either by the off-ſets of its roots, or by the cloves produced on the ſtalks, which ſhould be planted in autumn, by which, both the root and ſtalk bulbs will be conſiderably larger than if planted in ſpring.

Theſe are to be planted as directed for the garlick, and they will be fit for uſe in July or Auguſt.

It is however to be obſerved, the roots never acquire a large ſize.

All the flowering kinds propagate very faſt by off-ſets, which may be ſeparated any time after the decay of the flower, taking only the largeſt and plant them at once in the borders, and they will flower the following ſummer.

The propagation by ſeed is in a ſhady border in ſpring, and in autumn the plants will be fit to tranſplant.

ALLIUM-CEPA. The Onion.

We before noticed that the Onions are ſpecies of Allium, and under which genera we now range them; but to render the different ſpecies of that kind, and their culture more immediately conſpicuous and intelligible for practice, we judge it eligible to adopt this mode of ſeparate arrangement.

The characters, &c. are the ſame as the garlick already deſcribed.

The ſpecies are,

[1]ALLIUM-CEPA, *Cepa.*

*The Common Onion.*] Allium with a great bulbous root, fiſtular taper leaves, the flower-ſtalk naked, and with the lower part bellied.

*Varieties.*] Straſburg or Common oval Onion.——Spaniſh ſilver-ſkinned large flat Onion.——Spaniſh red-ſkinned large flat Onion.—Portugal great oval Onion.

[2]ALLIUM-CEPA *Major Perenne.*

*The Ciboule or Welſh Onion, or Major Perennial bulbleſs rooted Cepa.*

[3]ALLIUM-CEPA *Schænopraſum.*

*Cives, or Minor Perennial bulbleſs rooted Onion.*

[4]ALLIUM-CEPA *Aſcalonica.*

*The Eſcalot or Shallot, or Perennial bulbous Cepa*, with oblong bulbs growing in a cluſter.

The firſt ſpecies and varieties have large bulbous roots, the plants are biennial, i. e. being ſown, one year come up and arrive at perfection in the root, next year ſhoot up into ſtalk, flower, and ripen ſeed, when the ſtalks quickly die, and the individuals are at an end.

The ſecond and third ſpecies never form any bulbs at bottom, they are hardy and perennial, and may be continued many years by the roots. See their *Culture.*

The fourth ſort is bulbous rooted, perennial, and multiply exceedingly by off-ſets. Vide the *Culture.*

*Propagation and Culture; and firſt of the Common Onion.*

Of the four varieties of Common Onion, the Straſburgh is the beſt for general culture; it is a handſome bulb, generally aſſuming an oval

oval ſhape, is of firm growth, and keeps well for winter ſervice.

The Spaniſh Onions are large and flat, the white ſort is of mildeſt flavour. Both the varieties generally turn out very profitable crops, and none excells them for culinary purpoſes, but they rarely keep ſo well after Chriſtmas as the Straſburgh or oval Onion.

The Portugal Onion is a very large handſome bulb, of ſomewhat oval ſhape, although they rarely attain the ſize here as in Portugal, &c. as is obvious by thoſe imported annually from that kingdom by the orange merchants. If, however, ſeeds ſaved in Portugal are ſown here, the bulbs will arrive at a much larger ſize than from ſeeds ſaved in England, eſpecially if ſaved two or three years ſucceſſively, which will often be ſo far degenerated, that the bulbs become flat, and not larger than the common onions.

This ſort being very mild, is greatly eſteemed for ſauces, and other uſes in cookery.

All theſe ſorts are propagated by ſeed ſown annually; which, for the general crops, the proper ſeaſon is from about the twentieth of February until the latter end of March, obſerving however, in cold, wet, ſtubborn land, it is proper to defer ſowing entirely until towards the middle of the laſt named month. It is likewiſe to be remarked, that in caſes of omiſſion in ſowing at the times abovementioned, it may be performed in moiſt rich ſoils, with tolerable ſucceſs, any time before the fifteenth of April; but remembering that the crops of the February or March ſowing always bulb more freely, and acquire a much larger growth than thoſe ſown later.

The proper ſituation and ſoil for theſe crops ſhould be an open expoſure, and the land moderately light and rich; chuſing however a ſpot of the beſt mellow ground in the garden, with the addition, if poſſible, of a good coat of rotten dung, which ſhould be dug in, one ſpade deep, ſee TRENCHING, &c. obſerving to preſerve a level ſurface; and while it is freſh ſtirred let the ſeed be ſown, which is of particular importance. Do not however ſow it when the ſurface is ſo wet or moiſt as to c'og to the feet, or rake.

The proper quantity of ſeed is about an ounce to every rod or pole of ground, but if it is not required to have them thick for cullings, two ounces for three rods is ſufficient.

Be particularly careful to procure freſh ſeed; for of that which is more than one year old, not one in fifty will grow.

The ſeed may either be ſown all over the piece or plat of ground, and raked in; or the ground may firſt be divided into beds of four or five feet, allowing foot-wide alleys between; then ſow the ſeed with a regular ſpreading caſt, and immediately tread the ſurface over evenly; then pare the alleys an inch or two deep, and caſt the earth over the beds, and directly proceed to rake them length ways, keeping an even hand, and trim off all ſtones, &c. See SOWING SEED.

The ſowing them in beds is certainly the moſt eligible practice, when it is deſigned to draw or cull the young onions from time to time, for market or family ſervice, becauſe in ſuch caſes a perſon can ſtand in the alleys without treading at every turn upon the beds, which renders the ſurface hard, to the detriment of the crop, as well as unavoidably trampling upon the plants themſelves; and it is likewiſe very convenient to ſtand in the alleys to weed, thin, or hoe the crop.

It is a common practice in the general culture of onions to ſow them thick, to allow for culling or drawing out the ſuperabundant plants by degrees as they are wanted. We, however, adviſe to ſow a piece particularly for general culling, excluſive of the main crop, for by a daily thinning out the ſuperfluous plants, there is no avoiding treading upon, diſturbing, and looſening the remaining ones, and the plants thereby become of ſtinted growth.

Another very common practice is, the mixing of other crops, ſuch as leek, lettuce, radiſh, carrot, &c. with the crops in queſtion, a practice we declare againſt, as introducing confuſion in general, and obſtruction to the chief crop, without producing any conſiderable advantage; nothing therefore ſhould be admitted, except, if thought convenient, a thin ſprinkling of coſs lettuce.

In fifteen or twenty days after the ſeed is ſown, the plants will appear; and in a month or ſix weeks after that, they will be three or four inches high, and weeds will be numerous, when they ſhould be cleaned from weeds, and thinned to three or four inches diſtance. The weeding and thinning ſhould be began in due time, before the weeds branch and ſpread, which may either be performed by hand or ſmall hoeing; the latter is the moſt expeditious method, as one man may do as much as three, and is alſo the moſt beneficial to the plants, for by ſtirring the ground about them with the hoe, it will greatly facilitate

litate their growth, as will be obvious in a few days after the operation; a ſmall hoe two inches broad is the proper ſize; chuſe dry weather, cut up all weeds, and where the plants ſtand cloſe, cut them out to two or three inches diſtance; but if they are not wanted for culling, uſe a broader hoe, and cut them out to about four inches diſtance each way, having regard to leave the ſtrongeſt and moſt promiſing plants.

In a month after run over them again with the hoe, and cut up weeds, and any ſuperfluous plants that eſcaped you the firſt time; after this they will require no farther culture than pulling out ſtraggling weeds.

In July the plants will begin to ſwell greatly at bottom, and in Auguſt the bulbs will be fully grown.

Towards the middle of Auguſt, therefore, examine the crop in general; when the necks ſhrink and fall, and the leaves wither, it may be preſumed the bulbs are arrived at maturity, and are done growing, and ſhould be pulled up, cleaned, dried, and houſed for uſe: this ſhould be done in dry weather; at the ſame time hoe and rake a piece of the ground clean, and as you pull the onions, ſpread them thereon to dry and harden. Here let them lie about a fortnight, turning them every day or two, when, if the weather proves dry, they will be duly prepared for keeping, then take the firſt opportunity to houſe them before wet weather prevails. Let the bulbs be firſt diveſted of all adhering earth, looſe ſkins, and the groſſeſt parts of the leaves and neck, rejecting all infectious and bruiſed ones; and carry them into any dry upper room out of the damp, ſpreading them on the floor not more than a foot thick, but if room to lay them thinner, it will be an advantage.

Being now houſed, the cloſer the room is kept the better, obſerving to turn them over once in three weeks, and clear out ſuch as have any tendency to infection, which they would ſoon communicate to others in their neighbourhood, and it would become general.

*Obſervations.*] In the culture of onions it often happens that, through badneſs of ſeed, many are diſappointed of a crop, by waiting long in expectation of the plants riſing, till it has been too late to ſow again. In this caſe recourſe may be had to tranſplantation from other gardens, either from a neighbouring one, where there are ſuperfluous crops, or may purchaſe a bed, or ſuch part of one as is neceſſary from a market gardener; this ſhould be done in May, or early in June, and if poſſible in moiſt weather: having a ſpot of well-dunged ground prepared, take up the plants with good roots, and plant them in rows ſix inches diſtance, and four inches aſunder in each row, giving directly a hearty watering.

Repeat the waterings occaſionally for a week or fortnight, and the plants will grow freely, and you will not be diſappointed; they will form handſome bulbs.

Onions for pickling are in great requeſt. Thoſe proper for that purpoſe ſhould not be bigger than common round buttons; to procure which in due quantity, ſome ſeed ſhould be ſown late in a ſpot of light poor land; about the middle of April is the proper time: ſow it moderately thick, and the plants need not be thinned except they riſe in very thick cluſters. They will bulb in June and July, and be fit to take up in Auguſt.

Right pickling onions ſell well in the markets; thoſe that are cleaned and trimmed ready for the pickling tub fetch from eight to twelve ſhillings per buſhel.

In the ſpring many of the keeping onions will unavoidably grow as they lie in the houſe, theſe may be planted out in rows ſix inches diſtance, and will ſerve to draw up by way of eſcallions.

*Of the Autumn or Michaelmas Crop.*

This crop is generally ſown in Auguſt, and the plants ariſe before Michaelmas, ſtand the winter, and are intended principally for ſpring ſervice, to draw up young for ſallads, &c. and likewiſe, if the Straſburgh or any other variety of the Common Onion are ſown, they, if permitted to ſtand, will bulb to a tolerable ſize in June, and ſupply the kitchen or market as headed onions till thoſe of the ſpring crop are bulbed.

But as the Common Onion is liable to be cut off in ſevere winters, it is neceſſary always at the ſame time to ſow ſome beds of Welch Onions, which bid defiance to the moſt rigorous froſt. See their *Culture*.

We obſerved above, that Auguſt is the ſeaſon for ſowing theſe crops; it is to be remarked, that in warm rich land, from the fifteenth to the twenty-fifth, is the proper period; but in cold or poor ground, always ſow in the firſt or ſecond week of that month, obſerving to ſow them in beds four feet wide, with twelve inch alleys between; do not ſpare ſeed, and tread and rake it in as directed in the ſpring crop.

The plants will appear in a fortnight, and with them numerous weeds, to which early attention muſt be had to clear them out by hand before they begin to ſpread, but the plants of this crop are not now to be thinned.

In November and December however, if they ſtand very thick, ſome of the largeſt may be thinned out occaſionally for uſe.

*Of ſaving Seed of this Species.*

February is the proper time to plant onions for ſeed, though this is often done in October by thoſe that ſave great quantities for ſale.

For this purpoſe make choice of a due quantity of the largeſt and handſomeſt bulbs, rejecting all blemiſhed ones, and ſuch as have already made any effort to grow, and having made choice of a ſpot of ground well expoſed to the ſun, which being dug, proceed to plant the onions; ſtrain a line, and with a hoe or ſpade open three drills, twelve inches aſunder, and ſix deep, place the bulbs therein nine inches diſtance, and rake the earth over them; meaſure off two feet for an alley, and plant three more rows as above, and in that manner proceed to the end; the wide ſpaces of two feet is by way of alleys to go between to hoe and clear off weeds, as well as to ſtake and ſupport the ſtalks of the plants when neceſſary.

In June the flower ſtalks will be ſhot to their full height, and the flower heads will be formed at top, to ſecure which in erect poſition, drive ſome ſtout ſtakes in the ground along each row, at two yards diſtance, and from ſtake to ſtake faſten double lines of packthread, and if theſe are tied together in the intervals between the ſtems of each plant, it will effectually ſecure them.

About the latter end of Auguſt the ſeed will be ripe, which is very diſcoverable by the capſules opening, and the black colour of the ſeed; cut the heads in a dry day, and ſpread them upon cloths in the ſun, but remove them under cover at night; and in a week or fortnight beat or rub out the ſeed; clean it from the rubbiſh, and put it up in bags for uſe.

*Obſervation.*] Good onion ſeed is a very material article to be attended to: it is to be remarked that this ſeed never germinates freely after the firſt year, but notwithſtanding this, ſeeds-men are very apt to mix more than half old ſeed with their new, to the great loſs and diſappointment of many; to try its goodneſs, ſome, before they venture their general crop, ſow a little in a pot, and place it in a moderate hot-bed, or near a fire; but the moſt expeditious method is this, tye about a thimble-full of the ſeed looſely in a piece of linen rag, and put it into a veſſel of boiling water, ſuſpended by a thread; in ten or fifteen minutes pull it out, and if the ſeeds are good, they will in that ſhort ſpace of time be germinated or chipped, perhaps a quarter of an inch in length.

Leek and other ſeed of ſimilar nature may be tried by the ſame experiment.

*Culture of the ſecond Species, Ciboule, or Welch Onion.*

The *Ciboule* or *Welch Onion* is a perennial plant; this never forms any bulb at bottom, ſo merits culture only to draw as young green onions for ſallads, &c. in ſpring, but on account of its ſtrong temperament of taſte, is greatly inferior to thoſe of the Common Onion. However, as the plants being ſo extremely hardy as to ſurvive the ſevereſt winter, that although their blades are generally cut off, the roots remain ſound, and ſhoot forth with great vigour early in ſpring, and furniſh a ſeaſonable ſupply till May, when they generally run to ſeed, for which ſingular merit they demand general attention.

We noticed above of their being perennial; they are ſo in root, which encreaſe by off-ſets into great cluſters; but they are not to be propagated thereby for general uſe; their propagation is by ſeed, the ſame as the former ſorts.

Theſe are cultivated principally to ſtand the winter for ſpring ſervice. The ſeaſon for ſowing them is in Auguſt. See *Michaelmas Onions*.

The plants will appear in twelve or fifteen days, and toward Michaelmas let them be carefully hand-weeded.

It is peculiar to this ſpecies to loſe their tops in November or December, and remain diveſted thereof till towards Candlemas, when the roots ſhoot forth again; at this period it will be good culture to dig the alleys, and ſpread about an inch depth of the earth evenly over the ſurface of the beds; it will add vigour to the roots, the plants will riſe ſtrong, and all that part within the earth will be blanched white, which will be more agreeable to the eye, and the whole will be more tender and mild to eat, either alone or in ſallads.

If the ſowing of a Michaelmas crop has at any time been omitted, you may ſow ſome ſeed of this ſort toward the end of January; the plants will riſe in February, and being hardy,

hardy, will continue growing, and be fit to draw in April.

To ſave plenty of ſeed of this ſpecies, it is proper to retain ſome plants for ſtools. In the end of March put out a parcel of ſtrong young plants, nine inches diſtance, which will produce ſeed in Auguſt; let the roots remain, and in the following years will produce treble the quantity; but as they encreaſe into great bunches, the ſtools ſhould be removed and ſeparated every third year.

*Culture of the third Species, the Cives.*

This is the ſmalleſt of all the onion kind, it riſing but a few inches high; but its roots are perennial, and encreaſe conſiderably into cluſters, from which riſe large tufts of ſlender awl-ſhaped leaves, which are the only part uſed, the roots never forming any bulb, at leaſt not bigger than ſmall peas.

This little hardy plant merits a place in every garden: its cluſters of leaves riſe early in ſpring, which being of an agreeably mild temperature, is very proper as a ſallad ingredient; and the method of gathering it is to cut the leaves off near the ground, and a freſh ſupply is ſoon produced from the bottom.

It is eaſily encreaſed by dividing the roots in ſpring, and plant eight or ten together in holes ſix inches diſtance, and by autumn they will be multiplied into large bunches.

*Culture of the fourth Species, Eſcalot, or Shallot.*

This ſpecies of onion is bulbous-rooted, which encreaſe greatly by off-ſets, the largeſt of which are the proper parts of the plant for uſe.

The bulbs of this plant are oblong, irregular, and ſeldom grow large, becauſe they generally encreaſe into cluſters, that they cannot ſwell like roots that grow ſingly; from the root is produced many long, narrow, infirm leaves, coming up in ſpring, and wither in Auguſt, when the roots are full grown.

The propagation of this plant is by the ſmaller roots or off-ſets; theſe may be planted in autumn, or early in ſpring; November is the proper time for the autumn, and February for the ſpring plantation; thoſe of the former generally attain the largeſt ſize, particularly in light ſoils; they are to be planted in beds four feet wide, the off-ſets to be planted ſingly in holes ſix inches diſtance, and two or three deep.

All the culture the plants require is to be ſmall hoed occaſionally, to deſtroy weeds.

Towards the end of July, or beginning of Auguſt, the bulbs will have attained their full growth, as will be determined by the withering of the leaves; take them up in a dry day, and ſpread them in the ſun to harden, then clean and bunch the largeſt for uſe, and reſerve the ſmaller off-ſets for propagation.

ALLIUM-PORRUM, the Leek, being the third and laſt diviſion of the genus ALLIUM.

The general characters are the ſame as the Allium before deſcribed.

The ſpecies and varieties are,

ALLIUM PORRUM, *Porrum.*

*The Leek.*] Allium with an oblong tunicated root, plane cauline leaves, flowers gathered in cloſe heads, and triple-pointed ſtamina.

*Varieties.*] Broad leaved or London Leek.—Narrow leaved Leek——Striped leaved Leek.

Theſe plants may be deemed biennial; for although the roots often ſurvive after perfecting ſeeds, yet the plants always attain perfection the ſame year they are ſown, and next year they run up to ſtalk, and become unfit for uſe.

The ſeed-ſtalk of this does not belly like that of the onion.

The firſt of theſe three varieties is the ſort proper for general culture, which attains a large growth, the neck acquiring a thick ſubſtance, in length from ſix to nine or ten inches, dividing upward into many large, long, thick leaves, arranging themſelves fan faſhion.

The ſecond ſort runs up with a long thin neck, and narrow thin ſtraggling leaves, which, being a degenerate variety, do not merit culture.

The ſtriped leaved kind is retained for variety, which may be continued by ſuckers ariſing from the old roots.

*Propagation, Culture, &c.*

The Common Leek is raiſed annually from ſeed ſown in the ſpring; the proper time for ſowing the general crop for autumn and winter ſervice, is the ſame as adviſed for the onion, i. e. from the twentieth of February to the end of March; but for latter crops to ſtand for ſpring uſe, may ſow any time in April.

It is a common practice with many, out of a falſe notion of making the moſt of their ground, to ſow Leeks along with their crops of onions, which is what we would not recommend, having experienced it to be conſider-

ably the beſt culture to keep them ſeparate, though it is often practiſed by the market gardeners, when intending to cull out the onions from time to time for market, ſo that by a daily thinning they are often all cleared off by the end of July, and thoſe being gone, the ſame ground remains occupied by a crop of Leeks; but this cannot be practiſed to advantage in the main crops of onions that are to ſtand to grow to full ſize for keeping.

The beſt culture therefore we would recommend for the general crops of Leeks, is to ſow them pretty thick in a ſpot by themſelves, to be afterwards tranſplanted.

The ſame ſituation, ſoil, and method of ſowing, is to be obſerved as directed for the onion.

In June, July, and Auguſt, the plants will be of due ſize for tranſplanting: make choice of an open ſpot of the beſt ground, and if dunged it will be of much advantage, digging in the dung one ſpade deep; then draw a parcel of the largeſt Leeks, and trim their tops and the extreme parts of their fibres, and proceed to plant them by line and dibber in rows, which for the early crop ſhould be twelve inches diſtance, and eight inches a-part in each row, and for latter crops nine inches between the rows, and ſix the other way is ſufficient, putting them three or four inches in the ground, or nearly to the length of their necks, and directly let them be watered.

All the culture they require is to be kept clean from weeds, which may be done with the utmoſt facility, by applying a ſharp hoe in dry weather.

Leeks thus cultivated will be finer than thoſe that remain where ſown; their necks, which is the principal eſculent part, will be much longer, and all that part within the earth will be finely whitened, and rendered mild and tender, which is a deſirable property in the Leek.

The general ſeaſon of Leeks for uſe, is from September until May, when they ſhoot up their ſtalks for flower and ſeed.

To ſave Leek ſeed, mark a quantity of the fineſt plants, and in February tranſplant them into a ſheltered ſunny border, under a wall, pale, hedge, or reed fence; this is neceſſary, becauſe the ſeeds ripen late in autumn, and unleſs aſſiſted by ſuch ſituation and ſhelter, they do not ripen freely in England.

It would be of particular advantage to plant ſome in a row cloſe along under the fence, at ten or twelve inches diſtance in the row.

They will ſhoot up their ſtalks conſiderably in May, and in June will attain two or three feet ſtature, when they ſhould be ſupported, and continued cloſe to the fence. In July the flowers will be protruded from their ſheath at the ſummit of each ſtalk, and form a large globular head or aggregate; and in September the ſeeds will begin to ripen. When that is effected, cut the heads with part of the ſtalk, tye them in bunches by threes, and hang them acroſs lines in a dry airy apartment, two or three months, when the ſeed will be hardened, and the capſules will readily break by threſhing or rubbing, to diſcharge it from the cells.

ALOE, the *Aloe Africana*, or African Aloes.

The number of Aloes is very conſiderable, many of them of ſingular beauty and curioſity; they are univerſally perennial, ſucculent, and evergreen, chiefly natives of Africa, and conſequently require ſhelter here in winter, though the major part need only that of a green-houſe.

Former botaniſts, before Linnæus, having conjoined this genera and the Agave or American Aloe, on account of their conformity of habit, are now ranged as diſtinct genera, principally from this circumſtance, that in the former the ſeed-bud or germen is placed within the corolla; in the latter, below it. There is alſo obvious differences in the growth of the plants; in the Agave the centre leaves are cloſely infolded, incloſing the flower-ſtem, and never flower but once, and that not till they have attained a great age, then periſh, ſee AGAVE. In the Aloe the leaves are open quite to the centre, and the flower-ſtem is protruded from one ſide thereof, and the plants ſurvive and continue flowering annually.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX none. COROLLA, one long tubular petal, ſix-parted, and ſpreading at the brim. STAMINA, ſix filaments, and ſimple antheræ. PISTILLUM, a germen placed within the corolla, a ſingle ſtyle, and trifid ſtigma. PERICARPIUM, the germen ſucceeds to an oblong capſule of three cells, furniſhed with angular ſeeds.

The ſpecies are,

1 ALOE *Mitriformes.*

*Mitre ſhaped Aloe.*] Aloe with an erect ſtem, elevating, broad, erect, ſpinous edged, converging

verging leaves, and drooping flowers, in a nearly cylindrical corymbus.

[2]ALOE *Arboreſcens.*

*Tree, or Sword Aloe.*] Aloe with an erect ſhrubby ſtem, elevating, long, narrow, reflexed, indented, ſpinous leaves, embracing the ſtem with their baſe, and pyramidal ſpike of red flowers.

[3]ALOE *Ferox.*

*Ferox, or Fierce-like Aloe.*] Aloe with a ſhrubby ſtem, ſupporting broad, dark green leaves, embracing it with their baſe, and having every ſide armed with robuſt ſpines.

[4]ALOE *Plicatilis.*

*Plaited, or Fan Aloe.*] Aloe with a ſhrubby ſtem, ſupporting heads of long, compreſſed, ſword-ſhaped, unarmed leaves, ſtanding two ways, with the edges lapping over one another, and looſe ſpikes of reddiſh flowers.

[5]ALOE *Vera.*

*True Succotorine Aloe.*] Aloe with an erect ſtem, long, narrow, ſpinous edged, ſucculent leaves, collected into diverging heads, and a long ſpike of red flowers.

[6]ALOE *Diſticha.*

*Horizontal, or Soap Aloe.*] Aloe with a ſhort ſtalk, broad, ſpotted, ſpinous edged leaves, ſpreading horizontally every way, embracing the ſtem with their baſe, and red flowers in umbels.

[7]ALOE *Variegata.*

*Variegated, or Partridge-breaſt Aloe.*] Dwarf Aloe with triangular, ſhort, thick, variegated, white and green, ſlightly-ſawed leaves, turning back at the ends, and ranged three ways; and flowers in looſe cluſters.

[8]ALOE *Linguiforme.*

*Tongue-ſhaped Aloe.*] Dwarf Aloe with ſhort tongue-ſhaped, cloſe growing, ſlightly ſpotted leaves, and drooping flowers.

*Varieties.*] Tongue Aloe with longer and deeply ſpotted leaves.—Tongue Aloe with broad, faintly ſpotted leaves, ranged cloſely together.

[9]ALOE *Verrucoſa.*

*Warted Tongue Aloe.*] Dwarf Aloe with long tongue-ſhaped leaves, concave above, and carinated below, ranged two ways, cloſely warted or ſtudded with white tubercles, and drooping red flowers.

*Varieties.*] Warted keel-ſhaped Aloe, having broad, thick, keel-ſhaped leaves, and ſpread every way.—Warted coral Aloe, having broad, ſhort, thick leaves, ſtanding two ways, and coral coloured flower-ſtalks.

[10]ALOE *Margaritifera.*

*Pearl Aloe.*] Dwarf Aloe with cluſtered, thick, ſhort, triangular-pointed leaves, the points long and turn up, cloſely covered with pearly tubercles, and flowers having two lips, the upper one erect, the under one ſpreading.

*Varieties.*] Smaller Pearl Aloe, having very ſhort leaves.—Leaſt Pearl Aloe, having extremely ſhort thick leaves.

[11]ALOE *Arachnoides.*

*Cobweb Aloe.*] Dwarf Aloe with flat growing, ſhort, plane, fleſhy, triangular-pointed leaves, the edges cloſely ſet with numerous hair-like ſpines.

*Variety.*] Cobweb Aloe, with cylindrical, baſed, triangular-pointed leaves.

[12]ALOE *Retuſa.*

*Retuſe-leaved or Cuſhion Aloe.*] Dwarf Aloe with ſhort, thick, ſwelling leaves, having triangular compreſſed ends; and trigonous flowers, having two lips, the under one rolled back.

[13]ALOE *Humilis.*

*Humble, or Hedge-hog Aloe.*] Aloe with ſhort, erect, broad-baſed, taper leaves, triangular at the ends, and both ſurfaces cloſely ſet with ſpines.

[14]ALOE *Spiralis.*

*Spiral upright Aloe.*] Aloe with a ſhort ſtem, cloſely ſet round with oval, ſharp-pointed, imbricated leaves; and oval crenated flowers, without foot-ſtalks.

*Varieties.*] Pentangular Upright Spiral Aloe, having the leaves ranged five ways.—Triangular Upright Spiral Aloe, having triangular leaves, and theſe ſtanding three ways, like a triangle.

[15]ALOE *Uvaria.*

*Flag-leaved, or Iris Uvaria Aloe.*] Aloe with very long, narrow, triangular leaves from the root; and a cluſtered ſpike of cloſe-fitting, reflexed, imbricated, yellow flowers.

All theſe plants obtain different ſtatures, from three inches to three yards, and are of various ſingular growths, producing leaves of many different ſizes, ſhapes, and determinations. Some riſe with erect ſtems, ſupporting leaves two or three feet in length at top; others are compoſed entirely of dwarf leaves, ſtanding in a cluſter on the crown of the root, of which, ſome grow flat to the earth, others grow erect, ſome ſpread every way, others range in two, three, and five different directions, and various other poſitions, that in the whole they afford a great ſource of variety.

The roots of all the ſorts are fibrous and perennial.

The

The firſt ſix ſpecies riſe with an erect ſtem, elevating the leaves; the others are chiefly of low dwarfiſh growth, with the leaves riſing immediately from the root. The ſtalks and leaves are alſo perennial, at leaſt the ſame leaves are of ſeveral years duration, and continue encreaſing in ſize, attaining, in different ſpecies, from three inches to three feet in length, and from one to ſix inches broad at the baſe, and end in a point, and thoſe of all the ſorts are thick, ſucculent, and of fleſhy ſubſtance. The flower-ſtems in all the ſorts riſe among the leaves, and attain from eighteen inches to three feet in height, the flowers ſtanding in a ſpike at the top, each flower formed of one tubular petal, the colour chiefly red, and ſome are of a white and greeniſh hue, appearing at different times, but moſtly in autumn.

All the ſorts flower annually in their native ſoil, and moſt of them do the ſame here, eſpecially if they are wintered in a ſtove.

The *Mitre Aloe* is ſo termed from the figure of its leaves; the ſtem is erect, and by degrees attain four or five feet ſtature, ſurrounded by broad, erect, dark green leaves, eighteen inches long; thoſe at top form a head, and converge towards their extremity in form of a mitre.

The *Aloe Arboreſcens*, *Aloe Ferox*, and *Aloe Plicatilis*, riſe each with a ſtrong naked ſtem, which, in many years growth, attains eight or ten feet in height, and ſupports the leaves at top, which attain two feet or more in length.

The *Succotorine Aloe* advances with an erect ſtem, gradually riſing three or four feet high, ſupporting the leaves in heads at top, grow two feet long, and diverge every way.

The *Soap Aloe* riſes with a ſhort ſtem, eighteen inches or two feet high, adorned on every ſide with horizontal leaves, of a dark green colour, ſpotted with white, ſomewhat reſembling the colour of ſoft ſoap, whence the plant derives the name.

The *Aloe Variegata*, *Aloe Linguiforme*, *Aloe Verrucoſa*, and *Aloe Margaritifera*, are plants of humble growth, have no ſtalk, the leaves ſtanding in a cluſter on the crown of the root, and growing from ſix to twelve inches high.

The *Cobweb Aloe* riſes but a few inches high, the leaves ſit cloſe to the earth.

The *Arachnoides* and *Aloe Humilis* rarely riſe more than five or ſix inches high; the leaves ſtand in a cluſter on the head of the root, and grow nearly erect.

The *Aloe Spiralis* riſes ten or twelve inches high, having a ſhort erect ſtem, cloſely ſet with ſhort thick leaves on every ſide, from bottom to top, placed one above another.

The *Aloe Uvaria* hath great ſingularity; the leaves riſe in a great cluſter from the crown of the root, very narrow, erect, and three or four feet long; the flower-ſtalk riſes in the centre a yard or more in height, ſupporting a vaſt cluſtered ſpike of yellow flowers.

This is the hardieſt of all the ſpecies, as it will ſometimes ſucceed in a warm border.

*Culture, Propagation, &c.*

All theſe plants are natives of Africa, and other warm countries, and in this climate require the ſhelter of a green-houſe, from the end of September until the beginning of June, ſo muſt always be retained in pots. It is however to be remarked, that although theſe plants may be wintered very well in a green-houſe, yet if they are indulged with the temperature of the ſtove during that ſeaſon, they more certainly produce flowers annually.

With reſpect to the general culture of all theſe plants, they may be placed in the full air from the beginning of June until the middle of September; but obſerving, if immoderate rains prevail, they ſhould have occaſional ſhelter, otherwiſe, they being very ſucculent, it would rot them. In ſummer, when the weather is hot and dry, they will need moderate watering twice a week, but in winter, in a green-houſe, once in two or three weeks is ſufficient.

The plants in general ſhould be ſhifted into freſh earth every year or two, and they will occaſionally require larger pots, either of which operations may be performed any time in ſummer. See SHIFTING PLANTS.

When any of the leaves are decayed, broken, or bruiſed, they ſhould be cut off cloſe.

The propagation of the greater part of theſe plants is effected by the off-ſets or ſuckers, which moſt of the ſorts yield abundantly; and thoſe that furniſh none may be encreaſed by cutting off their leaves, which, with the aid of a hot-bed, emit roots freely.

The time of year for either of the above methods of propagation, is from the middle of June until the end of July.

The method is as follows.

In the firſt place prepare a compoſt of light ſandy loam from a paſture, uſing the top ſpit, and almoſt an equal portion of ſea ſand; or in default of which, road ſoil; and if theſe are previouſly mixed and expoſed in the full air and ſun ſeveral months, it will be an advantage:

vantage: then, at the ſeaſon above-mentioned, ſlip off the ſuckers from the parent plant, and obſerve if their baſes are very moiſt; lay them in a dry ſhady place three or four days, till they become dry and firm; this done, get the pots, which ſhould be forty-eights, or ſixty-twos for the ſmall ſorts, and fill them with the compoſt; plant one ſucker in each pot, and directly give water, and place the pots in a green-houſe, or in a common frame, to be ſcreened occaſionally from the ſun and violent rains, and in three or four weeks they will be firmly rooted; and may then be fully expoſed, but defending them however from exceſſive wet, which is apt to rot theſe ſucculent plants.

The propagation by leaves is neceſſary for ſuch that afford no ſuckers. In June cut off ſome freſh under-leaves, and lay them on a ſhelf a few days, till their ſucculent baſes are healed over, then plant them in ſmall pots as above, and plunge them in a hot-bed, giving occaſional ſhade, water, and freſh air.

The *Aloe Uvaria*, producing plenty of ſeeds, it may be propagated thereby at pleaſure, which may be ſown in autumn in pots, and ſheltered occaſionally in a frame till ſpring, when the plants will appear; and in July plant them ſingly in pots, to be moved to ſhelter in winter; for although the plants, when they have obtained a year's growth, will ſucceed in a warm border, it is nevertheleſs proper to retain ſome in pots, to be protected from froſt.

The following are alſo of this genus.

[1]ALOE *Barbadenſis*.

*Barbadoes, or Hepatic Aloe.*] Aloe with broad, thick, erect, ſubulate, indented, ſea-green leaves, and a looſe ſpike of hanging yellow flowers.

[2]ALOE *Glauca*.

*Glaucous, or Sea-green Aloe.*] Aloe with a ſhort ſtalk, the leaves embrace it, and ſtand two ways.

*Variety.*] Short, ſpreading leaved, glaucous Aloe.

The firſt ſort requires the conſtant ſhelter of a ſtove in winter.

The ſubſtance known among druggiſts by the name of Aloes, is the inſpiſſated juice of the *Aloe Vera* and *Barbadenſis*; the fineſt is that of the Succotorine Aloe, and is greatly uſed in medicine; that of the other is commonly called *Hepatic Aloes*, and is uſed chiefly for horſes.

The above juice is drawn from the plants by expreſſion or inciſion; that of the Succotorine Aloe is yellow, bitter, and ſmells like myrrh.

ALTHÆA. Marſh-Mallow.

The plants are herbaceous perennials, of hardy growth, obtaining an annual ſtature of four or five feet, adorned on every ſide with large, roundiſh, velvety leaves, and mallow-like flowers.

Claſs and order, *Monadelphia Polyandria*, many ſtamina united in one body.

*Characters*] CALIX, two monophyllous cups, the outer one nine, and the inner five-parted at the brims. COROLLA, five heart-ſhaped petals expanding above. STAMINA, numerous filaments united in a pillar. PISTILLUM, an orbicular germen, many pointed ſtyle, and many ſtigma. PERICARPIUM, the calix becomes a round depreſſed capſule of many cells, containing kidney-ſhaped ſeeds.

The ſpecies are,

[1]ALTHÆA *Officinalis*.

*Common officinal Marſh-Mallow.*] Althæa with angulated, pointed, and ſharply indented downy leaves.

*Varieties.*] Common Marſh-Mallow with roundiſh angulated leaves.—Common Marſh-Mallow with deeply ſinuated leaves.

ALTHÆA *Cannabina*.

*Hemp-leaved Hungarian Marſh-Mallow.*] Althæa with the lower leaves palmated, thoſe above more deeply fingered.

The firſt ſpecies and varieties ſucceed in any common ſoil and expoſure; the ſecond requires a dry ſoil.

The roots of all the ſorts are fibrous and perennial, from which are produced ſtrong, erect, tall growing ſtems, which, in the common ſorts, are herbaceous and annual; in the ſecond ſomewhat woody, and of two or three years duration.

The ſtems of each ſort riſe four or five feet high, emitting ſide branches, adorned with ſimple leaves, in alternate arrangement, which, in the common ſorts, are velvety; in the other a little hairy, and from the angles of the branches and leaves proceed the flowers, which are reddiſh, compoſed each of five petals, ſhaped like thoſe of the Common Mallow, but ſmaller, appearing in June and July, and ſeeds ripen in autumn.

All the varieties of the firſt grow wild in marſhy places in many parts of Britain; the ſecond in Hungary.

The Common Marſh-Mallows are eſteemed principally as medical plants, but are alſo admitted

mitted in gardens by way of variety; the ſecond ſort is alſo retained in the gardens of the curious.

*Culture.*

All the ſorts may be propagated plentifully by ſeed ſown in the ſpring, and the common ſorts alſo by parting the roots at that ſeaſon, or rather in autumn, when the ſtems decay, obſerving, if they are to be cultivated for medical uſes, to plant them in beds fifteen or eighteen inches diſtance.

ALYSSUM, *Alyſſon*, or Madwort.

This genus retains many ſpecies, moſt of which may be deemed ſhrubby, herbaceous perennials, of the ornamental flowery kind, which attain from one to two feet ſtature, adorned with hoary leaves, and flowers in cluſters at the ends of all the branches.

Claſs and order, *Tetradynamia Siliculoſa.*

*Characters.*] CALIX is four-leaved, and deciduous. COROLLA, four petals diſpoſed like a croſs. STAMINA, two ſhort and four long filaments, having broad antheræ. PISTILLUM, an oval germen, ſingle ſtyle, and blunt ſtigma. PERICARPIUM, a round compreſſed pod, containing flat ſeeds.

There are many ſpecies, thoſe of moſt note are,

[1]ALYSSUM *Saxatile.*

*Common yellow Rock Alyſſon.*] Alyſſum with a ſhrubby branching ſtalk, ſpear-ſhaped, entire, waved, ſoft leaves; and yellow flowers in panicles.

[2]ALYSSUM *Halimifolium.*

*Sea Purſlane-leaved Alyſſon.*] Alyſſum with ſhrubby trailing ſtalks, narrow, ſpear-ſhaped, pointed, entire leaves; and white flowers in cluſters.

[3]ALYSSUM *Montanum.*

*Mountain dark yellow Alyſſon.*] Alyſſum with ſhrubby trailing ſtalks, and diffuſed branches, ſpear-ſhaped, obtuſe, hoary leaves; and dark yellow flowers in cluſters.

[4]ALYSSUM *Deltoideum.*

*Deltoid-leaved Alyſſon.*] Alyſſum with ſhrubby trailing ſtalks, lanceolate-deltoid leaves; and violet coloured flowers in looſe ſpikes.

[5]ALYSSUM *Spinoſum.*

*Prickly Alyſſon.*] Alyſſum with erect branches, armed with ſpines; and white flowers diſpoſed in cluſters.

[6]ALYSSUM *Incanum.*

*Hoary erect Alyſſon.*] Alyſſum with erect ſtalks, ſpear-ſhaped, hoary, entire leaves; and white flowers in a corymbus.

[7]ALYSSUM *Creticum.*

*Cretan yellow Alyſſon.*] Alyſſum with an erect herbaceous ſtalk; hoary, ſpear-ſhaped, entire leaves, and ſwollen ſeed pods; bright yellow flowers in cluſters.

All theſe ſpecies are natives of France, Spain, Portugal, &c. but ſucceed here in any common ſoil of a garden, where moiſture is not copious.

They have ſomewhat ſhrubby ſucculent ſtalks and branches, growing from one to two feet high, which, in the firſt ſix ſpecies, become woody and abiding; in the other, they being more herbaceous and ſucculent, ſeldom continue above two or three years: all the ſorts are adorned with hoary leaves, and flowers produced in cluſters at the end of all the ſhoots; each flower is compoſed of four croſs-ſhaped petals, which, though ſmall, being numerous on each plant, are very conſpicuous, appearing at different times in ſummer, and ſucceeded by ripe ſeed in autumn.

The *Common yellow Alyſſon* produces erect ſtalks a foot high, dividing into many low ſpreading branches, each of which is terminated by looſe ſpikes of flowers in May, and continue a month.

The *Alyſſum Halimifolium, Montanum*, and *Deltoideum*, ſpread their branches each way upon the ſurface of the earth, having every ſhoot terminated by the flowers, which, in the former, continue five or ſix months.

The *Alyſſum Spinoſum*, *Incanum*, and *Creticum*, are of erect growth, the two former attaining two feet ſtature, the latter about eighteen inches, branching out upward, adorned with cluſters of flowers, proceeding from the extremity of each branch, appearing in June, July, and Auguſt.

*Culture, Propagation, &c.*

As all theſe plants in their native climate prevail chiefly in rocky, dry, gravelly, and rubbiſhy places, the ſame ſhould be imitated here in their culture; let them therefore occupy places in dry warm borders, &c. becauſe in rich moiſt ſoils they become very ſucculent, and the froſt affects them in winter.

All the ſpecies may be propagated by ſeed, and moſt of them alſo by ſlips and cuttings of their ſhoots.

The ſeed ſhould be ſown in April, in a bed of dry light earth, and the plants will be ready for tranſplantation early in autumn. The propagation by cuttings, &c. may be effected

fected in April, May, and June, in a ſhady border, aſſiſted by occaſional waterings.

AMARANTHUS, Flower-Gentle, Love-lies-bleeding, Prince's-Feather, &c.

The number of Amaranthus is very great; they are univerſally herbaceous and annual, ſome of which are curious ornamental plants, of ſingular beauty and elegance, attaining in ſtature from three to ſeven feet; ſome grow pyramidally, others branch out tree-faſhion, &c.

Claſs and order, *Monoecia Pentandria.*

*Characters.*] CALIX, three or five coloured permanent leaves. COROLLA none, the leaves of the calix ſupply its place, and the flowers are monoecious. STAMINA, five filaments in each male flower. PISTILLUM, in each female flower an oval germen, three ſtyles, and three ſimple ſtigma. PERICARPIUM, an oval capſule of one cell and one ſeed.

The ſpecies that demand attention are,

[1]AMARANTHUS *Tricolor.*

*The Tricolor, or Three-coloured Amaranthus.*] Amaranthus with an erect ſtem; oval, ſpear-ſhaped, three-coloured leaves; and roundiſh heads of flowers embracing the ſtem.

[2]AMARANTHUS *Melancholicus.*

*Bicolor, or Two-coloured Amaranthus.*] Amaranthus with an erect ſtalk; ſpear-ſhaped, pointed, two-coloured leaves; and flowers collected in a roundiſh head, ſitting cloſe to the ſtem.

[3]AMARANTHUS *Maximus.*

*Tree Amaranthus.*] Amaranthus with an erect tree-like ſtem, branching horizontally, and large, hanging almoſt cylindrical ſpikes.

[4]AMARANTHUS *Caudatus.*

*Trailing ſpiked Amaranthus, or Loves-lies-bleeding.*] Amaranthus with an erect ſtem, branching horizontally, and very long, hanging, and trailing cylindrical ſpikes.

[5]AMARANTHUS *Sanguineus.*

*Bloody-leaved Amaranthus.*] Amaranthus with erect ſtalks and branches, oblong oval leaves, compound erect ſpikes, and the lateral ones ſpreading.

[6]AMARANTHUS *Hypocondriacus.*

*Dark purple Amaranthus, or Prince's Feather.*] Amaranthus with erect ſtalks and branches; oval pointed leaves, and cluſtered erect ſpikes.

The firſt five ſpecies are tender exotic annuals, that require to be raiſed in a hot-bed, and the ſixth is an annual of hardy growth. See their *Culture.*

Theſe plants riſe with erect ſtems, from two to ſeven feet high, riſing annually in the ſpring from ſeed; attain their full height, flowering ſtate, and general perfection, in July; continue in beauty three months, perfect ſeeds in September and October, and in November the whole individual periſhes.

The flowers of all the ſpecies are devoid of petals or flower-leaves; the leaves of the calix or cup, which are of a purple colour, and permanent, ſupply their place.

The *Amaranthus Tricolor* and *Bicolor* grow four, five, or ſix feet high, and aſſume a beautiful pyramidal growth, adorned with large and elegantly variegated leaves, which, in the former ſort, are green, yellow, and bright red; in the latter, a dark purple, and deep crimſon, very conſpicuous, and appear with great luſtre, and are the principal ornament of the plants.

The flowers of both theſe ſpecies ſit cloſe to the ſtalks in ſmall round heads, and make no appearance.

The *Tree Amaranthus* is an annual of ſtately growth, and grand appearance; it riſes with an erect ſubſtantial ſtem, ſeven feet high, at every ten or twelve inches ſending forth many horizontal branches, ornamented with luxuriant, rough, green leaves; and large, long, roundiſh, purple flower-ſpikes, proceeding from the extremity of every ſhoot, and hanging looſely downward.

The *Amaranthus Caudatus* obtains three or four feet ſtature, branching out every way horizontally, adorned with large pale green leaves, and very long, pendulous, purple ſpikes, at the joints and ends of all the branches and ſhoots, ſome in cluſters, others advance ſingly a yard in length, hanging down like a tail, and often trail on the ground, hence the plant obtained the old name, Love-lies-bleeding.

The *Bloody Amaranthus* riſes a yard high, the ſtem and branches erect, terminated by large cluſters of ſhort croſs-placed ſpikes, with an upright ſpike terminating each cluſter; and the whole plant is of a blood-purple colour.

The *Amaranthus Hypochondriacus* grows three feet high, dividing into many erect branches, adorned below with dark liver-coloured leaves, and terminated by large cluſtered, erect, purple ſpikes; this, being an old reſident in almoſt every garden we admit it in the collection for variety: it is ſo hardy, that from the ſcattered or ſelf-ſown ſeeds many plants continue riſing annually.

*Uſe in Gardens, &c.*

The firſt four ſpecies, when raiſed in their ultimate perfection, are great ornaments to

the pleaſure garden, and the *Tricolor* and *Bicolor* are the greateſt beauties of the annual tribe. Theſe two ſpecies are always cultivated in pots, and diſpoſed with cock's-combs, &c. to adorn court-yards, and other conſpicuous compartments contiguous to the main habitation, grand walks, lawns, and ornamental garden buildings. The other four ſorts are choice furniture for large open borders, and other compartments that verge principal walks, and home lawns, &c.

*Propagation.*

The propagation of all the ſpecies is by ſeed annually in the ſpring, aſſiſted by artificial heat.

The two firſt ſorts particularly require the aid of different hot-beds, and conſtant ſhelter of frames and glaſſes, until the latter end of June, otherwiſe the plants cannot be obtained of due ſtature, which, if leſs than three or four feet, they make no figure.

The general ſeaſon for ſowing theſe two ſpecies is March, but to obtain them in early perfection, and forward enough to perfect ſeeds, it is adviſeable to ſow them in the firſt or ſecond week in that month.

To raiſe theſe two curious annuals in their fulleſt luſtre, it is neceſſary to be furniſhed with new hot dung, ſufficient for two or three different hot-beds, together with as many different ſized garden frames and glaſs lights. See ANNUAL PLANTS. The firſt of theſe hot-beds ſhould be made for a one-light frame, and covered with light rich earth, four inches deep, in which ſow the ſeed, ſee ANNUAL PLANTS, and raiſe the plants an inch or two high, admitting air in the day, and cover the glaſs at night with a garden-mat; then, when the plants have obtained the above ſize, prepare a ſecond hot-bed, and prick the plants therein four inches diſtance; give moderate waterings, and occaſional ſhade from the ſun, till they have taken root, and admit freſh air daily by raiſing one end of the light, and continue the night-covering, and when the plants have grown here a month, they will meet and require more room, when a third and final hot-bed, of larger dimenſions, ſhould be made; place a frame thereon, and lay in four or five inches thickneſs of earth; then take up the plants with balls of earth about their roots, and plant each in a twenty-four ſized pot; give water, and plunge the pots immediately in the earth of the bed, managing as above; obſerving, that according as the plants reach the glaſſes, the frame muſt be as often raiſed or deepened, ſee ANNUAL PLANTS, continuing the lights always on, and tilt them at one end daily to admit air, giving water every day or two, and by the end of June the plants will have nearly attained their full ſtature, and the weather will be ſettled, when they ſhould be brought forth and placed where they are to remain, obſerving to ſupport each with a handſome ſtrait ſtake.

The plants are to be continued in the pots, and their principal culture, after being placed abroad, is to ſupply them duly with water, which they will need every day in dry hot weather.

For more particulars on their culture, ſee ANNUAL PLANTS.

To obtain good ſeed of theſe two ſorts, place ſome plants in a deep frame in September, to have occaſional ſhelter of the glaſſes from wet and cold.

The propagation of the third, fourth, and fifth ſorts, is alſo to be effected by the aid of artificial heat; the time to ſow them is towards the latter end of March, or beginning of April. Theſe three ſorts however, being hardier, do not require the aid of but one or two moderate hot-beds; that is, to be ſown and raiſed in one till they are two or three inches high, then tranſplanted into a new one, which will forward them greatly, and in which to remain until the beginning of June, then taken up with balls of earth to their roots, and planted where it is deſigned they ſhall remain to flower. Some may be planted in pots, but the principal part in the border, &c. giving water directly, and repeat it occaſionally for a week, till they have taken root.

The ſixth ſort will riſe freely in the common ground; but to obtain it in more early and greater perfection, manage it as the laſt three ſorts.

The ſeed of the laſt four ſorts ripen towards the latter end of September, when ſome of the largeſt ſpikes ſhould be gathered and ſpread in the ſun, in a dry airy room, for a fortnight.

AMARANTHUS, the Cock's-Comb. See CELOSIA.

AMARANTHUS, the Globe. See GOMPHRENA.

AMARYLLIS, Lily-Daffodil.

The plants are of the bulbous rooted tribe, and produce large liliaceous-like flowers, of extreme beauty and elegance.

Claſs

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, a ſpatha or ſheath. COROLLA, ſix oblong ſpear-ſhaped petals STAMINA, ſix filaments, with incumbent antheræ. PISTILLUM, a round germen, ſingle ſtyle, having a trigonous ſtigma. PERICARPIUM, an oval capſule of three cells, encloſing round ſeeds.

The ſpecies of note are,

[1]AMARYLLIS *Lutea.*

*Yellow Autumnal Amaryllis.*] Amaryllis with one equal flower from each ſheath, having declinated ſtamina.

[2]AMARYLLIS *Atamuſco.*

*Atamuſco Amaryllis.*] Amaryllis with one equal flower, and declinated ſtyle.

[3]AMARYLLIS *Sarnienſis.*

*Guernſey Amaryllis, or Lily.*] Amaryllis with many flowers in each ſcabbard, having revolute petals, and erect ſtamina and ſtyle.

[4]AMARYLLIS *Regina.*

*Bella-donna Amaryllis, or Lily.*] Amaryllis with many bell-ſhaped equal flowers in each ſheath, and drooping ſtamina and ſtyle.

[5]AMARYLLIS *Bella-donna.*

*Mexican Bella-donna Amaryllis.*] Amaryllis with two or three bell-ſhaped equal flowers from each ſcabbard, and declinated ſtamina and ſtyle.

[6]AMARYLLIS *Zeylanica.*

*Ceylon Amaryllis.*] Amaryllis with a taper two-edged ſtem, many bell-ſhaped equal flowers in each ſcabbard.

[7]AMARYLLIS *Formoſiſſima.*

*Moſt handſome Amaryllis, or Jacobæan Lily.*] Amaryllis with one large, irregular, nodding flower, and the ſtamina and ſtyle drooping.

[8]AMARYLLIS *Orientalis.*

*Oriental Amaryllis, or Brunſwigia.*] Amaryllis with numerous irregular flowers in each ſheath, and tongue-ſhaped leaves.

All theſe plants produce very pretty flowers; ſome are of ſingular beauty, and merit places in every curious garden, where there are conveniences for their culture. The two firſt are hardy, the third and fourth require ſhelter from froſt; the other four need the aid of a ſtove.

*General Deſcription.*

The roots are univerſally bulbous, moſtly very large, and commonly oblong.

The flower-ſtem riſes annually from the root, in moſt ſorts naked and unattended by leaves, and attain different heights, from three inches to two feet, and at the termination or ſummit of each ſtem, is produced the flower-bud, which is a ſheath or ſcabbard, that burſts and protrudes the flower or flowers, which are large, and compoſed each of ſix oblong petals, of the liliaceous form, appearing chiefly in autumn, and when they fade the leaves come up, which are generally long and narrow, ſome large and flaggy, and which, together with the main bulbs and off-ſets, continue growing until May or June, when the leaves decay, and is the time to remove or tranſplant the roots, and ſeparate the off-ſets for propagation.

The *Yellow Autumnal Amaryllis* attains but three or four inches in height, ſeveral ſtems riſing in ſucceſſion, each ſupporting one large yellow flower, in September and October.

The *Amaryllis Atamuſco* ſends up one ſtem, ſix inches high, elevating one large beautiful flower, carnation-coloured, changing almoſt white, appearing in ſummer or autumn.

The *Guernſey Amaryllis* is one of the fineſt flowers that can be ſeen. The ſtem riſes a foot and half high, terminated by an oblong ſcabbard, from which burſts forth the cluſter of flowers; the colour a bright ſhining red, ſpangled with golden ſpecks, and a deep red vein running along the middle of all the petals. It flowers in October, and continues a month in full luſtre.

The *Amaryllis Regina* ſends up an erect firm ſtem, two feet in height, ſupporting an umbel of ſix or eight very large reddiſh purple flowers, in October.

The *Mexican Amaryllis* riſes a foot high, crowned by two, three, or four large flame-coloured flowers, in March or April.

The *Ceylon Amaryllis* demands eſteem both for its beauty and delightful fragrance. The ſtem attains two feet in height, ſurmounted by ſix or eight ſnowy white flowers, having all the petals beautifully ſtreaked with lines of purple.

The *Jacobæan Amaryllis* is a flower of ſuperior beauty, and ſingularity of form. The flower-ſtalk obtains fifteen inches ſtature, crowned by the flower, there being only one, which is very large; the colour a beautiful ſcarlet, with crimſon filaments, and yellow antheræ; the petals are irregular, and their determination is curious, three of which droop, two ſtand horizontally, and one erect; the whole nods on one ſide of the ſtalk. The plant flowers in ſpring, autumn, or winter; and it is peculiar to the ſpecies, that after having ſent up a flower-ſtem on one ſide of the bulb, it frequently ſends up one or two

more, in ſucceſſive order, from the other ſides.

The *Oriental Amaryllis* ſends up a robuſt ſtem a foot high, terminated by a large ſwelling ſcabbard, which protrudes a conſiderable ſpherical cluſter of fine red flowers, each of which have five of its petals turned inward, and the ſixth ſtands outward. It flowers late in autumn.

*Culture, Propagation, &c.*

The bulbs of all theſe plants may be purchaſed at moſt of the nurſeries, and planted in Auguſt and September.

The two firſt ſorts may be planted in any dry warm border, eſpecially the firſt, where they will flower annually; the other being ſomewhat impatient of ſevere froſt, it is alſo neceſſary to plant ſome in pots, to have occaſional ſhelter in winter.

The *Guernſey Lily* requires protection from exceſſive wet and froſt, ſo ſhould be planted in pots to be moved to occaſional ſhelter during their bloom, and from the rigour of winter.

Great numbers of theſe bulbs are imported hither annually from the Iſle of Guernſey, for ſale; they generally arrive in July, which if procured and planted before the middle of Auguſt, ſome of the large roots will probably flower the following October. The proper ſized pots wherein to plant theſe bulbs are twenty-fours, which fill with rich, light, ſandy earth, plant one root in each pot three inches deep, and place the pots where they may be ſcreened from the mid-day ſun during the hot weather, giving occaſional moderate waterings, and about the middle of September, when the flower-bud will begin to make its appearance, remove them to the full ſun, to remain till their flowers begin to expand, then place them to have occaſional protection from rains and boiſterous winds, either in a green-houſe, garden-frame, or any airy room.

When the flower fades, remove them into a garden-frame for the winter, to have occaſional ſhelter of the glaſſes in times of violent rain, froſt, ſnow, &c.

As it is peculiar to this ſpecies to flower ſomewhat reluctantly, inaſmuch, that probably not five roots in twenty will perform that office the ſame ſeaſon; therefore, permit the bulbs to remain unremoved three years, managing them as above, and they will afford a more conſiderable bloom the ſucceeding autumns. It is however always eligible culture to tranſplant the bulbs once in the above period into freſh earth, and ſeparate the off-ſets, which plant either in pots, or in a bed of light dry ſoil, giving occaſional ſhelter in winter, and in three years they will attain a flowering ſtate, when they are to be treated as already directed.

The *Bella-Donna Amaryllis* is tolerably hardy, and will ſucceed in a warm dry border, with occaſional ſhelter from froſt. It is however adviſeable to plant ſome alſo in pots, and manage them as directed for the Guernſey Lily. If it is indulged with a ſtove, it generally flowers with greater luſtre.

The *Mexican*, *Ceylon*, *Jacobæan*, and *Oriental Amaryllis*, are of tender temperature, which, though they may be preſerved through the winter in a warm green houſe, they rarely flower, unleſs the pots are plunged in a good hot-bed, under frames and glaſſes, towards the time of their reſpective ſeaſons of flowering. All theſe ſorts, however, ſucceed beſt in a ſtove, and where there are ſuch conveniences, it is eligible culture to indulge the plants with that temperament of heat, when they will not fail to produce their beautiful flowers annually, and the Jacobæan Amaryllis often two or three times in that period of time.

All the ſorts are propagated by the off-ſets, or ſmaller bulbs, that ariſe annually from the ſides of the main roots, which ſhould be tranſplanted when their leaves decay, and the off-ſets ſeparated for propagation, and planted by themſelves, and in two or three years they will attain a due ſize for flowering, when they are to be managed as above directed.

AMBROSIA.

The plants are chiefly herbaceous. There are ſix ſpecies, of which two only merit conſideration.

Claſs and order, *Monoecia Pentandria.*

*Characters.*] CALIX, a monophyllous common cup. COROLLA, many male monopetalous florets in the ſame calix, and female apetalous flowers in different cups. STAMINA, five filaments in each male floret. PISTILLUM, in each female flower a germen, and ſtyle having two long ſtigma. PERICARPIUM, a leafy capſule of one cell, and one ſeed.

The ſpecies of moſt note are,

[1]AMBROSIA *Elatior.*

*Taller, Mugwort-leaved, Annual Ambroſia.*] Ambroſia with doubly-pinnatifid leaves, and branches terminated by paniculated ſpikes.

[2]AMBROSIA

1 AMBROSIA *Arboreſcens.*

*Tree-like Peruvian Ambroſia.*] Ambroſia with a ſhrubby perennial ſtem, pinnatifid, winged-like, hairy leaves, and the branches terminated by ſimple ſpikes.

The firſt ſort is a hardy annual, that obtains three or four feet ſtature, and is of branching growth, producing cluſtered ſpikes at the end of every branch.

The *Tree Ambroſia* is a ſhrubby perennial, which grows eight or ten feet high, branching out upwards; the whole becomes woody, and of ſeveral years duration, and flowers annually; the flowers collected in ſimple ſpikes, proceeding from the end of all the branches.

The ſpikes in both ſorts are amentaceous, and ſupport both male and female flowers.

Both theſe ſpecies are exotics; the firſt is of Virginia, &c. and the ſecond comes from Peru. The former ſucceeds in the common ground, and may be admitted in the collection of hardy annuals, in decorating the flower-borders; and the ſecond is tender, ſo muſt be potted and placed among the green-houſe exotics.

Their propagation may be effected by ſeed in a moderate hot-bed or warm border, in March; and the Tree Ambroſia may alſo be raiſed with great facility by cuttings, which grow freely in a ſhady border in May or June.

AMENTACEOUS FLOWERS, from *Amentum*, having that ſpecies of calix or cup called *Amentum*. All Amentaceous Flowers are aggregate, and conſiſt of a great number of minute flowers, and ſquamæ or chaffy ſcales, mixed alternately, and diſperſed along a ſlender thread-like receptacle, which hang looſely down like a tail, and from the reſemblance of ſome ſorts to a cat's tail, has obtained the name of catkin. See AMENTUM.

The following genera are of the Amentaceous kind.

Birch, beech, hazel, horn-beam, walnut, oak; pine, poplar, juniper, cypreſs, arbor-vitæ, willow, &c.

AMENTUM, Catkin; defined to be a compoſition of ſcaly calix and flowers, diſpoſed along a thread-like receptacle. The ſquamæ or ſcales that form the Amentum, mix alternately with the flowers, and reſemble the chaff in an ear of corn.

AMOMUM, Ginger.

The plants are herbaceous exotics, of the Eaſt and Weſt Indies, and are cultivated here in ſtoves for curioſity.

Claſs and order, *Monandria Monogynia.*

*Characters.*] CALIX is indented into three parts. COROLLA is monopetalous, tubular, and three-parted at the brim, and a nectarium in its boſom. STAMINA, one filament, and thick antheræ. PISTILLUM, a round germen under the receptacle, a ſingle ſtyle, having a hairy ſtigma. PERICARPIUM, a trigonous capſule, having ſeveral ſeeds.

The ſpecies are four, thoſe that merit notice are,

1 AMOMUM *Zinziber.*

*Common Ginger.*] Amomum with naked flower-ſtems, and an oval ſpike of flowers.

A 2 MOMUM *Zerumbet.*

*Zerumbet, or Broad-leaved wild Ginger.*] Amomum with naked flower-ſtems, and oblong blunt ſpikes.

The plants grow three or four feet high, are perennial in root, but the ſtalks and leaves riſe in ſpring, and periſh in autumn.

The roots are thick, fleſhy, jointed, and ſpread each way in the earth.

The ſtalks are reed-like, and grow erect; thoſe of the firſt riſe two feet and half high, the ſecond above a yard; many ſuch ſtalks often proceed from the ſame root, ornamented with leaves placed alternate, their baſes embracing the ſtalks; thoſe of the firſt are long and narrow, and in the ſecond they are oblong and broader. From one ſide of the ſtalks ariſe the flower-ſtems immediately from the root, each terminated by the flowers, which are arranged in cloſe, ſcaly ſpikes; thoſe of the Ginger are blue, the other white.

Both ſorts flower in autumn, and in November the whole decays to the ground.

The dried roots of the firſt ſpecies is that well known aromatic called Ginger, being much uſed for kitchen and medical purpoſes.

Their propagation is effected by parting the roots early in ſpring, before they ſhoot forth new ſtalks, planting the off-ſets in pots of light rich earth, and plunging them in the bark-bed in the ſtove, giving occaſional waterings, which, after they begin to ſhoot, they will need twice a week.

AMORPHA, Baſtard Indigo.

There is but one ſpecies, which is a hardy, deciduous, flowering ſhrub, of tall growth, with long winged leaves, and butterfly-ſhaped flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, tubuloſe, and five-parted at the margin. Co-

ROLLA

ROLLA is papilionaceous, but the wings and keel are wanting. STAMINA, ten filaments connected at their base, and simple antheræ. PISTILLUM, a roundish germen, single style, and stigma. PERICARPIUM, a moon-shaped leguminose pod, containing two kidney-shaped seeds.

The species is,

AMORPHA *Fruticosa.*

*Shrub Amorpha.*] Amorpha with false acacia leaves, and purple flowers.

This shrub rises ten or twelve feet high, advancing generally with several stems, which branch out irregularly, and produce large soft shoots, ornamented with long winged leaves, composed of many pair of lobes, and numerous small papilionaceous, dark purple flowers, in long spikes, proceeding from the extremity of the young shoots in summer, but it rarely ripens seed in this country.

It is a native of America, where, of its young shoots, was formerly prepared an inferior sort of Indigo.

For uses in gardening, this shrub may be employed to good advantage in composing large shrubberies.

The propagation of this plant is by seed, and layers of the young branches. The seed is procured from America, and sown in a bed of common earth in spring; the laying may be performed in that season, or in autumn, and by autumn following the layers will be fit to transplant.

AMYGDALUS, The Almond-Tree, which comprehends also the Peach and Nectarine.

According to the Linnæan system of botany, all the sorts of Peaches and Nectarines are retained as species of *Amygdalus*, under which genus we shall also range them; but to render the whole more intelligible for common practice in their cultivation, shall proceed in three divisions, the first division to contain those commonly considered as Almonds; second, the Peach-Tree, *Amygdalus-Persica*; and third, the Nectarine, *Amygdalus-Nucipersica*.

Class and order, *Icosandria Monogynia.*

*Characters.*] CALIX is monophyllous, tubular, and obtusely five-parted above. COROLLA, five oval concave petals inserted into the cup. STAMINA, twenty, or more filaments, and as many antheræ. PISTILLUM, a roundish germen, simple style, having a round stigma. PERICARPIUM, the germen becomes a large oval downy pulpy fruit, enclosing a hard nut or stone, containing one seed or kernel.

*First Division.*

Of the Almond kind, the following are the principal species and varieties.

[1]AMYGDALUS *Communis.*

*Common Almond Tree.*[ Almond-Tree with foot-stalked, sawed leaves, and reddish flowers, in pairs, having the petals emarginated.

*Varieties of this are,*] Common Almond with bitter kernels.—Common Almond with a tender shell, and bitter kernels.—Common Almond with sweet kernels.

The following are also supposed to be only varieties of the Common Almond.

[2]AMYGDALUS *Sativa.*

*Manured, or White flowered Almond-Tree.*] Almond-Tree with linear-lanceolate, sharp-pointed, crenated leaves, and white flowers.

[3]AMYGDALUS *Dulcis.*

*Sweet, Tender-shelled, Jordan Almond.*] Almond-Tree with petiolate, short, broad, crenated leaves, and pale red flowers no longer than the calix.

[4]AMYGDALUS *Orientalis.*

*Eastern Silvery-leaved Almond.*] Almond-Tree with spear-shaped, silvery, short, foot-stalked leaves, continuing great part of the year.

[5]AMYGDALUS *Nana.*

*Dwarf Almond.*] Almond with low slender stems and branches, and petiolate leaves, narrowed at the base, and sawed on the margin.

*Varieties of this are,*] Dwarf Almond with single red flowers.—Dwarf Almond with double red flowers.

All these species and respective varieties are deciduous, and of hardy temperature, that prosper in any common soil of a garden. They are considered principally as plants of ornament, for the beauty of their early flowers, which surround all the young branches and shoots in great numbers, and are extremely conspicuous; they come out before the leaves, composed each of five small petals, and are universally hermaphrodite, appearing early in spring, and which, in the *Amygdalus Communis*, and *Sativus*, are frequently succeeded by plenty of ripe fruit in autumn, which, in all the varieties, obtains an oval form, and large size, is downy, and has a thick tough pulp, enclosing a large oblong nut or stone, containing a large kernel, which is the Almond, and the only esculent part of the fruit, many of which are extremely sweet and palatable.

The

The tree kinds flower early in March, and the fruit ripens in September; and the dwarf ſorts flower the end of March, and beginning of April.

The *Amygdalus Communis* and varieties obtain about fifteen or twenty feet in height, and divides low into many ſpreading branches, which ſhoot ſtrongly, but in time forms regular ſpreading heads, adorned in ſpring with innumerable flowers, ariſing cloſely all along the ſides of the young branches and ſhoots, and in a manner covers them, continuing a fortnight or three weeks in full luſtre, and make a fine appearance; and when they fade, the leaves, which are long and narrow, come out, and the fruit take their growth.

The ſeveral varieties of this ſpecies are frequently obtained from the ſeed or kernels of the ſame tree, of either ſort; that with the ſweet kernels is often cultivated as a fruit-tree, for the ſake of the ſaid kernels, and when once obtained, the ſort is continued with certainty by inoculation. See their *Culture*.

The *Amygdalus Sativa* attains twelve or fifteen feet in height, is a moderate ſhooter, and the flowers ſmall; but being white, numerous, and tolerably conſpicuous, they form an agreeable contraſt with the common ſorts; but the bloſſoms being impatient of cutting froſts, they are rarely ſucceeded by much fruit, unleſs the trees have a ſheltered ſituation, or are trained againſt a ſouth wall.

The *Amygdalus Dulcis*, and *Orientalis*, riſe twelve or fifteen feet high, they ſhoot moderately, and produce very ſmall flowers, but rarely any fruit in England.

The two varieties of Dwarf Almond are low ſhrubs, that ſeldom exceed three or four feet in height; the ſtems are ſlender, and ſend forth numerous feeble branches near the ground, and the ſingle flowered ſort ſend up many ſuckers from the root. Both theſe ſhrubs have all their young branches cloſely adorned in ſpring with flowers, which, being of a fine pale red colour, very numerous, and ſhowy, make a beautiful appearance for about a fortnight, and are ſome of the greateſt ornaments of the ſpring.

The ſingle ſort flowers the end of March, and the double kind early in April, each continuing about a fortnight.

*Uſe in Gardens, &c.*

For uſes in gardening, theſe trees are eſteemed chiefly for the beauty of their flowers; but ſome of the tree kinds alſo demand attention as fruit-trees, and being of moderate growth, they may with propriety be admitted in gardens of any extent.

Thoſe that have the greateſt claim to eſteem, are the Common Almond, White flowering Almond, and the two varieties of the *Amygdalus Nana*. Of the two former, a few ſtandard trees diſpoſed alternately in ſhrubberies, or any ornamental plantation, have a fine effect in the ſpring ſeaſon, and are particularly ornamental on the boundaries of graſs lawns, contiguous to the manſion-houſe. Some trees dropped ſingly in different parts of large pleaſure grounds, will appear to great advantage during their bloom; and after the flower is paſt, the progreſs of the growth of the fruit of the two former ſorts affords amuſement to the curious.

Sometimes curious perſons train a few of the Common and White Almond, as dwarfs, or half ſtandards, againſt walls, or in eſpaliers, to obtain larger, forwarder, and better flavoured fruit, managing them as peach-trees.

The two ſorts of Dwarf Almonds, being ſhrubs of great beauty during their bloom, are proper furniture for the moſt conſpicuous compartments of ſhrubberies, and ſhould occupy places near the front, with ſhrubs of loweſt growth.

The other two ſpecies are alſo cultivated in ſome curious gardens for variety, eſpecially the Jordan Almond.

*Propagation, &c.*

The Common Almond and varieties may be propagated either by ſowing the ſtones of the fruit, or by budding them upon plumb, or almond ſtocks.

With reſpect to theſe two methods of propagation, thoſe that are budded ſooner form full and regular heads, and they likewiſe ſooner attain a ſtate of flowering and producing fruit; and beſides, if it is intended to continue the Sweet Kernelled, or any other particular ſort, it can only be done with certainty by inoculation; as when raiſed from ſeed they vary, and all the varieties often riſe from the fruit of the ſame tree. The inoculation is performed in July, in the uſual method, and may be budded either for dwarfs, half or full ſtandards; ſee INOCULATION. The firſt ſhoot from the bud is to be ſhortened in ſpring to four or five eyes, that it may put out lateral ſhoots to form a regular head, and in two or three years after they may be tranſplanted, either for bearing fruit, or for the purpoſes of ornament.

The

The ſecond, third, and fourth ſorts are alſo commonly propagated by inoculation, managing them as above.

To raiſe theſe trees from the ſtones, they ſhould be planted in autumn, i. e. October or November; chuſe thoſe of the ſame year's growth, and drill them in three inches deep, in a bed of light earth, the plants will appear in ſpring, and in autumn or ſpring following, tranſplant them in rows in the nurſery, where you may train them either for ſtandards, half ſtandards, or dwarfs, according to your fancy. See STANDARDS and DWARF-TREES.

If it is intended to bud any of them, either with Almonds or Peaches, they will be fit for that operation for dwarfs, ſome the firſt, and all of them the ſecond ſummer after tranſplanting; but for ſtandards they ſhould have three years growth, to be trained with proper ſtems. See INOCULATION and GRAFTING.

The two dwarf ſorts are alſo ſometimes propagated by budding upon plumb or Almond ſtocks; they may alſo be raiſed with great facility by ſuckers from the roots, which the ſingle kind particularly yield in great plenty; or, in default of which, both ſorts may alſo be raiſed expeditiouſly by layers.

*Second Diviſion.*

AMYGDALUS-PERSICA, the Peach-Tree, being the ſecond diviſion of the genus *Amygdalus*. See AMYGDALUS.

Claſs, order, and characters, the ſame as the Amygdalus.

The varieties of Peaches are very great, and by continuing to raiſe them from the ſeed or kernel, they may be multiplied indefinitely. It is to be obſerved, however, that notwithſtanding the number of varieties that may be obtained that way, it is probable not one in twenty is poſſeſſed of the proper qualities, as is obvious by the cultivated ſorts now known in England; for moſt of the eminent nurſery-men retain no more than from twenty to thirty ſorts in their catalogues, which they ſell as real good peaches. Some indeed extend them to forty or fifty, but among which there are many of very indifferent qualities, and not worth the ſpace they occupy; and ſince it is not more expence to cultivate the beſt than the more indifferent ones, the firſt only deſerve our regard; and as all the ſorts require to be trained againſt walls, the expence of building them is very conſiderable, and a good aſpected wall is too valuable to be filled with any but the capital ſorts. See WALLS, &c.

Theſe fruit are divided into two claſſes, i. e. Peaches and Pavies; the former are diſtinguiſhable by the fleſh or pulp readily quitting the ſtone, that of the latter firmly adheres thereto.

Botaniſts allow only one diſtinct ſpecies of Peach-Trees, all the different ſorts of fruit are varieties of one another, ſo that the trees of all the varieties bear the particular marks of the original ſpecies; which is,

AMYGDALUS-PERSICA, *Perſica.*

*The Peach-Tree.*] Amygdalus with ſawed leaves, and ſolitary flowers, ſitting cloſe to the ſides of the branches.

Varieties of the fruit are,

[1]*Early White Nutmeg Peach.*] A very ſmall oblong whitiſh fruit; ripe middle of July.

[2]*Early Red Nutmeg Peach.*] A ſmall, roundiſh, bright red fruit; ripe end of July.

[3]*Anne Peach.*] A ſmall, round, yellowiſh white fruit, faintly tinged with red on the ſunny ſide; ripe early in Auguſt.

[4]*Small Mignon Peach.*] A ſmalliſh round fruit, red on the ſunny ſide; ripe towards the middle of Auguſt.

[5]*Great Mignon Peach.*] A large round fruit, ſwelling on one ſide, and beautifully ſpotted with red next the ſun; ripe about the middle of Auguſt.

[6]*Early Purple Peach.*] A large, round, purpliſh red fruit; ripe middle of Auguſt.

[7]*Late Purple Peach.*] A fine large, round, dark red, or purple fruit; ripe middle of September.

[8]*White Magdalen Peach.*] A middle ſized, round, whitiſh fruit, one ſide deeply furrowed; ripe early in Auguſt.

[9]*Red Magdalen Peach.*] A beautiful large, round, red fruit; ripe end of Auguſt.

[10]*Early Newington Peach.*] A middle-ſized roundiſh fruit, elegantly red on the ſunny ſide; ripe in Auguſt.

[11]*Old late Newington Peach.*] A fine large round fruit, beautifully red next the ſun; ripe middle of September.

[12]*Montauban Peach.*] A middle-ſized roundiſh fruit, cleft on one ſide, and almoſt wholly of a purple-red colour; ripe towards the end of Auguſt.

[13]*Belle Chevreuſe Peach.*] A middle-ſized beautiful red fruit, of an oblong figure; ripe end of Auguſt.

[14]*Nobleſſe Peach.*] A very large roundiſh fruit, finely marbled with a purpliſh red; ripe beginning of September.

[15]*Yellow Alberge Peach.*] A middle-ſized, ſome-

ſomewhat longiſh, yellow-fleſhed fruit; ripe about the middle of Auguſt.

[16]*Belle Garde Peach.*] A fine, large, roundiſh fruit, almoſt wholly of a deep purple colour; ripe beginning of September.

[17]*Chancellor Peach.*] A large, ſomewhat oblong, bright red fruit; ripe end of Auguſt and September.

[18]*La Teton de Venus, or Breaſt of Venus Peach.*] A pretty large, ſomewhat longiſh fruit, deeply divided on one ſide, both diviſions ſwelling and rounded like a woman's breaſt, and of a pale red colour on the ſunny ſide; ripe towards the end of September.

[19]*Roſſana Peach.*] A middle-ſized, ſomewhat oval fruit, purple next the ſun; ripe early in September.

[20]*Perſique Peach.*] A fine large, roundiſh, and ſomewhat oblong fruit, terminated at top by a ſmall nipple, having the ſunny ſide red, the other pale green; ripe early in October.

[21]*Admirable Peach.*] A very large, round fruit, beautifully adorned with red next the ſun; ripe beginning or middle of September.

[22]*Rambouillet Peach.*] A large, longiſh, deeply-furrowed fruit, the ſunny ſide beautifully reddened, the other yellow; ripe towards the end of September.

[23]*La Royale, or Royal Peach.*] A large, round, almoſt wholly red fruit, but deeply reddened next the ſun; ripe end of September.

[24]*Bourdine Peach.*] A large, round, very fine fruit, bright red on the ſunny ſide; ripe beginning or middle of September.

[25]*Bloody Peach.*] A middle-ſized, deep red fruit next the ſun, and its whole pulp of a blood red colour; ripens late in October.

[26]*Nivette Peach.*] A very fine, large, longiſh, deep purple fruit next the ſun; ripe middle of September.

[27]*Portugal Peach.*] A large, round, even Peach, generally ſpotted, and the ſunny ſide elegantly reddened; ripe towards the end of September.

[28]*Royal George Peach.*] A middle-ſized, round Peach, furrowed on one ſide, of a deep red next the ſun, the other part white, ſpotted with red; ripe early in September.

[29]*Violet Peach.*] A middle-ſized, roundiſh, oval, violet-coloured Peach; ripe towards the middle of September.

[30]*Catharine Peach.*] A beautiful, very large, round Peach, the ſunny ſide wholly of a fine bright red, the other ſide white; ripens in October.

[31]*Monſtrous Pavie of Pomponne.*] An amazingly large and beautiful Peach, the ſhape round, and often meaſures twelve or fourteen inches in circumference; the ſide next the ſun is deeply reddened, and the other aſſumes a pale fleſh colour; ripe about the end of October.

[32]*Cambray Peach.*] A middle-ſized, longiſh, pale-coloured Peach; ripe in October.

[33]*Sion Peach.*] A large, handſome, round Peach, reddiſh on the ſunny ſide, the other ſide whitiſh; ripe end of September.

[34]*Narbonne Peach.*] A very large Peach, almoſt wholly of a greeniſh colour; ripe in October.

The above thirty-four varieties of Peaches are the principal ſorts of that univerſally admired fruit, known in Great Britain; and the name here annexed to each variety, is that by which they are generally known to all the nurſerymen, who cultivate the trees for ſale, to ſupply noblemen and gentlemen's gardens.

Many of the above varieties approach ſo near to one another in ſize, ſhape, and colour, that it is ſometimes difficult to determine their difference without the ſtricteſt attention.

We do not pretend to recommend all theſe varieties as real good Peaches, but for the ſake of thoſe who have large extent of walling, have collected all the principal ſorts to view, with ſhort deſcriptions of their ſizes, ſhapes, colours, and times of ripening, which it is preſumed will convey ſome idea of the reſpective varieties to the unexperienced, and help to direct him in the choice of the ſorts.

The ſorts that have the greateſt claim to eſteem, as the beſt and moſt beautiful, both in regard to ſize, ſhape, colour, flavour, and the beſt bearers, are the following.

The Anne Peach, Small Mignon, Great Mignon, Red Magdalen, Belle Garde, Belle Chevreuſe, Montauban, Admirable, Early Newington, Late Newington, Bourdine, Nivette, La Royale, Purple, Teton de Venus, Catharine, and Great Pavie of Pomponne; the latter chiefly for its prodigious ſize and beauty, and, as a pickle, it ſurpaſſes all the other ſorts.

The two Nutmeg Peaches, though of ſmall ſize and indifferent flavour, eſpecially the white ſort, they, on account of their early perfection, ſhould alſo be allowed a place in the collection.

The Bloody Peach merits a place more for ſingularity, than for the quality of the fruit.

The two Newington Peaches, Portugal, Catharine, and Monſtrous Pavie, may be deemed of the Pavie tribe, their fleſh adhering cloſely to the ſtone. The Old Newington and Catharine are eſteemed two of the moſt valuable Peaches that are cultivated in England.

Peach trees in general will grow fifteen or twenty feet high, if they have full ſcope; and if trained for ſtandards, and permitted to take their natural growth, they form regular heads, but they do not ripen their fruit well on ſtandards in this country, they being natives of a much warmer climate; ſo that, to effect the ripening of their fruit perfectly, they require the ſhelter of a warm wall, to which their branches ſhould be regularly trained.

The trees in general flower early in ſpring; the flowers come out before the leaves, appearing chiefly on the ſhoots of laſt year, ariſing ſome ſingly, others in pairs, all along the ſides of the ſhoot, to which they ſit cloſe; they are formed each of five ſmall petals, and many ſtamina in the middle, with a ſmall round germen, which becomes the Peach.

*Of their Propagation.*

The general propagation of Peach-trees is effected by budding them upon plum ſtocks.

But all the fine varieties of theſe fruit were originally obtained from the ſeed or kernel, and more new varieties may be gained by that means; but as we formerly obſerved the proceſs is ſomewhat tedious, and often terminates in but trifling ſucceſs, in reſpect to the quality of the fruit ſo obtained; for if you plant the ſtones of the fineſt ſorts, it is a thouſand to one, if, out of a great number, you obtain one like the originals, and but few that have any real merit, ſo greatly do theſe, and indeed all other fruits, vary from the ſeed. However, for the ſake of experiment, there are many who have curioſity and patience enough to undertake the acquiſition of new varieties by the above methods, and think themſelves amply rewarded if they gain one or two new ſorts that poſſeſs good qualities in reſpect to ſize, form, colour, and flavour.

The method of planting the ſtones for that purpoſe, is, they ſhould be planted in autumn, in drills two or three inches deep, and in ſpring following they will come up, and after having one ſummer's growth, they ſhould, in autumn or ſpring following, be tranſplanted in rows in the nurſery, and in a year or two after may be planted againſt any ſpare wall, pales, or reed fence, and trained as other Peach-trees; and when they have ſhown fruit, thoſe of merit ſhould be planted where they are to remain, which you may propagate or encreaſe by budding, as hereafter directed.

The only method of propagation, however, to continue, with certainty, the approved or any acquired ſorts of Peaches, is by budding, i. e. inoculation; ſince, by inoculating the bud of a tree of any of the kinds, in the ſtem or ſtock of any ſort of Peach, Almond, or Plum, the bud unites with the ſaid ſtock, the head of which being cut off, the bud ſhoots forth, branches out, and becomes a Peach tree, which will produce fruit in ſize, ſhape, colour, and flavour, exactly the ſame as that of the parent tree from whence the bud was taken, and by which means you may multiply any of the ſorts of Peaches, and other fruit trees at pleaſure, and with certainty, ſee INOCULATION; and beſides, trees thus raiſed, much ſooner attain a bearing ſtate than thoſe from the kernels.

Peaches, as above hinted, may be budded upon three or four different ſtocks, *viz.* upon thoſe raiſed from their own kernels, upon the almond, apricot, and plum. See STOCKS.

There is however but one ſort of ſtock proper for general uſe whereon to bud Peaches, which is that of the plum; the Peach, the almond, and apricot ſtocks, are often attacked by the gum, and communicate it to the trees juſt as they arrive at a ſtate of full bearing, and quickly go off; whereas, the plum ſtock being in every reſpect hardier, and better ſuited to different ſoils, Peaches budded upon them are generally healthful, and of long duration; obſerving, however, that experience has proved them to be the moſt proſperous and durable on one particular ſort, which is that of the true muſcle plum.

The propagation or raiſing ſtocks from the varieties of plums indifferently, as alſo of Peaches, almonds, and apricots, may with great eaſe be effected by ſowing the ſtones of the fruit in autumn, in drills two inches deep, and they will riſe freely the ſpring following; and in October they may be tranſplanted in rows two feet and half diſtance, and in the two following ſummers, thoſe that are intended to form dwarfs, may be inoculated with Peach-buds.

But in reſpect to the real muſcle plum ſtock, this cannot be obtained in its true ſtate from the ſtones, for they vary ſo greatly when raiſed from ſeed, that not one in a hundred

hundred will prove of that ſort; therefore, the only method to obtain the true muſcle kind is either by layers in autumn, or by ſuckers that are ſent up from the roots of Peach or plum-trees, that are known to be worked upon that ſort of plum. Theſe ſhould be collected in October or November; chuſe thoſe that are about the ſize of a large gooſe-quill; cut off any knots of old wood that adhere to their roots, and trim off all ſide-branches, and plant them in lines two feet and half diſtance, and in the following ſummer ſome will be fit to bud for dwarfs.

The proper ſized ſtocks to bud upon to form dwarfs, ſhould be about half an inch thick.

But if intended to form half or full ſtandards, the ſtocks, before they are budded, muſt be permitted to form ſtems an inch thick at bottom, and four, five, or ſix feet in height. See STOCKS, NURSERY, INOCULATION, &c.

The ſeaſon for budding them is Auguſt, though ſome perform that work in June and July; but when budded too early, the buds are apt to ſhoot the ſame year, which ſhoots, being weakly, are either killed in winter, or, if they eſcape the froſt, they never make great progreſs; therefore, from about the 25th of July to the 25th of Auguſt is the proper period for that operation, and the buds will remain dormant till ſpring, when they will ſhoot forth with vigour.

The method of performing the operation of budding, and every thing relating thereto for thoſe and other trees, is fully explained under that article. See INOCULATION.

We ſhall therefore only obſerve, that as Peach-trees require to be trained againſt walls, &c. they ſhould be budded principally to form dwarfs, that their branches may at firſt come out low, ſo as they may by degrees be trained to occupy every part of the wall, from bottom to top; the ſtocks ſhould therefore be budded within five or ſix inches of the bottom, but where there are high walls to furniſh, it is neceſſary alſo to raiſe half-ſtandards and ſtandards, to occupy the upper part, while the dwarfs are gradually advancing to cover the whole; the ſtocks, to conſtitute ſuch ſtandards, ſhould for half ſtandards be budded at the height of three or four feet, and for full ſtandards at that of five or ſix, or they may be budded near the ground, and the firſt ſhoot from the bud trained to the above heights to form a ſtem.

Obſerve to inſert only one bud in each ſtock, the heads of which are to remain on entire until ſpring.

In March following, the heads of all the ſtocks are to be cut off ſloping, juſt above the place of inſertion of the bud.

Soon after this the buds will ſhoot forth, each will produce one ſtrong erect ſhoot, which, by autumn, will probably attain three or four feet in height, and the trees have then acquired their firſt ſtate of formation, which, in October or November, ſhould be tranſplanted in the places where they are finally to remain; and in the ſpring after that they muſt be headed down to a few eyes, to procure laterals near the place of inoculation, to give the tree its ſuitable form for the wall, and in two or three years they will bear fruit. See *Planting the Trees*, *Heading Down*, *&c.*

*Of the Situation, Aſpect, and proper Soil for theſe Trees.*

With reſpect to ſituation and expoſure, the Peach-tree being originally a native of warm climates, is, in ſome reſpects, tender, and will not proſper, at leaſt not bear well, in an open ſituation; ſo that for the general part, require to be trained againſt walls.

The trees themſelves, though hardy enough in reſpect to cold, yet the bloſſom and young fruit are extremely impatient of froſt and cutting winds, which generally reign in this country at early ſpring, when the trees bloom and ſet their fruit: the trees, therefore, ſhould be indulged with the ſhelter of a warm wall, or other ſubſtantial cloſe fence, to which they ſhould be planted cloſe, and their branches regularly trained, which is neceſſary, not only to defend the bloſſom and young fruit the better from the inclemency of the weather, but alſo that they may have all the advantages of the ſun's influence, to accelerate its ripening, as well as to give it colour and flavour, which many ſorts, even with all the aid in our power to give, hardly effect in unfavourable ſeaſons in this country.

The proper aſpected walls or expoſure for the fine ſorts, is that of a due ſouth; ſome may alſo be planted upon an eaſt aſpected wall, and in favourable ſeaſons the trees will alſo ſometimes ſet and ripen fruit tolerably on a weſtern aſpect. However, where there is walling enough, let the capital ſorts be always planted againſt ſuch walls, &c. that enjoy the greateſt degree of the ſouth ſun, as even that aſpect, in ſome ſeaſons, is barely

ſufficient to ripen ſome of the late ſorts of theſe fruit, in any part of this iſland.

Such of the forward kinds that you deſire as early as poſſible, ſhould have the warmeſt ſituation on the beſt ſouth wall, which, though ſome are inferior in ſize and flavour, yet when obtained at the earlieſt ſeaſon, they are highly acceptable as a rarity in the deſert.

With reſpect to ſoil, the Peach-tree will proſper in any common ſoil of a garden, where it is not leſs than fifteen or eighteen inches depth of proper ſtaple, i. e. ſuch that is proper for the culture of common kitchen herbage, and where moiſture is not very copious; but if the depth of good ſoil in the fruit-tree borders is two or three feet, it will be the greater advantage.

The breadth of the borders againſt the walls, where it is intended to plant theſe trees, ſhould never be leſs than three, but thoſe of ſix or eight feet is the moſt proper width.

If the natural ſoil of the borders is of a moderately light, pliable nature, and of proper depth, it is a happy circumſtance; and if it is of a loamy temperature, it will alſo be a particular advantage, provided however there is ſuch depth of proper ſtaple as above noticed, before you come at gravel, clay, or any other bad ſoil at bottom, when nothing more than common digging is neceſſary; but where there is leſs than that depth, the borders muſt be raiſed with a due portion of good freſh earth and rotten dung, working the whole well together.

Where good rich or pliable loam could be eaſily obtained from the ſurface of ſome contiguous paſture, common, or other field, and with ſtore of rotten dung, working or blending the whole with the natural ſoil of the border to the proper depth, it would form a fine compoſt, and the trees will proſper, and be of long continuance.

But if the ſoil is naturally ſtiff and clayey, or of any other ſtubborn or very moiſt nature, it may be mellowed by adding dry ſubſtances, ſuch as coal aſhes, drift ſand, road ſoil, and other ſimilar materials, and plenty of rotten dung, working the whole with the natural ſoil to the above depth.

Where any one is ſo happy to poſſeſs a ſoil whoſe natural goodneſs renders all foreign aſſiſtance unneceſſary, no more need be done than digging the borders one or two ſpades deep, and it is fit for the reception of the trees. See KITCHEN-GARDEN, BORDERS, &c.

*Of Planting the Trees.*

The ſeaſon for planting is October and November, or even any time in open weather till March, in dry warm ſoils; but in moiſt or wet ſoils, we prefer the ſpring for that work.

Peach-trees, and, in ſhort, all others that are deſigned for walls, ſhould be planted in their places of final deſtination when they are one year old, i. e. when their heads are of one ſummer's growth from the bud, and with their ſaid heads entire for the preſent, (ſee *Heading them down)* that we may have the opportunity of training them from their origin, as it were, and in their proper poſition in the places where they are finally to remain; for the great art in forming a wall-tree depends entirely upon the due pruning and training the two firſt years, after making the firſt ſhoot or head from the budding.

But if any one is in haſte to have his walls covered at once, as it were, with bearing trees, he may be ſupplied with ſuch at moſt of the nurſeries, which are what the nurſerymen call trained trees, which they ſell from five to ten ſhillings per tree, according to the ſorts, ſize, and property of growth. Every one may do as they pleaſe, but for my own part I always preferred thoſe of one year from the bud; for theſe reaſons, firſt, that trees of that age ſooner and more firmly eſtabliſh their roots, which is an eſſential point to keep in view; and ſecondly, becauſe I would have the tree under my own management from the beginning, which I always found to be of importance.

The diſtance theſe trees ſhould be planted from one another is fifteen feet, and if the walls are high, half or full ſtandards may be planted between the dwarfs, to occupy the upper part while the dwarfs grow up to fill that ſpace, for no part of good walls ſhould be left unoccupied.

The rule is this, if the walls are not above ſix or eight feet high, plant none but dwarfs, and theſe at fifteen feet diſtance; if the walls are nine feet high, half ſtandards, of about three or four feet ſtem may be planted between the dwarfs; and if the walls are ten or twelve feet, or more in height, full ſtandards, of ſix feet ſtem, ſhould be planted to occupy the upper part; and as the dwarfs are to be the principal reſidents, way muſt be made, as their branches gradually advance, by cutting away the lowermoſt ones of the ſtandards by degrees annually, and at laſt, in ſeven, eight, ten, or more years, as you ſhall ſee neceſſary, the

the ſtandards may be entirely taken away, that the dwarfs may advance, and fill the whole ſpace of walling.

The mode of planting being fixed on, mark out on the walls the diſtances as above for the trees.

Then, having recourſe to the nurſery, let the trees be taken up with all their roots as entire as poſſible, for this is of much importance; the extreme ends of all of which ſhould be tipped, i. e. a little ſhortened, and thoſe of broken or bruiſed ones ſmoothed, ſee PLANTING, preſerving the heads entire for the preſent. Holes or pits are then to be opened, capacious enough to receive the roots freely every way. Place the tree therein, about three inches from the wall, with the bud outward, and then break and trim in the earth regularly between all the roots and ſmall fibres, and tread the whole gently, to fix the whole plant in its proper poſition; then directly tack the head to the wall, or tye it to a ſtake, to ſecure it from the power of boiſterous winds till March, when it is to be headed down. See *Heading Down.*

If the enſuing ſpring or beginning of ſummer ſhould prove very dry, indulge the trees with moderate waterings once or twice a week, according to the drought and heat of the ſeaſon, which will encourage them to puſh out more freely and ſtrong after heading down.

*Of Heading Down, and Manner of Pruning, to give the Trees their due Form.*

The trees being planted with their firſt heads from the bud entire, as we adviſed; the next neceſſary culture is to perform the operation of heading them down, which is to be done juſt as they begin to ſhoot, and the proper time is March.

This work conſiſts in ſhortening the head, or firſt main ſhoot down within five or ſix eyes of the bud, or place of its origin, ſloping it off on the ſide next the wall, juſt above an eye, which is a neceſſary operation, both to dwarfs, half, and full ſtandards, that are planted againſt walls; that by ſtopping its upright direction, it may throw out ſeveral lateral ſhoots from the remaining lower part to the right and left, and conſtitute the proper foundation for forming a wall-tree, whoſe firſt branches ſhould always proceed on both ſides, from within ſix inches of the place of inoculation, whether dwarfs for the lower part, or ſtandards for the middle and top of the wall; and that if the heading down was omitted, the conſequence would be, the tree would advance with a naked ſtem, and leave almoſt one half of the allotted ſpace of walling unoccupied.

Therefore, pay no regard to the firſt head from the bud, howſoever large and fine it may appear, but cut it down as above; for the general formation of the tree depends entirely upon the form acquired by this practice, and the two ſucceeding years pruning. See *Heading down Trees.*

*Firſt Pruning after Heading Down.*] The trees being thus headed down, they will ſoon after produce one ſtrong ſhoot from each remaining eye, obſerving that ſuch as proceed immediately from the front and back, are to be conſtantly rubbed off cloſe, but all thoſe that advance from the two ſides are to be preſerved entire, which, in June, when of due length to admit of laying in, ſhould be nailed cloſe to the wall, continuing them thereto at full length during the ſummer.

At the fall of the leaf following, proceed to give them their firſt winter pruning.

This may be done any time from November till March: you are now to examine the number of ſhoots each tree produced the preceding ſummer from the effect of heading down, and to prune them accordingly; for example, if there are two ſhoots, one on each ſide, they are both to be retained, and to encourage their furniſhing a farther ſupply of branches, ſhorten them to eight or ten, or if of very ſtrong growth, to twelve or fifteen inches, and nail them horizontally to the wall.

If there are three ſhoots, the middle one of which is to be cut out cloſe, and ſhorten the other two as above, and nail one to each ſide in a horizontal direction; but if the middle ſhoot of the three be conſiderably weaker than the other two, it may be retained, and nailed in at full length, which probably will furniſh a fruit or two, while the other two are providing a farther neceſſary ſupply of wood; but if it is a ſtrong ſhoot, cut it clean away.

If the tree is furniſhed with four ſhoots, two on each ſide, retain them all, and ſhorten them from ten to fifteen inches, according to their ſtrength, as above, and nail them equally to the right and left.

And if there are five ſhoots, and that thoſe on the ſides are ſtrong, and the middle one weak, ſhorten the former as above, and lay them horizontally, and nail in the middle one entire; but if the latter is nearly of equal ſtrength, or ſtronger than the others, cut it clean

clean out, which, if left, would draw the principal part of the nourishment, and impoverish those of the two sides, which should now be wholly attended to, for the middle will always furnish itself in due time.

One fundamental rule to be observed, is, that your tree, at this period of growth, should, if possible, proceed with shoots of an equal strength and number on each side, and depends principally upon two or four good branches, shortened and trained equally to the right and left, in a nearly horizontal direction, which will not fail in their turn to furnish you with more to occupy the wall upward. See WALL-TREES.

*Second Year's Pruning.*] The trees having had their first year's pruning, observe the following rules in their second year's culture.

During summer, all shoots that arise from the upper and under side of the former year's horizontals, are now to be retained and trained entire, and all buds or shoots that proceed immediately from the front and back part of the said horizontals, should be constantly rubbed off (see *Rubbing off the Buds*), because they cannot be trained consistent with the necessary form and regularity of the tree, having particular regard, however, to reserve all the regular shoots, and train them in at full length; for, except in some particular instances, the shoots must not be shortened in summer, therefore continue them to the wall entire till the winter pruning.

In November, when the leaves are fallen, or any time betwixt that and the beginning of March, you may proceed to the second winter pruning; in performing this, we, for example, will suppose the tree in the first pruning to have been trained with four horizontals, that is, two on each side, and that each of these produced two or three well-placed shoots the preceding summer, or as many as to make the tree now possessed of eight, ten, or twelve branches; now, if these stand four, five, or six on one side, and as many on the other, it is a happy uniformity, and all of which are to be retained, and that to procure still a farther supply of horizontals, each of the above are now to be shortened according to its strength; if they are weakly, cut them to six or eight inches, and if of middling growth to ten or twelve, and if very strong ones to about fifteen or eighteen inches, and train them to the wall horizontally, at six inches distance, observing that the opposite branches of each side range exactly in an equal position.

But where it happens that there are an unequal number of shoots, as for instance, four, five, or six on one side, and seven, eight, or more on the other, and that they are all of tolerable strength; then, to render both sides nearly equal, some of the weakest and worst placed on the fullest side should be cut out.

Observe to proceed as near as possible with an equal number and strength of horizontals in both sides, extending the lowest branches the longest, and if you have now five, six, or eight on a side, trained at five or six inches distance, your tree will begin to assume a handsome form, and next summer you may expect some fruit.

*Observations on the general Pruning of these Trees.*

Having in the preceding head exhibited the manner of pruning and training, to give the trees their necessary form, and the conducting them to a bearing state, we now come to illustrate the method of general pruning.

The general pruning is performed twice every year, i. e. summer and winter. See their *General Summer and Winter Pruning.*

Previous to the general pruning, observe, that Peaches and Nectarine-trees always produce their fruit upon the one year old shoots, that is, the shoots produced each summer bear the succeeding year, and the same individual shoots rarely bear but once, nor do they furnish good bearing wood after the first year, so that the grand article in pruning, is to procure an annual succession of these young shoots in every part, from the very bottom to the extremity every way of the tree, which are to be obtained principally by shortening, in winter pruning, those of every year, whereby they furnish, at the same time, both a proper crop of fruit, and supply of bearing wood.

The great art in pruning and training a Peach and Nectarine-tree against walls, is to preserve uniformity in every part from the beginning, having strict regard that both sides to the right and left advance with equal strength, and number of horizontals, whose numbers on each side should be equally encreased every year, and those trained constantly in a nearly horizontal position, see WALL-TREES, at five or six inches distance one above another, till by degrees they cover the whole space of walling allotted for them, both in breadth and height; for this is very essentially to be observed.

After the tree is thus formed and conducted

ducted to a bearing ſtate, its duration, beauty, and fruitfulneſs depends wholly upon proper pruning every ſummer and winter.

The general ſummer pruning conſiſts in reforming the irregularity of the numerous ſhoots then produced, and training to the wall at full length, in every part, all regularly placed ones, as ſucceſſion-wood for next year's bearing, for the great art is to procure a due ſupply of theſe every ſummer in all parts of the tree.

And the general winter pruning comprehends a general reform among all the branches and ſhoots of all ages, ſizes, and ſituation, ſuch as the retrenching all worn-out and naked branches, as they from time to time occur to make room for thoſe that furniſh the beſt bearing-wood, ſhoots of the preceding ſummer; at the ſame time ſelecting and retaining in every part the beſt of the ſaid ſhoots for next ſummer's bearing, cutting out unneceſſary and irregular ones, and all uſeleſs ſhoots in general, as well as part of the former year's horizontals, to make due room to train the proper uſeful ſhoots; all of which ſhould be ſhortened, to promote their emitting laterals in ſummer for bearing the year after, and the whole then nailed cloſe to the wall in regular order.

*Of the General Summer Pruning.*

The time to begin the ſummer pruning is in May or June. Every one knows that in ſpring a Peach-tree abounds with a great number of ſhoots, ariſing from every ſide of the laſt year's horizontals or preſent bearers, probably three times more than are uſeful, or than are wanted, or can poſſibly be trained in without confuſion; you muſt therefore thin them, and eaſe the tree of all that are irregular, and ſuch that are evidently uſeleſs and ſuperfluous, at the ſame time retaining a ſufficiency of the regular ſhoots, that is, two, three, or four of the ſide ones upon each horizontal, to be trained for next year's bearing.

The rule is this: each of the laſt year's horizontals will probably produce from three to ſix, or more ſhoots, and of theſe, ſome proceed from the upper and under ſides, and ſome from the back and fore parts; thoſe of the former ſituation, i. e. from the upper and under ſides, are to be regarded as the only proper regular ſhoots, and are to be principally attended to, retained, and trained in at full length, to prune upon in winter for bearing the ſucceeding year; but thoſe that proceed directly foreright from the front, and thoſe from the back of the horizontals, or from any of the other parts of the tree in that irregular direction, muſt be rubbed off cloſe, becauſe, by their ſituation on the branches, they cannot be trained with due regularity; therefore, that though good of themſelves, they are to be deemed irregular, or uſeleſs ſhoots, and ſhould be every where diſplaced, except in caſes where horizontals furniſh no other, when the beſt placed of them may be retained.

In reſpect to the regular ſhoots above deſcribed, examine, as you go on, their ſituation and number upon each horizontal; if two or more ſhoots riſe from the ſame eye, retain only one of them; and if the tree is but a moderate ſhooter, it is neceſſary to diſburthen it of all that are evidently ſuperfluous, which are ſuch ſhoots that, though good and well placed, yet if there are four, five, or more on a horizontal, where only one or two is apparently neceſſary for next year's bearing, ſome of the weakeſt and worſt placed, or any remarkably luxuriant ones ſhould be cleared away, retaining however, where practicable, always two of the beſt ſituated and faireſt ſhoots upon the weak, and three or four on each of the middling and ſtrong horizontals, which, though double, or even treble of what will be apparently wanted, it is eligible culture to reſerve enough to chuſe from in winter pruning, training the whole at full length during ſummer.

But where a tree ſhoots very vigorouſly in general, I would adviſe to reſerve as many of the ſide-ſhoots of each horizontal as there are tolerable room to train at full length, which, by dividing the ſap among many, checks luxuriance, which would probably take place in a ſmaller number, for the natural inclination of theſe ſort of trees ſhould, in ſome degree, be followed.

Another circumſtance to be attended to in thinning and regulating the ſhoots, is to leave one good ſhoot at, or as near the end of each bearing horizontal as poſſible, that it may draw the ſap through the whole branch to the nouriſhment of the fruit.

All weak ſhoots riſing from the old wood muſt be diſplaced, unleſs any regular placed ones appear uſeful to fill a vacancy.

If any remarkably vigorous or luxuriant ſhoot ariſe either from the bearing horizontals, or any of the older branches, examine its ſituation and ſtrength, and conſider whether it is wanted; if it is likely to impoveriſh the

the neighbouring ſhoots of moderate growth, or that it is not immediately wanted to fill a vacancy, cut it out; but if uſeful, either to fill a vacancy, or to prevent an apparent one, or to exhauſt too abundant ſap, retain it, and pinch it in May or early in June to four or five eyes, and you will procure one middling ſhoot from each eye the ſame year, to train in, to chuſe from in the winter pruning.

All thoſe very rank or luxuriant ſhoots, diſtinguiſhed ſingularly from the generality of the others of the ſame tree, by their extraordinary ſize, green colour, and often redneſs at the tips, ſhould be cut out from every part, unleſs you have no other reſource to fill a vacancy, when ſuch that are duly placed for that purpoſe may be reſerved and pinched as above obſerved.

Attention ſhould always be had to the bottom or lower part of the trees, eſpecially thoſe that are aged; if any ſtrong ſhoot ariſe in thoſe parts, you muſt preſerve it carefully to ſucceed worn-out or naked branches, which are cut away by degrees, and if there is a preſent vacancy, pinch it early in June to four or five eyes, to furniſh lateral ſhoots the ſame year, to be ready againſt the winter pruning.

Where a vacancy or want of wood is diſcovered, at this time, in any part, and that there is only one ſhoot where two, three, or more are neceſſary, ſhorten or pinch the ſaid ſhoot to three, four, or five eyes, in May or early in June, and it will afford as many laterals the ſame year to fill the vacant ſpace.

In the whole operation of ſummer pruning, obſerve, that all the regular ſhoots you judge neceſſary to retain to prune upon in winter, muſt be left entire, ſhortening none now, except in caſes of vacancy as above, and all irregular and other uſeleſs ſhoots that are now to be taken out, muſt be rubbed or cut off as cloſe as poſſible, leaving no ſtumps, which would ſhoot out from every eye, and fill the tree with innumerable uſeleſs ſhoots, and choak up and darken the fruit, and deprive it of the neceſſary benefit of ſun, air, ſhowers, &c. and which would require much time to cut out in the winter pruning.

It is neceſſary to obſerve, that if the above operations are begun early in ſummer, the ſhoots that are to be diſplaced, may readily be rubbed off with the thumb; but obſerve, if you delay the work till the wood begins to harden, they will not break off eaſily without damaging the mother-branch, therefore uſe the knife, and cut them as cloſe as poſſible.

After the above regulations, let all the remaining ſhoots, when of due length, be trained cloſe to the wall unſhortened, and as their ends advance, continue to train them ſtill along at full length, and which are to remain entire until the winter pruning; for in the common courſe the ſhoots muſt never be ſhortened in ſummer.

Theſe are nearly all the directions we have to advance relative to the ſummer pruning, the utility of which, if the operation is performed in due time, is very great both to the tree and fruit.

Therefore, if the operations are began in May, only juſt rub off all the ill-placed buds, that is, foreright ones, and thoſe behind the bearing horizontals, and ſuch others that are evidently uſeleſs, as formerly obſerved; and in June, when the uſeful or regular ſhoots are of proper length, they are eaſily and expeditiouſly trained in, for every one points to its proper place; beſides, when the work is begun early, it can be performed with conſiderably more expedition and truth, as the uſeleſs buds or ſhoots may then, with the utmoſt facility, be rubbed off cloſe with the thumb, without the uſe of any inſtrument, and the early operation will contribute very conſiderably to the ſize and goodneſs of the fruit, as well as beauty and duration of the trees.

The work however ſhould never be delayed longer than the beginning of June, or till the ſhoots have attained due length for training in, and not, as is often the caſe, wait till they are two or three feet in length, and form ſuch a thicket and confuſion, that the moſt expert pruner would be at a loſs to know where to begin to break through ſuch obſcurity, to determine what is neceſſary to be done, which, beſides, is highly prejudicial to the proſperity of the fruit, the main object, as well as to the beauty and duration of the tree; and the confuſion occaſioned by ſuch a thicket of wood and leaves prevents you from cutting cloſe, and the tree becomes full of diſagreeable ſtumps, producing uſeleſs ſhoots from every eye, which take up much time to remove in the winter pruning, and upon the whole the fruit being hidden, choaked up, and as it were buried behind ſuch a thicket, becomes tender, as is evident from the colour, which

ſcorch-

is rather white than green, and when thus ſuddenly laid open to the air, joined to a ſcorching ſun, great part of it withers and drops off, which never happens when the fruit has from the beginning been inured to the weather, by early rubbing off the uſeleſs, and training cloſe the uſeful ſhoots, ſo as to give the ſun and air free admiſſion; but on the contrary the fruit always excels in ſize, colour, and flavour.

At this time of laying in, or dreſſing, i. e. June, we recommend the following obſervation, which could not be ſo diſcoverable at the earlier dreſſing, viz.

Where ſhort ſhoots, of an inch or two in length, appear upon this or the former year's horizontals, or ſides of the old wood, and that they apparently will not exceed that length, it is of utility to reſerve them, at leaſt till the winter pruning, becauſe they may prove natural fruit-ſpurs, which, at that ſeaſon, is diſtinguiſhable by having a cluſter of bloſſom buds. See the *Winter Pruning*.

If a vacancy is any where diſcovered early in ſummer, you may pinch ſome of the ſtrongeſt neighbouring ſhoots to three or four eyes, and they will furniſh you ſhoots the ſame year, to chuſe from in the winter pruning. See *Pinching the Shoots*.

Do not pull off any of the leaves at this time, as often practiſed, with a view to admit the ſun, for theſe are neceſſary to the growth, both of the young ſhoots and fruit, ſo ſhould never be taken away, unleſs there is indeed in any part ſo great a thicket as to darken the fruit conſiderably, when a little thinning may be neceſſary; in other caſes that work muſt be diſpenſed with till the fruit are full grown.

After the trees have been ſummer-dreſſed, according to the preceding directions, you muſt not forget to review them once a fortnight, to rub off any unneceſſary or ſtraggling ſhoots that may ariſe, which is ſoon done, and to faſten up any ſhoot that may ſtart from its place, or project from the wall, as well as to continue the trained ſhoots in general thereto, as they advance in length.

One thing more, which is neceſſary to obſerve in the ſummer dreſſing, is the blight which attacks theſe trees: this diſorder is the effect of noxious winds, that occaſion the curling up of the leaves, which become thick, clammy, yellowiſh, red, and ſcabby; and attacks the ends of the ſhoots, and proves very injurious both to the young ſhoots and fruit, and often their deſtruction; for the blighted leaves exhauſt the ſap, at the expence of all the other parts of the tree. When your trees are firſt attacked, there is no other remedy for this accident than to pick off all the curled leaves as ſoon as diſcoverable, and alſo cut off, below the diſorder, all the infected part of the ſhoots, which generally form a rough diſagreeable buſh or thicket; this enables the ſap to puſh out new ſhoots lower down, for next year's bearing. So deſtructive is this infection, that it frequently deſtroys in a ſhort time the whole leaves of a wall of trees; and when theſe are gone, the principal part of the fruit ſoon after follow, which generally withers and drops, as likewiſe the young wood, for next year's bearing, either dies or becomes ſtunted. Various other methods have been tried to prevent the ſpreading of this peſtilence, but nothing effectual.

Inſects alſo often prove very injurious to theſe trees; a fumigating engine lately invented is recommended, in which is burned tobacco, the ſmoak of which iſſuing with a perpetual ſtream, is applied to the trees attacked by the vermin, which infallibly deſtroys them, without injury to the trees or fruit. See FUMIGATION, INSECTS, &c.

*Of the General Winter Pruning, &c.*

The winter pruning may be executed any time from the fall of the leaf in November, until the beginning of March; for no weather has any particular effect with regard to proving injurious to the new-cut ſhoots, as ſometimes imagined.

This work however ſhould never be delayed till late in ſpring, becauſe the bloſſom buds will be ſo very turgid or ſwelled, that numbers of them will be unavoidably rubbed off in performing the operation of pruning and nailing; though ſome wait till this period, that they may better judge of the good or bad buds, and of the wood-buds from thoſe that produce bloſſom and fruit. This is of ſome importance, but the ſap is generally riſen ſufficiently in January, or ſooner, to ſwell the buds, to enable you to diſtinguiſh them.

As theſe trees always bear their fruit upon the one year old wood; that is, the ſhoots produced each ſummer bear the fruit the ſummer following, ſo that the fruit-buds are principally to be looked for upon theſe ſhoots.

Wood-buds are diſtinguiſhable by their being long and firm; bloſſom or fruit-buds are round, ſwelling, thick, and ſoft.

It muſt be obſerved that good bloſſom buds are always double, two at an eye, having a

leaf-bud or ſhoot between them; thoſe that are ſingle, though they ſometimes have a leaf-bud, and blow pretty well, never ſet fruit ſo freely as the twin bloſſoms.

Great attention muſt always be had to keep every part of the tree well furniſhed with an annual ſupply of young wood, of the former ſummer, for bearing next year, advancing, as it were, gradually one behind another, from the bottom to the extremity every way; which is eaſily acquired by properly ſelecting, thinning, and ſhortening thoſe of every year, and by cutting out annually ſome of the old horizontals to make room for them. Likewiſe obſerve, that as the bottom of the trees are apt to become naked, be alſo watchful of that part, to retain in proper places an annual ſupply of ſtrong young wood, either to fill an immediate vacancy, or to be trained up gradually to ſupply the place of any naked or worn-out branch, that may happen either there, in the middle, or upper part; which are ſuch that ſupport little or no young wood, or produce weak and a ſcanty portion of ſhoots, and ſhould, wherever they appear, be cut down to the great branch from which they proceed, or to any lower ſtrong young ſhoot they ſupport, or to any convenient branch ſupporting ſuch ſhoots: and part of the old horizontals muſt always be cut out annually, to make room to train in the bearing wood.

Previous to the performing the operation of winter pruning, it is eligible to unnail the greater part of the branches, and all the young ſhoots in general; you then have full liberty to examine the ſtate and ſituation of the whole, as well as to have due command in uſing your knife, and nailing the tree again in regular order, according to the ſituation and ſtrength of the general ſupply of young ſhoots neceſſary to be retained for next ſummer's bearing, &c.

The trees being unnailed as above, you ſhould firſt proceed to examine all the principal branches, and ſee if any are become naked, or worn out. Naked branches are ſuch that, as formerly hinted, have advanced a conſiderable length, and ſupport very little or no good bearing ſhoots, or lateral branches furniſhed with ſuch wood, and ſhould be cut out to their origin, provided there are proper young wood, or horizontals, well furniſhed with ſuch ſhoots, properly ſituated to be trained up to ſupply their places; for way muſt always be made for thoſe branches that furniſh the beſt young wood, both for bearing the following ſummer, and providing a further ſupply of ſhoots for future ſervice. And the worn-out branches are eaſily diſtinguiſhed by their uncommonly weak ſhooting, ſo ſhould be cut out as above, to make room to extend thoſe of better growth, as juſt obſerved.

From theſe you paſs to regulate the ſhoots of the year; of which you will find often, on the ſame tree, weak ones, middle-ſized ones, and ſome of very luxuriant growth; thoſe of the middle ſize are to be principally attended to; obſerving, as noticed in the ſummer pruning, that the proper ſhoots for our preſent purpoſe to train for next ſummer's bearing, are principally thoſe that grow upon the one year old horizontals, and of which we are now to ſelect and retain the moſt regular placed ones, i. e. ſuch that are the moſt properly ſituated for training cloſe and neatly to the wall, which are chiefly thoſe that proceed from the two ſides of the ſaid horizontals, ſo that keeping thoſe in view for training, clear away all the irregular and other uſeleſs ſhoots, as hereunder mentioned.

Suppoſe your tree to be chiefly of moderate growth, and here and there in it ſhoots of ſuperior luxuriance and rankneſs; theſe, whereever ſituated, muſt be cut out cloſe: but if the tree is in general vigorous or luxuriant, the ſhoots muſt only be thinned in a moderate way, as hereafter directed.

All ſhoots of extreme weakneſs ſhould be cut away, unleſs you ſhall ſee it neceſſary to keep one here and there to fill a vacancy, or as a reſerve in caſe of one the future year, in which latter caſe I would cut them down to an eye or two.

I do not comprehend by weak ſhoots thoſe ſhort ones an inch or two long, which I call natural fruit-ſpurs, and often furniſh excellent fruit, and muſt be retained.

All foreright ſhoots, and ſuch that proceed directly from the back of the branches, and in other irregular directions, that cannot be trained conſiſtent with the uniformity of the tree, and thoſe ariſing from the old wood, are alſo to be cut off cloſe, except in caſes of vacancy, and that there is no other reſource.

Cut away all ſtumps of laſt ſummer, and leave none now, cutting every thing cloſe.

During the whole operation of the above reforms, great attention muſt be obſerved in ſelecting and retaining all the well-placed regular ſide-ſhoots above deſcribed, which muſt next be regulated according to the following rules.

Having in this manner cleared your tree from worn-out branches, and from luxuriant, irregular,

irregular, and other bad ſhoots, there is nothing left but uſeful branches ſupporting horizontals, furniſhed with proper young wood, nearly of equal ſtrength, and you ſee your work clear; you have nothing now to do but ſelect and retain upon each horizontal a due portion of the beſt placed of theſe proper ſhoots, and retrench the ſuperfluous ones.

Examine therefore the number of proper ſhoots upon each horizontal, and their ſtrength, keeping in mind, that the middling ſtrong ones are to be principally attended to. We adviſed in the ſummer pruning to leave upon each horizontal two, three, or four ſhoots, according to the ſtrength of the tree in general: now, if your tree is fully trained, no more than one or two, as you ſhall ſee neceſſary, need be left upon each horizontal, except in caſes where a tree is very luxuriant, or where there is a very wide ſpace to fill, or a vacancy in its neighbourhood; but if the tree is ſtill in training, you may retain two or more ſhoots upon each bearer, as you ſhall judge expedient, to forward the tree to its intended form. But ſuppoſe you are upon a full trained tree, or ſuch that are nearly ſo, and that you judge one of the young ſhoots on each horizontal is ſufficient, keeping in view they ſhould be trained about five, ſix, or ſeven inches diſtance; on this conſideration you are to ſelect the beſt of the lowermoſt of theſe ſhoots, unleſs you ſhall judge neceſſary to advance the length of the branch; then chuſe the beſt of the uppermoſt, obſerving that whatſoever ſhoot you fix upon, to cut off the upper part of the horizontal on which it ſtands, cloſe to the ſaid ſhoot, or if you leave two or more ſhoots upon each horizontal, let one be near the upper, and the other near the lower part thereof, on the oppoſite ſides, and cut down the horizontal to the uppermoſt of the two ſhoots, ſo that by cutting away part of each of the former year's horizontal, the remaining part is terminated by a young ſhoot, which now commences the bearer or horizontal of the enſuing year.

Obſerve, where two or more ſhoots ariſe from the ſame eye, never leave but one.

Where any ſhoots riſe from the ſides of the old wood or main branches, and which you ſhall judge neceſſary to retain, either to fill a preſent vacancy, or to be ready for an apparent one, it may be reſerved without ſhortening down the ſaid branch to it, as is neceſſary in the one year's horizontals, unleſs that part of the ſaid branch immediately from the ſhoot upward is naked, or unfurniſhed with young wood, in which caſe take it down to the ſhoot in queſtion.

Thoſe ſhort ſhoots or natural ſpurs, an inch or two long, above obſerved, may be retained wherever they appear, for they are generally well furniſhed with bloſſom buds.

Obſerve, that many of the principal bearing ſhoots which you now retain, will have probably put out ſeveral ſmall twigs or ſide ſhoots; theſe, being produced late, are generally ſpongy, beſides being ſuperfluous or unneceſſary, muſt be cut cloſe, leaving only the main ſhoot.

In cutting out the irregular and ſuperfluous wood in general, cut all cloſe, leaving no ſtump, which would ſend out ſhoots from every eye the enſuing ſummer, and crowd your tree with uſeleſs wood; and any of thoſe ſhort natural ſpurs of the former year, now devoid of bloſſom buds, or that exceed two or three inches in length, ſhould now alſo be cut away cloſe, but eſpecially ſuch that advance directly foreright.

After making theſe reforms of regulating and thinning, we proceed to conſider of ſhortening the remaining ſelect ſhoots, the utility of which is obvious; for as theſe trees always produce their fruit upon the one year old ſhoots, the ſame wood, by proper ſhortening in winter pruning, furniſhes, as well as fruit, lateral ſhoots the following ſummer, to bear the fruit the year after that; therefore, to procure an annual ſupply of young wood in the proper parts, we muſt not omit ſtopping or ſhortening that of each year in the winter pruning, by which each ſhoot will emit two, three, or more lateral ones the ſucceeding ſummer; whereas, if they were left at full length, the ſap which would have thrown out ſhoots below, would mount to the extremities, and leave the bottom bare, and in a ſhort time all the lower part of the tree would become naked, and furniſhed with bearing wood only towards the extreme parts. The rule of ſhortening is this; if the tree is in health, and of a middling free growth, ſhorten or cut off about one third of the length of each ſhoot; for inſtance, ſhoots of ten or twelve inches ſhould be ſhortened to ſix or eight; thoſe of about fifteen or eighteen inches ſhorten to eight, ten, or twelve; and ſo in proportion to the length and ſubſtance of the reſpective ſhoots; obſerving, where a tree is weak, or on the decline, and makes weakly ſhoots, to leave the ſhoots thin, and cut them ſhorter in proportion: on the contrary, where a tree is in general a vigorous ſhooter, leave the ſhoots

cloſe, and ſhorten them moderately, that by retaining a good deal of wood to divide and exhauſt the great redundancy of ſap, is the only means to reduce a luxuriant tree to a ſtate of moderate growth, and to bear plentifully.

In ſhortening theſe ſhoots, it is of importance to cut them juſt above a wood, or branch-bud, that it may produce a ſhoot for a leader, to draw the ſap through the whole horizontal, the more effectually to nouriſh its reſpective fruit. A wood-bud is with facility diſtinguiſhed from a bloſſom-bud, the former is long, narrow, and firm, the bloſſom-buds are roundiſh, thick, ſwelling, and ſoft; ſo that by cutting to a wood-bud you are ſure of a leading ſhoot, and the fruit will be well-nouriſhed; but where two bloſſom-buds appear on the ſame eye, a wood-bud alſo generally iſſues from between, ſo that if you cannot conveniently cut to a wood-bud, make the cut to a twin bloſſom-bud as above.

Thus much for the general directions to be obſerved in the principal winter pruning, although there are other circumſtances that cannot be conveyed by words, nor judged of but upon the ſpot, and depends chiefly upon practice.

We will however ſubjoin a few other particulars very neceſſary to be obſerved.

In the courſe of practice, you will meet with trees of very different habits of growth; ſome, for inſtance, are weakly, and produce ſmall or weak ſhoots; others are of a middling ſtate, ſhoot freely in every part, but not too vigorous, which is the moſt deſireable ſtate of growth of any; and ſome ſhoot very vigorous in almoſt every part. With reſpect to the former, if the tree makes very weak ſhoots, examine whether the diſeaſe is at the root, if it is, pull it up; if not, preſerve it, and dig in rotten dung, which often recovers theſe ſort of trees, obſerving to keep it thin of wood, and prune the ſhoots ſhort, even the beſt to five or ſix inches, till it recovers. In the ſecond caſe, the middling ſhooting tree is to be managed as in the general directions. And in the third inſtance, if the tree is remarkably vigorous, and bear little, it ſhould in ſome degree be humoured in its own way; for if you cut out many, and ſhorten conſiderably the remainder of theſe very vigorous ſhoots, where they are general, as is frequently done without mercy, ſuppoſing by that practice to check luxuriance, and ſo continue to prune, and depend entirely upon the ſmalleſt ones, the conſequence is, that by much thinning, and cloſe cutting vigorous trees, they continue to ſhoot ſtill with greater vigour and irregularity for ſeveral years, without being able to gain either form or fruit, till at laſt, by ſevere pruning, they paſs into the oppoſite extreme, become, as it were, tired with acting ineffectually, grow very weak and ſickly, and ſhoot no more. On the contrary, by following, in ſome degree, the inclination of the tree, and leave the ſhoots as cloſe as there are any tolerable room to lay them in, and ſhorten them very little, ſome of the ſtrongeſt not at all; and by thus leaving a good deal of wood, and that at a conſiderable length, the ſap is divided, and the luxuriance is checked; and in a year or two your tree will become a moderate ſhooter, and furniſh fine young wood, and bear plentifully.

*The Method of Nailing them.*

The trees being pruned, they ſhould be directly nailed to the wall; this however ſhould always be done as you go on, that is, as ſoon as one tree is pruned let that be nailed before you prune another.

This operation is ſufficiently explained under the article WALL-TREES and NAILING: we ſhall juſt obſerve, that as your trees having, previous to the pruning, been entirely unnailed, you have the opportunity of nailing the whole with the greateſt regularity, obſerving to bring the lowermoſt branches on each ſide down horizontally, and train them along perfectly ſtrait, and ſo much horizontal, that the extremities be but a few inches higher than the bottom: nail them cloſe, proceeding in the ſame manner with the next immediately above them; and ſo of all the reſt, making the oppoſite principal or mother-branches on each ſide, range nearly in the ſame poſition, preſerving on each ſide an equilibrium of number and ſtrength, obſerving nearly the ſame of their reſpective horizontals or bearers, training them ſtrait and regular, at five or ſix inches diſtance from one another, obſerving if the pruner has left in any place more wood than can conſiſtently be new laid in; the nailer muſt regulate that according to his diſcretion, by either cutting out entirely ſuch ſuperfluous or unneceſſary ſhoots, or take it down to one eye to furniſh a ſhoot for another year, if he ſhall judge it of utility.

*Of defending the Bloſſoms.*

Peach-trees come into bloſſom early in ſpring, when cutting froſts prevail, which, in

in ſome ſeaſons, is ſo ſevere as to cut off the whole. Not only the bloſſom is liable to this diſaſter, but alſo the young fruit, till they are as large as ordinary cherries, which oblige us to have recourſe to all poſſible means to defend them.

The dangerous time laſts a month or ſix weeks; various ways have been tried to ſhield the trees during that period; ſome cover with large garden mats, which I have often found of great uſe; but where there are much walling, it takes up much time to cover and uncover, as the danger threatens, for they muſt only be uſed when there is apparent danger: free air and light muſt be admitted, ſo that if the mats are nailed up in an evening when there is an appearance of a cutting froſt, they ſhould be removed again in the morning, if the weather is quite mild; but if not, they may be permitted to remain till it is: do not omit however to take them down when the weather changes; and ſo continue their uſe only occaſionally, till your fruit are as big as large peas at leaſt.

This is the principal expedient in practice to defend theſe trees, which, after all, it ſometimes does not ſecure us a quarter of a crop; it however ſhould not be omitted in hazardous times, eſpecially to ſome of the early and choice ſorts. See COVERING TREES.

There is another method which I have ſometimes experienced to ſave a few fruit, when all that have been fully expoſed was cut off; this is to procure a quantity of cuttings from the branches of evergreen trees, ſuch as thoſe of laurel, yew, ſpruce-fir, &c. and ſtick them moderately thick between the branches of the Peach-tree, ſo as the leaves of the cuttings cover the bloſſom; theſe ſhould be placed when the bloſſoms begin to open, not too thick to darken it, and may be permitted to remain until the beginning of May, when the fruit will be ſet, and paſt danger. In default of the above cuttings, I have uſed branches of dried fern.

Neither of theſe methods of covering, nor indeed any other can we recommend as generally effectual; but a poor expedient is better than none; they often inſure a few fruit, when thoſe that are fully expoſed are all deſtroyed by the froſt.

*Thinning the Fruit.*

In favourable ſeaſons Peach and Nectarine-trees ſometimes ſet their fruit very thick in every part, often double or treble the quantity that have room to grow, or the trees capable of nouriſhing, and frequently the fruit are ſet only here and there in cluſters; in either caſe they muſt be thinned, otherwiſe the fruit will not attain half its common ſize, and during their growth would thruſt one another off; beſides, if the trees are overloaded, they would produce but very weakly ſhoots for next year's bearing, and would be two years before they recovered themſelves.

This work ſhould be performed when the fruit have attained nearly the ſize of ſmall cherries, which will be about the beginning or middle of May, for if you thin them ſooner, froſts may deſtroy the remainder, and you have no reſource left.

The rule of thinning is, if the tree is weak the fruit muſt be left thin, not more than one or two on the larger ſhoots, and none upon the ſmall ones, which is the only way to inſure wood for another year: upon trees of a middling ſtrong growth you ſhould retain but one fruit upon the ſmaller ſhoots, and two upon the middling ſized ones, and three upon the ſtrong ſhoots: but the ſmalleſt kinds of fruit may be left a little thicker in proportion, and the large ſorts ſhould be thinner, i. e. about ſix inches diſtance upon each ſhoot, and the largeſt of all eight or ten. In performing this work, obſerve to ſelect and retain the beſt placed, largeſt, and faireſt fruit, in every part, according to the above rule; and in removing the ſuperabundant ones, be careful not to diſturb theſe. Leave no where two or more upon the ſame eye, eſpecially if one exceeds the other in ſize, taking off the ſmalleſt, which the other would ſtarve; but if they are of equal ſize, you may, if it ſhall ſeem neceſſary, leave both of them.

We formerly obſerved, that it was of utility to preſerve a ſlight coverture of the leaves of the tree, by way of ſhade to the fruit during their growth, and until they begin to change colour: when they have attained that ſtate of perfection, it is neceſſary to pinch off a few of the leaves that immediately cover the fruit, to admit the ſun to give it colour and flavour.

Do this however regularly, and thin the leaves by degrees, which ſhould be pinched, and not torn off, which would mangle the eyes, and prevent the fruit buds from forming themſelves for next year.

*General Obſervations.*

Peach-trees, from the time of heading down to the ſixth or ſeventh year, may be ſaid

ſaid to be in a ſtate of training, though they frequently begin to bear the ſecond or third year after the operation of heading down; and in five, ſix, or ſeven years will bear pretty plentifully, according to their ſize, for they will not have attained their full growth till they are ten, twelve, or fifteen years old, according to the extent of walling they have to cover, at which age they will be arrived at the beginning of their ultimate ſtate of vigour and perfection of bearing, which they generally acquire between the ſeventh and fifteenth year, and in which they will continue for twenty or thirty years to come; for theſe trees, with due management, will endure fifty or ſixty years, provided no accidents happen, ſuch as violent blights, or tainted with gum, or attacked by vermin; ſo that the opinion of ſome, that Peach-trees are ſeldom of more than twelve or fifteen years duration, is erroneous, and muſt be given up, for it is owing only to bad management that they do not laſt as long as other fruit-trees.

The trees may be ſaid to be in their third ſtate when they begin to decline through age; but if our general directions in pruning are obſerved, this ſeldom happens until they are upwards of thirty or forty years old, when they ſhould be cheriſhed by leaving only the beſt young ſhoots, and that moderately thin, and which ſhould be pruned ſhorter than the general rules, and make the moſt of ſtrong young wood that riſe from or near the bottom, to ſupply the place of worn-out branches.

When it is obſerved any trees approach near their end, and the bottom of the walls become naked, young trees ſhould be planted in due time in the ſpaces between the old ones to ſucceed them, and as they ſhoot up lop off the lower branches of the old trees, which in four or five years may be taken entirely away; thus you may keep your walls always occupied, without intermiſſion.

It ſometimes happens that the trees do not bear fruit of the approved or deſired ſort, which is often the mortifying circumſtance when purchaſed in ſome nurſeries, and a very cruel one, after all the trouble of training, &c. To remedy this, you, in Auguſt, may bud ſome of the young ſhoots of the ſame year, in different parts of the tree, and as theſe advance cut the other parts away, and in two or three years they will ſpread conſiderably, and bear fruit.

If the gum has attacked any ſhoot of a tree, young or old, cut it off an inch below, to ſtop the communication, and prevent killing the whole ſhoot.

The utility of tillage to theſe trees is very obvious, and ſhould be performed every autumn and ſpring.

Dung, in moderation, is alſo of utmoſt utility in preſerving due vigour and health in theſe trees, and to promote the ſize of the fruit; let it be perfectly rotten, and added every two or three years, ſpreading it all over the border, and dig it in in the uſual way.

As to cultivating kitchen herbage on the borders, the moderate growing ſorts, ſuch as radiſhes, lettuce, ſmall ſallad herbs, kidney-beans, a few ſmall early mazagan beans, peas, &c. do very little or no injury to the trees.

Peach and Nectarine-trees are often planted in forcing-frames and hot-walls, to produce early fruit; the ſorts proper for this are the earlieſt kinds: for the method of performing it, ſee FORCING-FRAMES and HOT-WALLS.

*Of planting theſe Trees for Ornament.*

There are two varieties of Peach-trees that are eſteemed chiefly by way of curioſity and ornament, which we judge it moſt proper to ſpeak of under a ſeparate head. Theſe are, the

Double bloſſomed Peach-tree.——Dwarf Peach-tree.

The former of theſe has great beauty in its double flowers; it attains the height of common Peach-trees, and differs in nothing from them but in the doubleneſs of its flowers, which, like thoſe of the others, are ſucceeded by fruit: the tree makes a fine appearance in ornamental plantations.

The Dwarf Peach riſes but two or three feet high; the ſtem is ſmall, and hath very ſlender branches, which produce ſmall inſipid fruit, the ſize of a nutmeg. It is ſometimes planted in pots, and brought to table with the fruit upon for curioſity, and makes a ſingular appearance.

For purpoſes of ornament, any of the ſorts of Peach-trees may, with propriety, be admitted as ſtandards in the ſhrubbery, and will make a fine appearance when in bloom, and if they ſtand in a ſheltered ſituation, there will be a chance of having now and then ſome fruit from them: they may either be planted as ſtandard-dwarfs, or as half or common ſtandards.

The propagation of the Double Bloſſomed and Dwarf kind is effected by budding the ſame as common Peach trees.

*Third*

*Third Diviſion of Amygdalus.*

AMYGDALUS-NUCIPERSICA, the Nectarine-Tree.

Claſs, order, and characters the ſame as the Amygdalus.

The Nectarine and Peach-trees have been generally conſidered as diſtinct ſpecies, principally by the difference of their fruit; but late diſcoveries has determined otherwiſe, and that they are found to be varieties of one another, but which is the original is not yet agreed on; but certain it is, that there have been inſtances of Nectarines growing naturally on Peach-trees, accompanied by Peaches on the ſame branch; which very ſingular phœnomenon determines them to be varieties of one ſpecies.

Neither the trees, by their manner of growth, the wood, leaves, nor flowers of Nectarines and Peaches, can with any preciſion be diſtinguiſhed from one another; but the fruit is diſtinguiſhable at ſight in all its ſtages of growth: that of the Nectarine hath a ſmooth firm ſkin or rind, and the Peach is covered with a ſoft downy matter; the fleſh too or pulp of the Nectarine is conſiderably firmer than that of Peaches.

Their temperature and general culture is the ſame in every reſpect.

However, as they are generally conſidered as different fruit; we, for diſtinction ſake, range them in ſeparate diviſions, though all under the principal genus Amygdalus.

The varieties of Nectarines that merit eſteem are,

[1]*Fairchild's early Nectarine.*] A ſmall round Nectarine, of a bright red on one ſide, the other yellow; ripe beginning or middle of Auguſt.

[2]*Violet Nectarine.*] A middle-ſized fruit, purple on one ſide, the other of a yellowiſh green, tinged with red; ripe latter end of Auguſt.

[3]*Elrouge Nectarine.*] A middle-ſized long-iſh Nectarine, purple or dark red on one ſide, the other yellow, and the rind becomes ſhrivelled, and the pulp ſeparates from the ſtone; ripe end of Auguſt.

[4]*Newington Nectarine.*] A large beautiful Nectarine, being of a fine ſcarlet or bright red on one ſide, the other changing gradually to a bright yellow, and adheres to the ſtone; ripe beginning or middle of September.

[5]*Red Roman Nectarine.*] A fine large, round, dark red Nectarine, aſſuming a yellowiſh hue on one ſide, the whole becomes ſomewhat ſhrivelled, and adheres to the ſtone; ripe middle of September.

[6]*Temple's Nectarine.*] A middle-ſized long-iſh Nectarine, pale red on the ſunny ſide, the other a yellowiſh green, and ſeparates from the ſtone; ripe middle of September.

[7]*Tawney Nectarine.*] A middle-ſized round-iſh fruit, of tawney red on one ſide, the other a duſky yellow, and adheres to the ſtone; ripe in September.

[8]*Scarlet Nectarine.*] A middle-ſized, wholly red, beautiful Nectarine, the ſunny ſide being ſcarlet, the other a pale red colour, and adheres to the ſtone; ripe beginning and middle of September.

[9]*Brugnon or Italian Nectarine.*] A large fruit, deeply reddened next the ſun, and yellowiſh on the other ſide, and adheres to the ſtone; ripe in September.

[10]*Golden Nectarine.*] A middle-ſized round Nectarine, faintly reddened on the ſunny ſide, the other parts are of a golden yellow, and adheres to the ſtone; ripe late in September.

[11]*Murry Nectarine.*] A middle-ſized fruit, of a duſky purpliſh red on one ſide, the other a yellowiſh green, and adheres to the ſtone; ripe beginning or middle of September.

[12]*Virmaſh, or Peterborough Nectarine.*] A middle-ſized, round, greeniſh Nectarine; ripe middle or end of October.

Of the above twelve varieties of Nectarines, if you would cultivate only the beſt, I ſhould adviſe to plant the following. Fairchild's Nectarine claims a place for its early perfection. The Violet and Elrouge Nectarines are pretty fruit, ripen freely, and their flavour is rich and vinous. The Newington and Roman are the largeſt, moſt beautiful, and beſt flavoured Nectarines in the world. Temple's Nectarine is alſo a very good fruit, and is well eſteemed; and the Virmaſh or Peterborough Nectarine merits a place in the collection, becauſe it ripens late, and furniſhes a variety for the deſert after all the others are gone.

The Nectarine-tree is in temperature and manner of growth, in every reſpect, like the Peach, and like that tree requires to be trained againſt the walls, and in the ſame aſpect and ſoil.

Its propagation alſo, and whole management in all its ſtages of growth, is the very ſame as the Peach-tree.

Therefore, to avoid unneceſſary repetition, the reader is requeſted to turn to the *Amygdalus-Perſica*, or Peach-tree, for the method

of

of propagation, planting, pruning, and every other article of culture, where an ample direction, equally applicable to the peach and Nectarine, is given.

ANACARDIUM, Acajou, or Caſhew-Nut.

There is but one ſpecies; it is of the tree kind, a native of both Indies, and retained here in ſtoves for curioſity.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, five ſharp-pointed deciduous leaves. COROLLA, five long, narrow, reflexed petals. STAMINA, ten ſhort filaments, and roundiſh antheræ. PISTILLUM, a roundiſh germen, inflexed ſtyle, and oblique ſtigma. PERICARPIUM none, the receptacle becomes a large round pulpy ſubſtance, crowned by a kidney-ſhaped nut.

There being but one ſpecies, it is named ſimply *Anacardium.*

This tree appears as a ſmall ſhrub here in our ſtoves; but in the Indies it riſes twenty feet in height, dividing into ſpreading irregular branches, decorated with large oval leaves, and ſmall white flowers in umbels at the ends of the ſhoots, ſucceeded by a large yellow pulpy receptacle, crowned by the fruit, which is a kidney-ſhaped nut, an inch long, containing an eatable ſweet kernel, very palatable when roaſted.

The propagation of this plant is by planting the nuts, which are brought hither annually by the Weſt India ſhips.

They are to be planted ſingly in ſmall pots, and plunged in the bark-bed, and the plants will appear in a month; continue them always in the ſtove.

ANAGALLIS, Pimpernel.

The plants are herbaceous, one of which is the common trailing annual Pimpernel, a weed of the garden and fields; and one is an erect, ſmall, ornamental perennial of the green-houſe.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, five-parted, and permanent. COROLLA is monopetalous, wheel-ſhaped, and five-parted. STAMINA, five erect ſhort filaments. PISTILLUM, a globular germen, ſimple ſtyle, and headed ſtigma. PERICARPIUM, a globular capſule, and many angular ſeeds.

The ſpecies that merit culture is,

ANAGALLIS *Monelli.*

*Monelli, or Perennial Anagallis.*] Anagallis with erect ſtalks, and ſpear-ſhaped leaves.

This is a low erect perennial, a foot high, ſomewhat buſhy, and cloſely adorned with leaves, by pairs, or by threes, and numerous wheel-ſhaped blue flowers on long foot-ſtalks, which make a pretty appearance.

The propagation of this plant is either by ſeed on a warm border in April, or by cuttings in the ſhade in ſummer, and muſt be potted and houſed in winter; ſhift them occaſionally into larger pots, removing them each ſhifting with the ball of earth entire about their roots, and give moderate waterings in common with other woody exotics of that department.

ANAGYRIS, Stinking Bean Trefoil.

This genus furniſhes two hardy deciduous flowering ſhrubs, adorned with oval leaves and long ſpikes of papilionaceous yellow flowers.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, a monophyllous, bell-ſhaped, five-parted cup. COROLLA is papilionaceous, the ſtandard broad and heart-ſhaped; the wings oblong and plane; and the keel long and erect. STAMINA, ten diſtinct filaments, and ſimple antheræ. PISTILLUM, an oblong germen, ſimple ſtyle, and hairy ſtigma. PERICARPIUM, a large oblong pod, containing kidney-ſhaped ſeeds.

The ſpecies are,

1 ANAGYRIS *Fœtida.*

*Common Stinking Anagyris.*] Anagyris with oval leaves and ſpikes of flowers, proceeding from the ſides of the branches.

2 ANAGYRIS *Creticum.*

*Cretan Stinking Anagyris.*] Anagyris with oblong leaves and longeſt ſpike of flowers.

Theſe ſhrubs riſe eight or ten feet in height, decorated with ſimple, alternate, hoary leaves, and numerous bright yellow butterfly-ſhaped flowers, diſpoſed in long hanging ſpikes, ariſing from the ſides of the branches in May and June, but rarely perfect good ſeeds in England.

They are exotics of Spain, Italy, and the Archipelago Iſlands, but proſper here in the full ground.

The propagation may be effected both by ſeed and layers.

The ſeed is procured from abroad by the nurſery-men and ſeeds-men, which ſhould be ſown in a bed of light earth in March, and the plants will appear in May; give occaſional waterings in ſummer, and ſhelter the firſt winter from ſevere froſt; in March following plant them out in rows, and in two, three, or four

four years they will be of due ſize for the ſhrubbery.

ANANAS, the Pine-Apple. See BROMELIA.

ANASTATICA, Roſe of Jericho.

This is a very low buſhy annual, adorned with oval leaves and ſmall whitiſh flowers, of four petals, diſpoſed in ſhort ſpikes.

Claſs and order, *Tetradynamia Siliculoſa.*

This plant has great ſingularity, which is, that in autumn, when it begins to decay, it contracts itſelf; and if then taken up and preſerved in a dry place till next year, nay for many years, then placed in warm water, it will expand as in its natural growth.

It is raiſed from ſeeds in March or April, in a hot-bed, and in May the plants may be potted and placed in the full air; they will flower in June, and, with occaſional ſhelter of a frame, will perfect ſeeds in autumn.

ANCHUSA, Bugloſs.

There are eight or nine ſpecies, all of which are herbaceous, chiefly perennial, and of hardy growth; ſome grow erect, others trail, garniſhed with rough ſimple leaves, and monopetalous funnel-ſhaped flowers, four or five of which merit culture, ſome as ſalutiferous medical plants, others for ornament.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is acutely five-parted, and permanent. COROLLA, monopetalous, funnel-ſhaped, and five-parted at the brim. STAMINA, five ſhort filaments, and incumbent antheræ. PISTILLUM, four germina, a filiforme ſtyle, and obtuſe ſtigma. PERICARPIUM none, the four ſeeds being lodged in the calix.

The ſpecies of moſt note are,

[1] ANCHUSA *Officinalis.*

*Common Officinal Bugloſs.*] Anchuſa with erect ſtalks, ſpear-ſhaped leaves, and imbricated ſpikes of flowers.

*Varieties of this.*] Common Bugloſs with blue flowers.—Common Bugloſs with white flowers.—Common Bugloſs with red flowers.

[2] ANCHUSA *Sempervivens.*

*Ever-green broad-leaved Bugloſs.*] Anchuſa with trailing branches, broad leaves, two leaves on the pedunculuſes, and ſhort ſpikes of blue flowers.

[3] ANCHUSA *Orientalis.*

*Eaſtern Yellow Bugloſs.*] Anchuſa with trailing branches, hairy woolly leaves, the branches and flowers growing alternately, and oval bractæ on the ſpikes between the flowers.

[4] ANCHUSA *Virginiana.*

*Virginian ſmall Yellow Bugloſs.*] Anchuſa with a low ſmooth ſtalk, and bright yellow flowers, placed in looſe ſpikes.

All theſe are herbaceous perennials, that proſper in almoſt any ſoil and expoſure, though they are of longeſt duration in dry ſoils.

The two firſt ſorts grow naturally in Britain, but all the others are of foreign growth.

The roots of all the ſorts are fibrous.

The ſtalks and branches are round, thick, and moſtly very rough and hairy, decorated with ſimple, oblong, very rough leaves, placed alternate; and numerous flowers, collected into cluſters and ſpikes, ornament the upper parts, each ſeparate flower formed of one infundibuliforme or funnel-ſhaped petal, having a long tube below, and a ſpreading brim, appearing, in the different ſpecies, in ſpring, ſummer, and autumn, and continue in long ſucceſſion on the ſame plant, which, in all the ſorts, are ſucceeded by abundance of ſeed in autumn.

The *Anchuſa Officinalis*, and reſpective varieties, obtain two feet in height, ſending forth many ſide ſhoots, and a numerous ſucceſſion of flowers in June and July.

The Evergreen Bugloſs and *Oriental Anchuſa* extend their branches upon the ground, which furniſh a ſucceſſion of flowers moſt of the ſummer months, and the former often continues in bloom from May till Chriſtmas.

The *Virginian Anchuſa* is a very low plant, but is valuable for its producing numerous flowers early in ſpring.

*Uſes in Gardens, Propagation, &c.*

In reſpect to their uſes in gardens, the Common Bugloſs is eſteemed principally for its medical properties; but all the varieties may alſo be employed with the other ſpecies as plants of ornament, for the embelliſhment of the compartments of large gardens, where many plants of eaſy culture are required; where, though the flowers poſſeſs no remarkable beauty, they will appear conſpicuous enough to encreaſe the variety.

All the ſorts love a dry ſoil, for though they grow ſtrongeſt in moiſt rich land, yet their duration in ſuch ſoils is rarely more than two or three years.

The propagation of all the ſorts is by ſeed, in autumn or ſpring, in a bed of light earth, and in May, June, or July, the plants will be large enough for tranſplantation into the places where they are finally to remain.

All the ſorts riſe freely from the ſcattered or ſelf-ſown ſeeds.

ANDROGYNA *Planta*, (from a man and a woman.) By botaniſts a plant is termed Androgynous, which produce both male and female flowers on the ſame root; the cucumber, melon, gourd, &c. and of trees, the oak, platanus, cheſnut, walnut, mulberry, birch, hornbeam, hazel, &c. furniſh examples. See *Maſculus Flos*, *&c.* Androgynous plants conſtitute the claſs *Monoecia* of Linnæus. See MONOECIA.

ANDROMEDA.

The plants of this genus are principally of the tree and ſhrub kind, moſtly deciduous, hardy, and of moderate buſhy growth, adorned with ſimple alternate leaves, and ſmall monopetalous bell-ſhaped flowers, in ſpikes, or cluſters.

Claſs and order, *Decandria Monogynia.*

*Characters* ] CALIX is acutely five-parted, coloured, and permanent. COROLLA, one bell-ſhaped petal, cut into five reflexed ſegments. STAMINA, ten ſhort filaments affixed to the corolla, and two-horned antheræ. PISTILLUM, a roundiſh germen, long permanent ſtyle, and obtuſe ſtigma. PERICARPIUM, a pentagonal capſule of five cells, containing many roundiſh ſeeds.

The ſpecies are,

[1]ANDROMEDA *Arborea.*

*Tree Andromeda, or Carolina Sorrel-Tree.*] Andromeda with oblong, oval, pointed, alternate leaves, roundiſh-oval greeniſh flowers, diſpoſed in long naked ſpikes, proceeding from the ſides of the branches.

[2]ANDROMEDA *Paniculata.*

*Paniculate-ſpiked Virginia Andromeda.*] Andromeda with oblong, crenated, alternate leaves, and cylindrical yellowiſh flowers, in branching naked ſpikes at the ends of the branches.

[3]ANDROMEDA *Mariana.*

*Maryland Aggregate Andromeda.*] Andromeda with oval entire leaves, placed alternate, and greeniſh flowers, collected in aggregate bunches.

[4]ANDROMEDA *Calyculata.*

*Caliculate Box-leaved, Canada Andromeda.*] Andromeda with obtuſe, ſpear-ſhaped, punctured, alternate leaves, and cylindrical white flowers, diſpoſed in ſhort leafy ſpikes at the ends of the branches.

*Variety.*] Caliculate oval-leaved, evergreen Andromeda.

[5]ANDROMEDA *Racemoſa.*

*Racemoſe-ſpiked Penſylvania Andromeda.*] Andromeda with oblong ſerrated leaves, and cylindrical ſwelling flowers, in cluſtered bractæal ſpikes.

Theſe plants are natives of North America, where they grow naturally in marſhy or boggy places; the firſt of which is ſomewhat impatient of ſevere froſt, but all the others are very hardy, and proſper beſt in moiſt ſituations.

The tree *Andromeda* riſes ten or fifteen feet in height, the branches ſlender and drooping; this is ſomewhat tender; ſo ſome plants ſhould be retained in pots to be ſheltered in winter.

The *Andromeda Paniculata* is a ſhrub of three or four feet ſtature, and ſends forth many branches.

The other three ſpecies are low buſhy ſhrubs, rarely exceeding two feet in height.

All theſe ſhrubs flower here annually in June and July, but they rarely ripen ſeed in theſe parts.

*Uſes, Propagation, &c.*

With reſpect to the utility of theſe ſhrubs in gardens, the firſt ſort is admitted principally among the green-houſe plants, and delights in moiſture; the other ſorts may be admitted to encreaſe the variety in the ſhrubbery; but they ſhould have a moiſt ſoil, otherwiſe they will not proſper in ſummer.

The propagation of all the ſpecies may be effected by ſeed, which is imported by the ſeedſmen annually from America, which muſt be ſown in ſpring in a bed of moiſt earth.

They may alſo be encreaſed by layers in autumn.

All the ſhrub kinds may alſo be propagated by ſuckers, which they ſend up pretty plentifully every year from the roots.

ANGIOSPERMIA, the name of the ſecond of the two orders in the claſs *Didynamia* of Linnæus. See DIDYNAMIA.

The eſſential character of this order is, that the ſeeds of the reſpective plants included therein are lodged in a pericarpium, i. e. a veſſel or pod, which diſtinguiſhes it from the other order *Gymnoſpermia*, of the ſame claſs, where the ſeeds are placed naked in the bottom of the calix. See GYMNOSPERMIA.

ANEMONE, including the Pulſatilla, or Paſque-Flower, and the Hepatica.

It will ſeem ſtrange to ſome to ſee the Pulſatilla and Hepatica retained as ſpecies of the Anemone, which were formerly ranged as diſtinct genera, but late improvements in botany have proved their general characters to be

be the ſame, and proclaim them all relations of the ſame family, and as ſuch we muſt treat of them, though, as they differ extremely in their general appearance, as alſo in their culture, we, for diſtinction ſake, will exhibit them in ſeparate diviſions, under the generical name Anemone. See ANEMONE-PULSATILLA, and ANEMONE-HEPATICA.

Claſs and order, *Polyandria Polyginia.*

*Characters*] CALIX none. COROLLA, ſix or nine petals, diſpoſed in two or three ſeries. STAMINA, numerous capillary ſhort filaments, and double antheræ. PISTILLUM, numerous germina collected into a head, pointed ſtyles, and obtuſe ſtigma. PERICARPIUM none; the ſeeds, which are numerous, reſt on the receptacle, and form an obtuſe cone.

The above characters is applicable, not only to the ſpecies commonly conſidered as Anemones, but alſo to the Hepatica and Pulſatilla.

*Firſt Diviſion.*

In this diviſion we will exhibit only all thoſe ſpecies commonly called Anemones.

The ſpecies are,

[1]ANEMONE *Coronaria, Anguſtifolia.*

*Narrow-leaved coronated Garden Anemone.*] Anemone with the radical leaves divided and ſubdivided by threes, into many narrow ſegments, and a leafy involucrum.

*Varieties.*] The varieties, in reſpect to the colour and variegation of the flowers, are innumerable; but the principal plain colours are, red, blue, crimſon, purple, aſh-colour; and the variegations are, red and white, roſe and white, blue and white; red and white and purple, with innumerable intermediate ſhades; and with ſingle and double flowers, of every colour and variegation.——Proliferous narrow-leaved Anemone, one flower growing out of another.

[2]ANEMONE *Hortenſis, Latifolia.*

*Broad-leaved Garden Anemone.*] Anemone with digitate or hand-ſhaped fingered leaves, having broad ſegments.

*Varieties.*] Flowers of many colours and variegations.

[3]ANEMONE *Nemoroſa.*

*The Wood Anemone.*] Anemone with leaves divided by threes, having the ſegments deeply cut, and one flower on the ſtalk.

*Varieties.*] Common Wood Anemone with ſingle white flowers.—Double white Wood Anemone.—— Purple-wood Anemone.—Double purple Wood Anemone.—Reddiſh-purple Wood Anemone.

[4]ANEMONE *Apennina.*

*Apennine Blue Wood Anemone.*] Anemone with ternate divided leaves, having the ſegments deeply cut, and numerous ſpear-ſhaped petals to the flower.

*Varieties.*] Common Apennine Wood Anemone, with ſingle blue flowers.—Double blue Apennine Wood Anemone.—Violet-coloured Apennine Wood Anemone.—Double violet-coloured Apennine Wood Anemone.

All theſe ſpecies and reſpective varieties are hardy herbaceous perennials, that will proſper in any common ſoil of a garden, either in beds ſeparately, or in the borders among other plants of the flowery tribe.

They are perennial in root, but annual in leaf and ſtalk, which riſes in ſpring, and periſh to the ground when they have flowered and perfected ſeeds.

The roots are tuberous, knobbed, ſolid, fleſhy, and firm; the leaves riſe on foot-ſtalks directly from the root, which, in all the ſorts, are ſimple, but are cut into many narrow parts, the diviſions being generally by threes; and between the leaves riſes the flower-ſtalk, from five or ſix inches to one foot in height, ſurmounted each by one flower, which ſtands naked without any cup, which, in the ſingle kinds, have generally from ſix to twelve petals, but in the double ſorts the petals are of an indeterminate number, which are often ſo numerous and full, as to exclude the parts of fructification; but the ſingle and half-double kinds afford plenty of ſeed annually.

*General Deſcription of the Garden kinds.*

The two firſt ſpecies, *Anemone Coronaria*, and *Anemone Hortenſis*, are the Eaſtern or Garden Anemones, and the parent plants of all thoſe numerous beautiful different coloured ſingle and double varieties that adorn our gardens in ſpring, and beginning of ſummer; they are originally natives of the Levant, and other parts of the Eaſt; but grow freely with us in the full ground, with little trouble, in beds or borders, and furniſh an annual ſucceſſion of their beautiful flowers ſix weeks or two months, and perfect abundance of ſeed annually, and their roots multiply exceedingly.

Their roots, as before hinted, are tuberous, knobbed, irregular, and formed into unequal knobby heads.

The leaves are ſimple, large, and decompound, which, in the firſt ſort, *Anemone Coronaria*, and all its varieties, are deeply di-

vided into many ſegments, and theſe again ſubdivided into numerous narrow diviſions; ſo, for diſtinction, this ſpecies is called Narrow-leaved Anemone. The ſecond ſort, *Anemone Hortenſis*, and varieties, has alſo large, ſimple, decompound leaves, which are digitate or fingered, but the diviſions are not ſo deep, and the fingers or ſegments being broader than thoſe of the former, it is called Broad-leaved Anemone.

The flower-ſtalk of both ſpecies, and reſpective varieties, riſe between the leaves directly from the roots, frequently two, three, or more, from the ſame root, and obtain from about eight or nine to ten or twelve inches in height, and a little above its middle grows a leafy appendage, called the involucrum, and at top ſtands one large conſpicuous flower, which, in ſome varieties, is as large as a double roſe. In their ſingle ſtate the flowers have only ſix or nine petals, but in the double kinds they are innumerable: ſix large petals compoſe the outward part; in the midſt ſtand numbers of ſmaller ones, in a great many circular ſeries, filling up the body of the flower in a globular tuft, which, by floriſts, is called the thrum.

In the ſingle and half-double kinds riſe a vaſt cluſter of thread-like ſtamina, and in the centre of theſe are the rudiments of the ſeed, formed in a ſmall roundiſh head.

But in the full double flowers, all thoſe parts of fructification are often entirely obliterated by the multiplicity of the petals, ſo that the ſeeds are to be expected principally from the ſingle and ſemi double flowers.

The common ſingle kinds, i. e. with ſix or nine petals, with the cluſter of filaments in the middle, are commonly called Poppy Anemones, from their ſimilarity to a ſingle poppy.

*General Deſcription of the Wood Anemones.*

The third and fourth ſpecies, *Anemone Nemoroſa*, and *Anemone Apennina*, grow wild in woods in this country, particularly the former, which is found plentifully in many parts of the kingdom, in their ſingle ſtate; but the double ſorts of them have been obtained by culture in gardens from the ſeeds of the ſingle kinds.

The roots of both theſe and varieties, are fleſhy, oblong, and irregular; run under the ſurface, and ſend forth many fibres.

The leaves riſe from the root on long foot-ſtalks; they are pretty broad, and divided into three principal parts, and theſe again deeply cut on the edges.

The flower-ſtalk riſes from ſix to eight or nine inches high, having a leafy involucrum, and each ſtalk crowned by one pretty large flower, which, in its ſingle ſtate, have generally ſix pretty broad petals, in two ſeries, with a cluſter of ſtamina, and a head of rudiments of ſeeds in the centre; but the double flowers have innumerable ſmall looſe petals, forming a globular head, and are very pretty.

*Uſe in Gardens of all the Sorts.*

The two firſt ſpecies, and their numerous train of varieties, are very pretty ornaments for the flower-garden, and the double kinds have ſuperior beauty; the varieties in general are curious furniture for embelliſhing the fronts of the principal compartments of the pleaſure ground, as they will proſper in the common open borders, &c. in which they have a fine effect, when properly diſpoſed in aſſemblage with plants of ſimilar growth and times of flowering, for they blow freely in any common light earth, and nothing injures them but overabundant moiſture of ſoil; and ſometimes late froſts in April and May deface the thrum that compoſe the middle of the flower, but this is ſeldom.

However, as the capital ſorts are often procured at a great price, and ſome are of ſingular beauty, it is eligible to plant the beſt of them ſeparate in narrow beds, in order, that when the plants begin to ſhew bloom, they may be arched over to be covered with garden mats, when cutting winds and froſts prevail.

But I ſhould adviſe to plant many of the common kinds in the open borders, towards the front, in ſmall cluſters, of three, four, or five in each; in which order the flowers will be very ſhowy, and produce a fine variety for ſix weeks or two months.

The principal ſeaſon of flowering of all the double varieties is April and May, but by planting the roots at different times in autumn and ſpring, the bloom may be continued from March until the middle of June.

The broad-leaved kinds are generally the hardieſt blowers, and if ſome are planted late in March, in a ſomewhat ſhady border, they will exhibit a bloom in July.

All the choice double kinds ſhould be taken up annually when the flower is paſt, in order to ſeparate the encreaſed parts or offſets which ariſe from the ſides of the main roots, and which, if taken up juſt after the flower fades, may be retained out of ground

ſeveral

ſeveral months, and planted according to the time you deſign they ſhall blow.

The Single or Poppy Anemone comes very early into bloom, often in January and February, and its flower, though compoſed but of ſix petals, is large and ſhowey, and is worthy of a place in the common borders, which, if diſpoſed four or five together in patches, alternately with bunches of ſnow-drops, crocuſſes, winter aconites, hepaticas, and Chriſtmas roſes, they will exhibit a fine variety at an early ſeaſon, and the roots may be permitted to remain two or three years unremoved.

The Wood Anemones are fine furniture for the borders of wood-walks, the fronts of ſhrubbery clumps, and for wilderneſs works, and in ſhort, for any other compartments where a variety of early bloom is required, for they will ſucceed any where.

*Method of Planting the Garden Kinds.*

The roots of all the varieties of the two ſpecies of Eaſtern or Garden Anemone, are ſold by the nurſerymen, and at moſt of the ſeed-ſhops. The fine double varieties are generally imported from Holland, which are ſold by the hundred, &c. The common kinds, both double and ſingle, by the pound weight.

The Dutch ſorts are per hundred from eight or ten ſhillings to ſo many guineas, which however is more than they are worth.

The common double Engliſh kinds are ſold per lb. from five to ten or twelve, and the ſingle or Poppy Anemonies from three to five ſhillings.

The ſeaſon for planting all the above varieties, is according to the time it is deſigned they ſhall flower.

The beſt time to plant the principal ſorts for the general bloom is October, or early in November, and the plants will come into flower in April and beginning of May; but if ſome are planted in the middle of September, and a ſecond parcel towards the middle or latter end of October, both plantations will afford a ſucceſſion of bloom from the beginning of April until the middle of May; and if a third plantation is made in February or beginning of March, they will come into flower about the middle of May, and continue until the middle of June, whereby the bloom may be continued near three months.

In reſpect to the above times of planting theſe roots, obſerve, that thoſe planted early in autumn come up in leaf before Chriſtmas, and they always produce the largeſt flowers, and continue longeſt in beauty; the roots too will be better nouriſhed, and afford a larger encreaſe than thoſe planted in ſpring.

It is however neceſſary always to retain ſome out of ground till ſpring, for the ſake of a ſucceſſion of bloom.

The ſituation proper for the Anemone ſhould be free from copious moiſture, and the expoſure ſhould be open to the ſouth ſun and free air, and unincumbered by the ſhade of trees, which ſhould be particularly obſerved for the blow of the capital kinds.

In regard to ſoil, the Anemone will proſper and flower in tolerable perfection in any common moderately light earth of a garden, only obſerving to avoid planting them in over-moiſt and ſtiff ſoils, which would rot the roots in winter; and if any augmentation is neceſſary to raiſe or form the beds or borders for their reception, no more is needful than common light mould from the quarters of the kitchen garden, or any other well-wrought garden earth, working the whole one good ſpade deep.

Profeſſed floriſts, however, in order to blow the capital ſorts in their ultimate ſtate of beauty, often prepare compoſts of different ingredients wherewith to form beds for the reception of the roots.

The beſt is that of freſh earth from a paſture, neats dung, and ſea-ſand. Take maiden loamy earth from the ſurface of a common or other paſture field, the top-ſpit turf and all; to every load of this add one of neats dung, and half a one of ſea or drift-ſand; blend the whole together, and form it in a ridge, in which let it remain a year at leaſt, turning it over every two or three months; (ſee COMPOSTS.) But in default of paſture earth, a good compoſt may be formed of common light garden mould, and rotted neats dung, adding to every load of the former half a one of the latter, and about a quarter of that of driſt or ſea-ſand; and of either of which compoſts the bed is to be formed, about twelve or fifteen inches in depth, and three and a half broad.

The mode of planting is to be obſerved according to the following rules.

If it is deſigned to plant any of the common double and ſingle kinds in the borders, in aſſemblage with other plants, I ſhould adviſe to plant them in patches, that is, to plant three, four, or five roots together, in a patch of five or ſix inches breadth, putting them two or three inches deep; and thoſe

patches

patches may be five, ten, or fifteen feet diſtance, ſome near the edge, others more towards the middle; in which order they will make a pretty appearance.

But when it is deſigned to plant them, in the floriſt's way, in beds by themſelves, they muſt be planted in continued ranges, lengthways.

The beds for this purpoſe are to be marked out three feet and half broad, the length at pleaſure, with alleys eighteen inches wide between bed and bed. The beds muſt be worked or prepared one full ſpade, or fifteen or eighteen inches deep; break the earth ſmall, but do not ſift it, obſerving, that to prevent lodgment of wet, and to give the beds a good appearance, as well as to ſhew the flowers to the beſt advantage, it is eligible to elevate them three inches above the common level or general ſurface; but if there is danger of moiſture ſtanding in winter, double or treble that is proper height, working the whole a little rounding, and rake the ſurface ſmooth; then put in the roots.

In each bed plant ſix rows lengthways, the roots at ſix inches diſtance in each row, and two or three inches deep; and when one bed is planted, run over it lightly with the rake, to reform all inequalities, and make the ſurface ſmooth.

The roots being planted, thoſe of the autumn plantation will come up in leaf in November, but as the plants are hardy, nothing is needful to be done till the bloom begins to appear; and then, if you think proper, to beſtow a little care upon the capital ſorts, by arching the bed with hoops, in order to cover the bloom with mats occaſionally, to protect it from cutting black froſts, which often prevail in April.

To produce a very early bloom of any kind of Anemone, plant ſome roots in pots in October, and towards Chriſtmas place them either in a hot-houſe, or upon a common hot-bed, under frames and glaſſes.

*Their Propagation.*

All the varieties are propagated by off-ſets from the root, and new varieties are obtained from ſeed.

But firſt of propagating them by parting the off-ſets.

By off-ſets, all the kinds encreaſe exceedingly every year; ſo the roots of all the capital kinds, at leaſt, ſhould be taken up annually at the decay of the leaf, and the root may be divided or broken into as many pieces or knobs as are furniſhed with an eye or bud, and every ſuch part will readily grow, and produce a flower exactly like that of the parent root the ſpring following; obſerving however, that if they are divided very ſmall, they flower very weak the firſt year; therefore, if you would have ſtrong flowers from the main root, only break off thoſe ſmall ones that are ſlightly affixed thereto; but they ſhould not be thus divided until autumn, or near the time for planting them again.

The time for taking up the roots is in May and June, when the leaf and ſtalk are withered, for then the roots ceaſe to grow for a month or ſix weeks; but if they are permitted to ſtand to put forth freſh fibres again, they ſhould not be removed that ſeaſon.

They ſhould be taken up in dry weather, and ſpread in an airy place out of the ſun, about a week, then cleared from earth, and put up in bags or boxes till the planting ſeaſon arrive.

The above work ſhould always be performed annually to the capital kinds, both for the ſake of increaſe, and to freſh dig and prepare the beds.

By propagation by ſeed all the beautiful varieties were, and continue annually to be obtained.

The proceſs is not very tedious, for the plants will flower the ſecond or third year.

The ſeed may be had at the ſhops; but if you ſave it yourſelf, it ſhould be from the beſt ſingle or ſemi-double flowers; the full doubles afford none. The time to ſow it is March, either in boxes, large pots, or wide earthen pans, of perfectly light compoſt, or in a bed of ſuch earth; ſow it moderately thick, and cover it near a quarter of an inch deep with ſifted mould: from this time occaſional ſhade from the ſcorching ſun, and moderate waterings in dry weather is neceſſary, and in ſix weeks the plants will appear, keeping them clear from weeds; and when the leaves decay, ſift a quarter of an inch of earth over the bed, which is all that is neceſſary till the ſecond ſummer, when they are to be taken up at the decay of the leaf, and managed as the old roots in the manner already directed, and next ſpring they will flower and diſcover many new beauties, and among them many that are very ordinary, which will do for the common borders.

The propagation of the Wood Anemone is by dividing the roots any time after the decay of the leaves in June until October, though the ſooner after the fall of the leaf the better.

At which time the common ſorts may be tranſplanted from the woods.

The other ſpecies of leſs note are,

[1]ANEMONE *Virginiana.*

*Virginian Wood Anemone.*] Anemone with a branching ſtalk, producing long alternate flower-ſtalks, ſmall whitiſh flowers, and cylindrical ſpikes of hairy ſeeds.

[2]ANEMONE *Dichotoma.*

*Forked-ſtalked Canada Anemone.*] Anemone with a forked ſtalk, trifid cut leaves, ſitting cloſe, growing oppoſite, and embrace the ſtalk.

The firſt grows a foot high, the other almoſt double that height; the flowers are white, ſmall, and of no great beauty. They may be raiſed from ſeed, or by dividing the roots.

*Second Diviſion of Anemone.*

ANEMONE-PULSATILLA, the *Pulſatilla* or Paſque-Flower.

Claſs, order, and characters, the ſame as the Anemone.

The *Pulſatilla* has been always conſidered as a diſtinct genus, till the Linnæan botany juſtly declared all the ſorts ſpecies of the Anemone.

The plants are herbaceous, hardy perennials, of the flowery tribe, that produce annual ſtalks ten or twelve inches high, each ſurmounted by one large flower, bearing great reſemblance to thoſe of the Anemone kind, which make a good appearance in the common borders.

The ſpecies are,

[1]ANEMONE-PULSATILLA *Vulgaris.*

*Common large Pulſatilla or Paſque-Flower.*] Anemone-Pulſatilla with divided and ſub-divided pinnated leaves, having a leafy involucrum, nodding flower, and erect petals.

*Varieties of this are,*] Common Pulſatilla with ſingle blue flowers ——with double blue flowers —— with ſingle and double white flowers —— with ſingle and double red flowers——with violet-coloured flowers —— and with flowers having fringed petals.

[2]ANEMONE-PULSATILLA *Patens.*

*Spreading-flowered Siberian Pulſatilla.*] Anemone-Pulſatilla with digitate, many-pointed, downy leaves, and upright pale yellow flower with ſpreading petals, and deep yellow ſtamina, and with the involucrum at a diſtance from the flower.

[3]ANEMONE-PULSATILLA *Vernalis.*

*Early Smallage-leaved Alpine Pulſatilla.*] Anemone-Pulſatilla with ſimply pinnated leaves, and erect bright yellow flowers.

The plants are perennial in root, but annual in leaf and ſtalk, which come up in ſpring, and periſh in June or July, when they have flowered and perfected ſeeds.

The roots are long, thick, fleſhy, and of downright growth.

The leaves riſe immediately from the root, on foot-ſtalks, and are decompounded into many very narrow ſegments.

The flower-ſtalk riſes annually between the leaves, eight, ten, or twelve inches in height, often ſeveral from the ſame root; near the top of each is the leafy many-pointed involucrum, ſerving as a kind of flower-cup, and at top ſtands one large bell-ſhaped flower, in magnitude equal to a large ſingle Anemone, is compoſed of ſix petals, in two ſeries, with a cluſter of ſtamina in the middle; but in the double flowers the petals are numerous.

They flower in March and April, and the ſeeds ripen early in autumn.

The Common Pulſatilla grows wild on hills, heaths, and dry paſtures in Britain, and other parts of Europe, and the others are natives of the Siberian and Alpine mountains, but they have been long inhabitants of many curious gardens.

The plants are good furniture for the common borders, particularly the firſt ſpecies and reſpective varieties, and they proſper any where.

The propagation of all the three ſpecies is effected by ſeed, and by dividing the roots. The ſeed ripens in July, and may be ſown ſoon after, or early in ſpring, in a bed of light earth.

The propagation by roots is this: take up ſome of the large roots in July, when their leaves decay, or even any time till October, and ſuch of them that are grown into heads, may be divided into as many parts as have a bud or head at top, which plant, and they will each flower the following ſpring.

The proper time of year to remove thoſe roots, is any time from the decay of the leaf until Michaelmas.

The roots do not bear to be kept long out of ground.

*Third and laſt Diviſion of Anemone.*

ANEMONE-HEPATICA, the Hepatica, or Noble Liverwort.

Claſs, order, and characters, the ſame as the Anemone. See ANEMONE.

As the Hepatica, in point of general habit, having been always conſidered as very different from the Anemone, we, for the greater facility of diſtinction, treat of it in a ſeparate diviſion, obſerving however that the whole flower,

flower, though conſiderably ſmaller, poſſeſſes all the characters of the Anemone; although it was long conſidered as a diſtinct genus, principally from the trefoliate appendage ſituated near the flower, being miſtaken for a calix or cup; but Linnæus conſiders that only as a three-leaved involucrum, common to all the Anemone kind, for there is no calix. See the *Characters*.

There is but one ſpecies of Hepatica, of which are many varieties, all very low, herbaceous, flowery perennials, that adorn our gardens in early ſpring, each with a large tuſt of numerous flowers.

The ſpecies is,

ANEMONE-HEPATICA, *Hepatica*.

*The Hepatica.*] Anemone with leaves compoſed of three roundiſh undivided lobes, and the involucrum ſituated near the flower.

*Varieties of this are,*] Hepatica with ſingle and double blue flowers ——with ſingle and double red flowers ——with ſingle and double red and white flowers ——with violet-coloured flowers ——with ſingle and double white flowers—and Hepatica with ſtriped leaves.

Theſe plants form themſelves into low roundiſh bunches; the whole, including leaves, flower-ſtalks, and flowers, never exceed five or ſix inches in height, which are annual, but the root is of many years duration.

The root is thick, formed into heads, and hath numerous matted fibres.

The flowers appear before the new leaves, but thoſe riſe immediately after, the whole riſing directly from the root; the flower-ſtalks are ſlender, four or five inches high, and riſe in great numbers, each ſupporting one ſmall flower, which, in its ſingle ſtate, hath ſix petals; but theſe are numerous in the double flowers, and in all the varieties, they ſtanding in vaſt cluſters make a beautiful appearance in February, March, and April, ſucceeded in the ſingle kinds by plenty of ſeed in ſummer.

All the varieties are choice furniture to adorn the fronts of borders, and other compartments contiguous to the habitation.

The double kinds have the greateſt merit, the flowers being larger, and continue longer in bloom, and ſhould occupy the moſt conſpicuous places; but as theſe can only be encreaſed by dividing the roots, which being remarkably ſlow of growth, are not ſo eaſily acquired as the ſingle kinds, which may be raiſed plentifully from ſeed.

The propagation of the ſingle kinds is effected both by ſeed and parting the roots, but the double ſorts only by the latter method.

Obſerve however, that from ſeed of ſingle flowers double ones are often obtained.

The ſeed may be ſown in Auguſt, September, or March, in a bed or border of light earth, covering it hardly a quarter of an inch deep, and the plants will appear in April and May; give occaſional water and weeding, and in Auguſt or September prick them upon a border open to the morning ſun, where they will flower in ſpring, and in a year after tranſplant them where they are to remain.

Thoſe plants being very ſlow in growth, it will be three years before they form large bunches, ſo as to produce tolerable cluſters of flowers.

The propagation by parting the roots is performed in ſpring; divide each root into two, three, or more parts, but not too ſmall, becauſe of their reluctant growth; for the merit of the plants is to have them form large bunches, capable of producing fifty or ſixty flowers on the ſame root, which, ſtanding in a compact cluſter, make a beautiful appearance.

The ſeldomer theſe plants are removed, the ſtronger and more numerous will be their flowers.

ANETHUM, Dill, Fennel, and Finochia.

The plants are herbaceous; there are three ſpecies, all well known umbelliferous herbs of the kitchen garden.

Claſs and order, *Pentandria Digynia*.

*Characters.*] CALIX, the flowers are umbellated, and the umbels are compound, have neither calix nor involucrum. COROLLA, the general umbel is uniform, and the florets of the umbel have each five petals. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, a germen under each floret, two ſtyles, and obtuſe ſtigmas. PERICARPIUM none, and the ſeeds are two ſucceeding each germen.

The ſpecies are,

[1]ANETHUM *Graveolens*.

*Common Dill, or Rank Anethum.*] Anethum with finely divided leaves, and compreſſed ſeeds, having borders.

[2]ANETHUM *Fœniculum*.

*Common Fennel or Finckie.*] Anethum with decompound leaves, the lobes finely divided, ending in many points, and oval ſeed.

*Varieties*

*Varieties of this.*] Common light-green-leaved Fennel.—Dark-green-leaved Fennel.—Sweet Fennel, with long ſlender ſparſed leaves, and white ſweet ſeed.

[3]ANETHUM *Azoricum.*

*Azorian Dwarf Fennel, or Finochio.*] Anethum with a dwarf ſtalk, ſwelling, and fleſhy near the root, and recurved ſeed.

Theſe plants are all of hardy growth; the Dill and Finochia are univerſally annual; the Fennel and its varieties are annual in leaf and ſtalk, but have perennial roots. The roots are univerſally ſpindle-ſhaped, and grow downright; the leaves are decompound, with the lobes finely divided into numerous, minute, thread-like ſegments; and the flower or ſeed-ſtems riſe from one to five feet high, terminated by the umbels of flowers, ſucceeded by plenty of ſeed in Auguſt and September.

The Dill riſes with a few ſlender leaves, and a ſlender erect ſtem, two or three feet high, the heads or umbels of which, when the ſeeds are formed, are the parts uſed in the kitchen for cucumber pickle, &c. and the ripe ſeeds for medicine.

The *Anethum Fœniculum*, and varieties, hath thick, fleſhy, downright roots, which, after the firſt year, ſend up a great tuft of large leaves, and ſtrong erect ſtems, four or five feet high, dividing into many branches. The leaves are the parts uſed in the kitchen for mackerel, pickled-ſalmon, garniſh to diſhes, &c. therefore, the ſtems of a few plants ſhould be cut down as they advance in ſummer, to procure a ſupply of young leaves from the bottom; but for medical purpoſes, the root, leaves, and ſeed are uſed.

The *Finochio* is a ſallad herb. The plant hath a ſhort robuſt ſtalk, the bottom of which ſwells like a large flat turnip, and this being rendered white and tender by blanching, is the part uſed, which is eaten raw, being ſliced and reliſhed with vinegar, oil, pepper, &c.

*Propagation, Culture, &c.*

They are all propagated by ſeeds, which, of the Dill and Finochio, muſt be ſown annually, becauſe the plants endure but one year.

The Dill and Fennel may be ſown either in autumn or ſpring; the autumn ſowing generally riſe ſtrongeſt, and ſhould be ſown where they are to remain, eſpecially the Dill; they require no particular ſoil or expoſure; ſow the ſeed broad-caſt thinly on the ſurface, and rake it in, and in May or June the plants muſt be thinned by hand or hoe, the Dill to ſix or eight, and the Fennel to twelve or fifteen inches diſtance.

As the Fennel is of ſeveral years ſtanding, it may, for the ſake of regularity, be either ſown as above, or in drills a foot aſunder.

Theſe two ſpecies are remarkable for riſing abundantly from the ſelf-ſown ſeeds, often ſufficient for private ſervice.

The Fennel may alſo be encreaſed by ſlipping the large roots, which frequently divide themſelves into heads; but theſe do not ſucceed ſo well as the ſeedling plants.

The Finochio is ſown in the middle of March, or beginning of April, and to continue a ſucceſſion till winter, repeat the ſowings every month until July. Chuſe an open ſpot of rich light ground, and by line and hoe draw ſhallow drills, two feet diſtance; ſcatter the ſeeds thinly along the bottom, and cover them near a quarter of an inch deep with finely broken mould, and when the plants are an inch or two high, ſmall hoe them to kill weeds, and thin them to three inches, and in two or three weeks after cut them out to treble that diſtance, that the baſe of the ſtem may have room to ſwell.

When the ſtalks are conſiderably ſwelled at bottom, earth them up on each ſide, and in two or three weeks that part will be very white and tender.

ANGELICA.

This genus furniſhes four herbaceous perennials, of large and vigorous growth, obtaining four or five feet ſtature, branching ſtrongly, garniſhed with large pinnated leaves, and ſurmounted by numerous flowers, collected into conſiderable umbels.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, the flower is umbellate, and the umbel is compound; the general umbel has a five, and the partial umbel an eight-leaved involucrum, and the calix of the florets is ſmall and five-parted. COROLLA, the umbel is uniform, and each floret has five petals. STAMINA, five filaments, and ſimple antheræ. PISTILLUM, a germen under each floret, two reflexed ſtyles, and obtuſe ſtigma. PERICARPIUM none, the ſeeds are two, ſucceeding each germen.

The ſpecies are,

[1]ANGELICA *Sativa.*

*Cultivated, or Garden Angelica.*] Angelica with leaves compoſed of lobes, unequal in ſize and number.

[2]ANGELICA *Sylveſtris.*

*Wild Engliſh Angelica.*] Angelica with leaves compoſed of equal ſpear-ſhaped ſerrated lobes.

[3]ANGELICA *Lucida.*

*Shining Canada Angelica.*] Angelica with ſhining leaves, compoſed of equal oval lobes, the edges cut and ſerrated.

[4]ANGELICA *Atropurpea.*

*Dark-purple Canada Angelica.*] Angelica with blackiſh-green pinnated leaves, having the extreme pair of lobes joined.

All theſe plants are perennial in root, but the leaves and ſtalks are renewed annually in ſpring.

The roots are branching and fibrous.

They ſend up robuſt and ſtrongly branching ſtalks, four or five feet high, adorned with large pinnated leaves, compoſed of ſeveral large lobes, and the ends of all the ſtalks and branches are terminated by large compound umbels of flowers, ſucceeded, in all the ſpecies, by abundance of ſeed in Auguſt and September.

The Garden Angelica is in great requeſt for its efficaceous properties in medicine; and of its young tender ſtalks in May, cut into many pieces, is made an admirable ſweetmeat. As a garden plant it is ſometimes admitted in large pleaſure grounds, to encreaſe the variety, where it cuts a tolerable figure, with its large branching head, conſiderable foliage, and vaſt umbels of flowers.

The *Angelica Sylveſtris* grows wild by river ſides and moiſt places, and having little merit, is rarely admitted in gardens, unleſs merely for obſervation.

The two Canada ſpecies poſſeſs little virtue or beauty; but being foreigners, and for the ſake of variety, are allowed places in many of our gardens, in large grounds, where many plants of eaſy culture are required.

All theſe plants delight in moiſture, but they rarely diſdain any ſoil or ſituation.

*Propagation.*

All the ſorts may be raiſed with facility from ſeed, in a bed or border of common earth.

The time of year to ſow them is either in autumn, i. e. September or October, or early in ſpring, obſerving the autumn ſowing generally riſe ſtrong and regular in ſpring following, and thoſe ſown in ſpring ſometimes riſe ſtraggling, ſo ſhould be ſown conſiderably thicker.

The method of ſowing this ſeed is by broad-caſt on the ſurface, and rake it in.

When the plants are four or five inches high, tranſplant them into a bed or border of moiſt earth, fifteen or eighteen inches diſtance, and give occaſional waterings; and if any are required in the pleaſure ground for variety, tranſplant them from the above bed in ſpring following.

Theſe plants produce only leaves the firſt year; the ſecond they ſhoot up ſtalks, flower, and perfect ſeeds.

Obſerve, that when the firſt ſtems of thoſe plants are permitted to perfect ſeeds, the roots frequently periſh in winter, in which caſe a ſupply muſt be raiſed annually; but if the ſtems are cut down in June, it encreaſes the root, and it will ſurvive ſeveral years.

ANNONA, *Guanabus*, or Cuſtard-Apple, and Papaw-Tree.

The plants are of the tree and ſhrub kind; there are ſeven or eight ſpecies, one of which is a hardy deciduous ſhrub, the others moſtly ever-green, and of the ſtove temperament; all the ſorts are adorned with ſimple leaves, and bear large roundiſh and oblong fruit.

Claſs and order, *Polyandria Polygynia.*

*Characters.*] CALIX, five heart-ſhaped leaves. COROLLA, ſix petals, the three outermoſt the largeſt. STAMINA, the filaments hardly viſible, but numerous antheræ. PISTILLUM, a roundiſh germen placed under the flower, inviſible ſtyles, having many obtuſe ſtigma. PERICARPIUM, a large, oblong, oval fruit, of one cell, containing many oval hard ſeeds.

The ſpecies of moſt note are,

[1]ANNONA *Reticulata.*

*Netted-fruited Annona, or Cuſtard-Apple.*] Annona with ſpear-ſhaped pointed leaves, and large, conical, orange-coloured fruit, having a netted rind.

[2]ANNONA *Muricata.*

*Prickly-fruited Annona, or Sour-Sop.*] Annona with oval, ſpear-ſhaped, plane, ſmooth, ſhining leaves, and large oval, greeniſh-yellow, prickly, ſour fruit.

[3]ANNONA *Squamoſa.*

*Scaly-fruited Annona, or Sweet-Sop.*] Annona with oblong-pointed leaves, and ſmall oval, obtuſe, ſcaly, ſweet fruit.

[4]ANNONA *Paluſtris.*

*Marſh Annona, or Water-Apple.*] Annona with oblong, obtuſe, ſmooth, odoriferous leaves, and round ſmooth fruit.

[5]ANNONA *Cherimola.*

*Cherimola Broad-leaved Annona.*] Annona with broad, ſmooth, ſhining leaves, and oblong,

oblong, ſcaly, purple fruit, having a ſoft ſweet pulp.

6 ANNONA *Triloba.*

*Three-fruited Annona, or Papaw-Tree.*] Annona with large ſpear-ſhaped leaves, and inverted pear-ſhaped fruit, growing by threes on each foot-ſtalk.

Theſe trees are natives of America, the firſt five ſpecies that of the warmeſt parts; they are ever-green, and require the conſtant aid of a ſtove in this country. But the ſixth ſort is a hardy deciduous ſhrub, that proſpers here in the full air.

In America, the firſt five ſpecies obtain twenty or thirty feet ſtature, garniſhed with beautiful large leaves, which are univerſally ſimple, and ſtand alternate; and flowers proceeding ſingly from the ſides of the branches, ſucceeded by large fruit, full of a ſoft pulpy ſubſtance, in ſome very ſweet and palatable, that of the *Annona Reticulata* being of the texture of a cuſtard, whence it, in America, derived the appellation of Cuſtard-Apple.

Theſe five ſpecies however never produce fruit in Europe, and rarely flower, ſo are retained here in ſtoves by the curious for variety, and the beauty of their ever-green leaves.

The *Annona Triloba* or Hardy Papaw, is of North America; it riſes twelve or fifteen feet high, the leaves very large and alternate, and the flowers are of a chocolate colour, which ſometimes appear here in May, but never any fruit.

*Propagation, Culture, &c.*

All the ſorts are propagated by ſeed.

The ſeeds are imported from America by many of the London ſeedſmen, &c. they are to be ſown as ſoon as they arrive; thoſe of the tender kind in pots of light rich earth, and plunged in a bark-bed under glaſſes; and when the plants are three inches high, prick them in ſeparate pots, give water, and plunge them in the bark-bed in the ſtove, where they muſt be always retained and treated as other woody plants of that department.

The ſeeds of the hardy Annona may either be ſown in a bed of common light earth, or in pots or boxes, which latter, at the approach of winter, may be moved into the greenhouſe, or ſhelter of a frame, for the plants are impatient of ſevere froſt whilſt young, ſo the ſeedlings ſhould be planted in pots to have occaſional ſhelter the firſt two or three winters, then turned out into the full ground.

If the plants do not riſe the firſt year, plunge the pots upon a hot-bed in ſpring.

ANTHEMIS, Chamomile.

This genus furniſhes upwards of twenty ſpecies of herbaceous plants, conſiſting of annuals and perennials; of which not more than five or ſix merit notice, either for uſe or ornament.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX is hemiſpherical and ſcaly. COROLLA, a compound radiated flower, the diſk or middle compoſed of funnel-ſhaped hermaphrodites, and the radius of flat female florets. STAMINA, five filaments in the hermaphrodite flowers. PISTILLUM, a germen, ſimple ſtyle, and two reflexed ſtigmas. PERICARPIUM none, the ſeeds ſit naked on the receptacle.

The ſpecies of note are,

1 ANTHEMIS *Nobilis.*

*Noble or Common Chamomile.*] Anthemis with pinnated leaves, compoſed of numerous minute, acute-pointed, ſomewhat hairy ſegments.

*Varieties.*] Common Chamomile with ſingle white flowers —with double white flowers —with very large double white flowers.

2 ANTHEMIS *Maritima.*

*Maritime or Sea Chamomile.*] Anthemis with pinnated, fleſhy, indented, dotted, naked leaves, trailing branching ſtalks, and white flowers.

3 ANTHEMIS *Tomentoſa.*

*Downy Grecian Sea Chamomile.*] Anthemis with pinnated, plane, obtuſe, many-pointed, downy leaves, branching ſtalks, and white flowers.

4 ANTHEMIS *Tinctoria.*

*Tinctorated Ox-eye Anthemis.*] Anthemis with tall erect ſtalks, doubly-pinnated ſawed leaves, woolly underneath, and large flowers growing in a corymbus.

*Varieties.*] Common German Ox-eye Anthemis with white flowers.——Great Oriental Ox-eye Anthemis with ſulphur-coloured flowers —— with yellow flowers —— with ſcarlet flowers ——with pale red flowers—— and with large white flowers.

5 ANTHEMIS *Pyrethrum.*

*Pyrethrum or Pellitory of Spain.*] Anthemis with trailing branches, pinnated, finely divided leaves, and each branch terminated by one large flower.

All theſe are hardy perennials, cloſely adorned with numerous pinnated leaves,

finely divided into a multitude of minute parts, and compound radiated flowers, but the radius is not diſtinct in the double kinds.

The *Anthemis Nobilis* is the Odoriferous or Common Chamomile, well known for the medical virtues of its flowers, which are equally efficacious in all its varieties, and the plants merit culture in every garden. The two double kinds merit culture alſo as flowering plants; the common double ſort is well known; its flowers, though ſmall, are perfectly full and pretty; but the large double kind is almoſt three times as big, and are very beautiful.

They are low trailing plants, ſpreading themſelves upon the ſurface of the earth; their branches emitting roots as they advance, and multiply exceedingly, and produce numerous flowers in June, July, and Auguſt, or even till October.

The *Anthemis Maritima* and Downy Anthemis are low, buſhy plants, and produce numerous flowers from July until November, and may be admitted to form variety in the compartments of pleaſure grounds.

The *Anthemis Tinctoria* and varieties are ſpreading plants, and ſend up branching ſtems a yard high, ornamented with corymbuſes of flowers from June until November, and make a good appearance in the ſhrubbery compartments.

The *Pellitory of Spain* hath a carrot ſhaped root, and branches ſpreading a foot each way on the ground, producing large ſolitary flowers in June and July.

The root of this ſpecies afford relief in the tooth-ach.

*Propagation, &c.*

The Common Chamomile and varieties are propagated by parting the roots, and by ſlips and cuttings of their trailing branches.

The beſt ſeaſon for this is March and April, although it may be done in any of the ſummer months. Thoſe intended for medical uſe muſt be planted in a bed or border, in little tufts, nine inches or a foot aſunder; give ſome water, and they will ſoon ſpread and produce plenty of flowers the ſame year.

If the double ſorts are deſigned as flowering plants, ſet them in little bunches in different parts of the borders.

The other four ſpecies are eaſily raiſed from ſeed, in a bed of common earth, in March and April; likewiſe by ſlips and cuttings of their branches, in a ſhady border, any time in ſummer; afterwards tranſplant them into the fronts of ſhrubberies, where they will endure many years, and flower annually.

To this genus belong alſo all the Mayweeds of the fields, having leaves ſomewhat like Chamomile, and white radiated flowers, with yellow middles.

ANTHERÆ, the Apex, Summit, or Top of the Stamina, or Stamen of Flowers, and is elevated by means of the filaments. See STAMEN and FILAMENTUM.

This part of the flower, i. e. Antheræ, is of the utmoſt utility in the generation of plants; for, according to the ſexual ſyſtem, it is the principal part of the male organs, and contains the fecundating *pollen*, or fine and coloured duſt, abſolutely neceſſary for the impregnation of the female parts of the fructification of flowers, to render them prolific or fruitful, and to fertilize the ſeeds, which otherwiſe would prove abortive.

The ſexual ſyſtem being founded on the ſuppoſed impregnation of the ſeeds by the male duſt or powder contained in the Antheræ, the importance of that part of the flower is conſiderably augmented. See SEXUS.

The Antheræ produces, and, when ripe, diſcharges a powder called *pollen*, which falling upon the ſtigma, or female organ, is abſorbed by a tough and viſcid humour, with which the ſurface of that part is covered, and paſſing from thence through the ſtyle, impregnates the germen or ovarium below (ſee STYLUS and GERMEN;) and after this operation of nature, the fruit or ſeed immediately take their growth, which, in ſome plants, is very quick and conſpicuous, particularly exemplified in the cucumber; as I have often obſerved, that from the time of impregnating the female flower with the Antheræ of the male bloſſom, which I always practiſe to the early crops, that the fruit, from the ſize of a large barley-corn, have obtained four, five, or ſix inches in length in a fortnight; the cucumber and melons being androgynous plants, i. e. produce male and female flowers apart on the ſame root, that the office of fecundating the fruit naturally, is ſuppoſed to be accompliſhed in the general ſummer crops in the full ground, by the winds or inſects, ſuch as bees, flies, &c. conveying the male duſt, and ſhedding it over the ſtigma or pointal of the female flower; but in the early crops in hot-beds, under frame and glaſſes, where we may ſuppoſe the winds and inſects have

have no acceſs, recourſe is had to art, to perform the office of impregnation, or, as the gardener's call it, ſetting the fruit, which is effected by carrying the ſtamina of the male, commonly, though improperly, called the falſe bloſſom, to the female, and touching the ſtigma therewith, ſo as to leave part of the duſt of the Antheræ, and in a day or two after the fruit will viſibly ſwell. See the *Culture of Cucumbers*.

The above operation of impregnating cucumbers with the Antheræ of the male bloſſom is ſo eſſential, that I adviſe every one to practiſe it with the utmoſt attention in the early crops, as from many years experience I can affirm it to be of the greateſt importance, for I always made ſure of my firſt fruit, and even every one that ſhewed and bloſſomed; whereas, when left entirely to nature, in the early crops, ſeldom one in ten or twenty ſtands; but when the ſeaſon arrives that the plants can be expoſed to the free air, that function is always ſufficiently effected, as above obſerved, by the winds, inſects, &c. or by ſome other unknown operation of nature. *Vide* CUCUMIS, IMPREGNATION OF FRUIT, SEXUS, &c.

The moſt natural ſtructure of the Antheræ, which obtain in the greater number of plants, is, in point of ſituation, placed on the top of the filament; in point of number, a ſingle Antheræ to each filament, though ſome plants have two, others three, four, and five Antheræ.

The connection of the Antheræ with the filament is either *Erectæ*, erect, or ſtrait, and faſtened by either end to the top of the filamant; *Incumbentes*, incumbent, or lie ſideways upon the filament; or *Verſatiles*, veering about like a vane.

The figure and reſemblance of the Antheræ is various, ſome are *Linearis*, linear, or ſlender, like a thread; *Subulata*, or awl-ſhaped; *Haſtata*, ſpear, or javelin-ſhaped; *Bicornes*, two-horned; *Bifida*, parted halfway; *Biloba*, divided into two; *Sagittata*, arrow-ſhaped; *Cordata*, heart-ſhaped; *Reneformis*, kidney-ſhaped; *Ovata*, egg-ſhaped, *Globoſa* or *Rotunda*, globular or round; *Trigona*, three cornered; *Tetragona*, four cornered; *Lunalata*, creſcent, or moon-ſhaped; *Acuta*, ſharp, terminated in an acute angle; *Acuminata*, tapering to a point; *Obtuſa*, obtuſe, or blunt; *Diſtincta*, diſtinct, or unconnected with each other; *Connivens*, approaching each other; *Incurva*, bowed, or crooked; *Villoſa*, hairy and woolly; *Hirſuta*, rough and hairy; *Membranacea*, membranaceous or hard, like parchment; *Pellucida*, ſhining or tranſparent.

ANTHERICUM, Spider-Wort.

The plants are herbaceous, moſtly perennial, and of the flowery kind, obtaining in ſtature, in different ſpecies, from three inches to three feet, adorned with hexapetalous liliaceous flowers, diſpoſed in ſpikes.

Claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX none. COROLLA, ſix obtuſe ſpreading petals. STAMINA, ſix filaments, and incumbent furrowed antheræ. PISTILLUM, a trigonous germen, ſimple ſtyle, and trigonous ſtigma. PERICARPIUM, a ſmooth three-furrowed capſule, of three cells, containing many ſeeds.

There are twelve ſpecies, thoſe that claim attention are,

[1]ANTHERICUM *Revolutum*.

*Revolute-flowered Anthericum.*] Anthericum with flat rough leaves, erect branching ſtalks, two feet high, each branch terminated by a looſe ſpike of white flowers, having the petals rolled back.

[2]ANTHERICUM *Ramoſum*.

*Ramoſe-ſtalked plane-flowered Anthericum*] Anthericum with flat leaves, erect very branching ſtalks, two feet high, each branch terminated by a looſe ſpike of white flowers, with ſtrait petals.

[3]ANTHERICUM *Liliago*.

*Liliago or Single-ſtalked Anthericum.*] Anthericum with plane flat leaves, an erect unbranched ſtalk, a foot and half high, ſupporting one looſe ſpike of white flowers.

[4]ANTHERICUM *Liliaſtrum*.

*Liliaſtrum, or St. Bruno's Lily.*] Anthericum with plane, flat, erect leaves, erect undivided ſtalk, fifteen or eighteen inches high, and large bell-ſhaped, lily-like, white, odoriferous flowers at top of the ſtalk, hanging on one ſide, which are very pretty, but rarely endure five or ſix days.

[5]ANTHERICUM *Fruteſcens*.

*Shrubby-ſtalked Anthericum, or Onion-leaved Aloe.*] Anthericum with ſeveral ſhrubby-branches from the root, each ſupporting a head of taper, onion-like, fleſhy leaves, and looſe ſpikes of yellow flowers.

[6]ANTHERICUM *Aloeoides*.

*Aloe-leaved Anthericum.*] Anthericum with broad, flat, awl-ſhaped, fleſhy leaves, riſing from the root, ſpreading on the ground, and looſe

looſe ſpikes of yellow flowers riſing among the leaves.

7 ANTHERICUM *Aſphodeloides.*

*Mock-Aſphodel Anthericum*] Anthericum with long, narrow, awl ſhaped, half-tapered, fleſhy leaves, gathered cloſe together, and looſe ſpikes of yellow flowers riſing among the leaves.

The four firſt ſpecies are hardy perennials, the roots are moſtly fleſhy tubers, eſpecially the three firſt; the leaves and ſtems riſe from the root annually in ſpring, flower in June and July, and ripen ſeed in autumn.

All theſe are proper furniture for the principal compartments of the pleaſure ground.

The *Anthericum Fruteſcens*, *Aloeoides*, and *Aſphodeloides*, are green-houſe plants, ſo muſt be retained always in pots; they are ſucculent, and retain their leaves, and flower at different ſeaſons, and often perfect ſeeds.

The flowers of all the ſorts are liliaceous, and compoſed each of ſix equal petals. See its *Characters.*

*Propagation.*

The *Anthericum Revolutum*, *Ramoſum*, and *Liliago*, are propagated by ſeed, in a bed or border of light earth, in September or October, and the plants will riſe plentifully in ſpring; which, in autumn, when the leaves decay, tranſplant into a freſh bed, nine inches diſtance, to remain a year; then remove them into the borders, &c.

The roots ſometimes afford off-ſets, which may be ſeparated for encreaſe in autumn.

The St. Bruno's Lily multiply freely by off-ſets of the roots, which may be divided in autumn, planting the ſmall ſlips in a nurſery bed for a year, and the larger ones at once where they are to remain.

The three green-houſe kinds may be raiſed from ſeed, but they encreaſe exceedingly by off-ſets or ſuckers, which may be taken off in ſummer, and planted in pots of light ſandy earth, and in winter muſt have the ſhelter of a green-houſe or garden-frame, and managed as other ſucculent plants.

ANTHOLYZA, ſometimes called Æthiopean Corn Flag.

The plants are herbaceous perennials, of the bulbous-rooted tribe, producing ſtalks from one to two feet high, ornamented with cluſters of large monopetalous flowers, of ſingular ſtructure and beauty.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX is a ſpathæ. COROLLA, one irregular ringent petal, tubular below, widening gradually to a large compreſſed ringent mouth, the upper lip very long and erect, with two ſhort wings at the baſe; the under lip ſhort and trifid. STAMINA, three long filaments, and pointed antheræ. PISTILLUM, a germen below the corolla, ſlender ſtyle, and trifid ſtigma. PERICARPIUM, a trigonous capſule of three cells, and many ſeeds.

The ſpecies are,

1 ANTHOLYZA *Ringens.*

*Ringent or Gaping ſcarlet Antholyza.*] Antholyza with narrow, rough, furrowed leaves, a foot long; round hairy flower-ſtalk, two feet high, ornamented upward with ſeveral red flowers, having compreſſed jaws and gaping lips.

2 ANTHOLYZA *Spicata.*

*Half-ſpiked White Antholyza.*] Antholyza with long, narrow, deeply-furrowed leaves; a flower-ſtem eighteen inches high, and white flowers, ranged all on one ſide, ſtanding erect.

3 ANTHOLYZA *Æthiopica.*

*Æthiopean Crimſon Antholyza.*] Antholyza with long, narrow, deep-green leaves; a round flower-ſtem a foot high, the top ornamented with large, incurved, crimſon flowers.

4 ANTHOLYZA *Cunonia.*

*Cunonia, or Large Spathæed Scarlet Antholyza.*] Antholyza with narrow, ſword-ſhaped, pointed leaves, nine inches long, riſing in autumn, and the flower-ſtem in ſpring, eighteen inches high, ornamented upward with large ſcarlet flowers, have a large ſpathæ, and want the under lip.

Theſe are exotics of Africa, and require the protection of a ſtove or good green-houſe in winter, ſo muſt be always retained in pots.

They have bulbous perennial roots, but the leaves and ſtems are annual, riſe in ſpring, and flower in May and June; the flowers are elegant, and univerſally monopetalous, long, hollow, divided into ſix irregular ſegments, one of which is conſiderably extended, the whole extremely ſingular and beautiful, and are ſucceeded by plenty of ripe ſeeds in autumn.

Their propagation is by off-ſets from the roots, which may be taken up and ſeparated when the leaves decay.

They may alſo be propagated with facility by ſeeds ſown in autumn, in pots of light earth, which place in the green-houſe in winter, and the plants will appear in ſpring, and in two years tranſplant them into ſeparate pots.

ANTHOSPERMUM, Amber-Tree.

This is a beautiful, evergreen, odoriferous ſhrub, of the green-houſe.

Claſs and order, *Polygamia Dioecia*, i. e. hermaphrodite, and male and female flowers upon one plant, and only males or females upon another.

There are two ſpecies.

[1]ANTHOSPERMUM *Æthiopicum.*

*Æthiopean Smooth Amber-Tree.*] Anthoſpermum with an erect very branching ſtem, and numerous, very ſmall, ſmooth leaves.

[2]ANTHOSPERMUM *Ciliare.*

*Ciliated Cape Anthoſpermum.*] Anthoſpermum with procumbent or trailing ſtalks, eight or ten inches long, and narrow ſpear-ſhaped leaves, having hairy borders.

The *Anthoſpermum Æthiopicum* is the ſort commonly known here; it is a low ſhrub, the ſtem erect, and divides into numerous ſlender branches, cloſely covered with very ſmall, ever-green, fragrant leaves, and flowers from the ſides of the branches, which being devoid of petals, have no beauty; ſo that the merit of the plant is its being a pretty ever-green, of delightful fragrance.

Both theſe ſpecies require the ſhield of a green-houſe in winter, ſo muſt be cultivated in pots.

The propagation of both ſorts is effected by cuttings and layers of their young branches; the cuttings may be planted in May, June, or July, either in pots, or in a bed or border, giving occaſional ſhade, and they will be fit to tranſplant into ſeparate pots in two or three months.

ANTHYLLIS, *Barba Jovis*, or Jupiter's Beard; alſo Silver Buſh.

This genus furniſhes ever-green ſhrubs and herbaceous plants; the former chiefly merit culture, which are exotics of the green houſe, adorned with compound leaves, and papilianaceous, or butterfly-ſhaped flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, monophyllous, ſwelling, five-parted, and permanent. COROLLA is papilionaceous, the ſtandard long, both ſides reflexed, the wings and keel ſhort. STAMINA, ten filaments, ſimple antheræ. PISTILLUM, an oblong germen, ſimple ſtyle and ſtigma. PERICARPIUM, a roundiſh pod, having one or two ſeeds.

The ſpecies are,

[1]ANTHYLLIS *Barba Jovis.*

*Common Barba Jovis, or Jupiter's Beard.*] Anthyllis with ſhrubby ſtem and branches, nine or ten feet high, ornamented with winged ſilvery leaves, compoſed of many lobes, and bright yellow flowers in bunches at the ends of the branches.

[2]ANTHYLLIS *Cytiſoides.*

*Baſtard Cytiſus, or Ternate-leaved Spaniſh Barba Jovis.*] Anthyllis with ſhrubby ſtem and branches, two feet high, leaves compoſed of three oval hoary lobes, and yellow flowers, by twos or threes from the ſides of the branches.

[3]ANTHYLLIS *Heterophyllis.*

*Dwarf Portugal Barba Jovis*] Anthyllis with low ſhrubby ſtem and branches, ſpreading near the ground, pinnated ſilvery leaves, terminated by an odd lobe, and ſmall variegated flowers at the ends of the branches.

[4]ANTHYLLIS *Hermaniæ.*

*Cretan Ternate-leaved Barba Jovis.*] Anthyllis with ſhrubby ſtem and branches, riſing five feet high, ternate leaves, and yellow flowers in cluſters from the ſides of the branches.

[5]ANTHYLLIS *Erinacea.*

*Erinacea, or Prickly Anthyllis.*] Anthyllis with ſhrubby and very prickly ſtem and branches, growing ſix or eight feet high, oval ſimple leaves, and purpliſh flowers.

Theſe are all exotic ever-greens of the green-houſe, ſo muſt be always kept in pots for the convenience of moving them in and out occaſionally.

They are natives of Portugal, Spain, Italy, and Greece.

The *Anthyllis Barba Jovis* is a moſt beautiful ever-green ſhrub, although it may be ſaid to be white, for the leaves appear of a ſilvery white colour, hence it is ſometimes called Silver Buſh.

The *Anthyllis Cytiſoides* is alſo a pretty hoary ſhrub.

The other three ſpecies are at preſent but rare in this country.

All the ſorts flower annually in June and July; the flowers are univerſally butterfly-ſhaped, having a ſtandard, two wings, and the keel, which are often ſucceeded by ripe ſeeds in autumn.

The propagation of all the ſpecies is by ſeeds, cuttings, and layers.

By ſeeds, ſow them in pots in ſpring, which plunge in a moderate hot-bed juſt to bring up the plants, and they muſt afterwards be planted in ſeparate pots.

By cuttings, plant them in May or June, in

in a ſhady border, and they will be well-rooted by autumn.

Layers of the young branches may be performed at any time.

The following are herbaceous ſpecies of this genus.

[1]ANTHYLLIS *Montana.*

*Mountain Herbaceous Anthyllis, or Purple Milk Vetch.*] Anthyllis with trailing ſtalks, winged hairy leaves, having an equal number of lobes, and purple flowers in globular heads at the ends of the branches.

[2]ANTHYLLIS *Vulnaria.*

*Vulnaria, or Scarlet Lady's Finger.*] Anthyllis with ſlender ſtalks, winged leaves, of two or three pair of lobes, terminated by an odd one, and double heads of ſcarlet flowers at the ends of the ſtalks.

They are hardy perennials, and proper furniture for the pleaſure ground, and may be raiſed from ſeed in autumn or ſpring, and by parting their roots.

ANTIRRHINUM, Snap-Dragon, or Calve's-Snout; alſo *Linnaria*, or Toad-Flax, or Frog's-Mouth.

The plants are herbaceous, and of the flowery kind, producing erect ſtalks from one to three feet high, terminated by long erect ſpikes of numerous monopetalous grinning flowers.

The Snap-Dragons are often ſeen growing upon walls and ruins.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX is monophyllous, and deeply five-parted. COROLLA is monopetalous and ringent, the tube oblong, ſwelling, and opening above with a mouth, having two lips, the upper one two-parted and reflexed on each ſide, the under one trifid and obtuſe, and a prominent nectarium at the baſe of the flower. STAMINA, two ſhort and two long filaments. PISTILLUM, a roundiſh germen, ſimple ſtyle, and ſtigma. PERICARPIUM, a roundiſh capſule, having many ſeeds.

The four following are of the Snap-Dragon *Antirrhinums*, diſtinguiſhed from the *Linnaria* by having the nectarium placed within the corolla, which, in the Toad-Flax, is extended at the baſe like a ſpur or horn.

[1]ANTIRRHINUM *Majus.*

*Great Perennial Snap-Dragon.*] Antirrhinum with erect ſtems, two or three feet high; ſpear-ſhaped leaves, having foot-ſtalks, and the ſtem terminated by a long ſpike of many large flowers.

*Varieties.*] Great Perennial Snap-Dragon with red flowers—with white flowers—white and red flowers——with white mouthed red flowers—with yellow flowers—yellow and red flowers——yellow and white flowers——with purple flowers—purple and white ſhaded flowers—and Variegated-leaved Great Snap-Dragon with flowers of different colours.

[2]ANTIRRHINUM *Latifolium.*

*Broad-leaved Greateſt Perennial Snap-Dragon.*] Antirrhinum with erect ſtems, a yard high; broad ſpear-ſhaped ſmooth leaves, on ſhort foot-ſtalks, and the ſtem terminated by a very long ſpike of many elegant large flowers.

*Varieties.*] The flowers of many different colours like the former.

[3]ANTIRRHINUM *Italicum.*

*Italian Perennial White Snap-Dragon.*] Antirrhinum with ſtems two feet high, very long, narrow, ſpear-ſhaped, hairy leaves, the ſtems adorned at top with a ſhort robuſt ſpike of large white flowers.

[4]ANTIRRHINUM *Siculum.*

*Sicilian Annual White Snap-Dragon.*] Antirrhinum with ſtems fifteen inches high, narrow ſpear-ſhaped alternate leaves, white flowers with purple bottoms, ariſing ſingly on long foot-ſtalks from the ſides of the branches.

The following are the *Linarias*, or Toad-Flax *Antirrhinums*, diſtinguiſhable from the Snap-Dragons by the flower being terminated behind by the nectarium, like a ſpur or horn, on which conſideration, Miller ranges it as a diſtinct genera; but Linnæus places them among the *Antirrhinums.*

[5]ANTIRRHINUM *Linaria, Vulgaris.*

*Linaria, or Common Toad-Flax* ] Antirrhinum with many erect ſtems, eighteen inches high, adorned below with numerous, very narrow, ſpear-ſhaped, grey leaves, in cluſters, and each ſtem terminated by a long ſpike of many cloſe-ſitting flowers.

*Varieties.*] Common large Toad-Flax with yellow flowers, and golden chaps.—Large White Toad-Flax——Small Yellow Toad-Flax.

[6]ANTIRRHINUM *Purpureum.*

*Great Purple Sweet-ſcented Linaria.*] Antirrhinum with many erect, branching, very flowery ſtems, a yard high, long, narrow, ſpear-ſhaped leaves, placed ſparſedly, all the ſtems terminated by long looſe ſpikes of many large, purple, ſweet-ſcented flowers.

[7]ANTIRRHINUM *Triſtis.*

*Dark-mouthed Gibraltar Toad-Flax.*] Antirrhinum

rhinum with many declinated ſucculent ſtalks, hardly a foot long, very ſhort, narrow, ſucculent leaves, oppoſite below, but irregular above, the ſtems terminated by cluſters of cloſe-ſitting yellow flowers, ſtriped with purple, dark purple chaps, and awl-ſhaped nectariums.

[8]ANTIRRHINUM *Arvenſis.*

*Field, or Wild Blue Toad-Flax.*] Antirrhinum with many erect, very branchy ſtems, two feet high, narrow leaves in whorls below, by pairs or ſingly above, and all the ſtems and branches terminated by looſe ſpikes of many ſmall blue flowers.

*Variety.*] Field Toad-Flax with yellow flowers.

[9]ANTIRRHINUM *Dalmatica.*

*Dalmatian Shrubby Yellow Toad-Flax.*] Antirrhinum with a ſtrong, erect, woody ſtem, a yard high, broad, ſpear-ſhaped, alternate, cloſe-ſitting leaves, and large deep yellow flowers, in looſe ſpikes, at the ends of the branches.

[10]ANTIRRHINUM *Triphylla.*

*Three-leaved Annual Toad-Flax.*] Antirrhinum with erect branchy ſtems, near two feet high, oval ſmooth leaves by threes, and ſhort ſpikes of flowers terminate the branches.

*Varieties are,*] Three-leaved Toad-Flax with yellow flowers——yellow with purple ſtandard and ſpur——with purple flowers.

All theſe plants are herbaceous, and all perennials, except the *Antirrhinum Siculum* and *Triphylla*, which are annuals, and are moſtly of hardy temperature, and will ſucceed in any of the common compartments of the pleaſure ground; though the *Antirrhinum Triſtis* and *Dalmatica* is ſomewhat impatient of ſevere froſt.

The roots are fibrous, the ſtems riſe ſeveral from each root, and the leaves are univerſally ſimple, and moſtly long and narrow.

The flowers are formed univerſally of one hollow, grinning petal, reſembling the ſnout and mouth of an animal, hence the names Snap-Dragon, Calve's-Snout, Frog's-Mouth, &c.

*Culture of the Snap-Dragon Kinds.*

The Snap-Dragon *Antirrhinums* are extremely pretty garden flowers, but more particularly thoſe of the *Antirrhinum Majus* and *Latifolium*, and are of remarkably eaſy culture, as is obvious by the plants riſing ſpontaneouſly from the ſelf-ſown or ſcattered ſeeds, even out of the crevices of walls, buildings, and ruins, ſo that they are alſo good furniture for artificial ruins, rock-work, &c. And in gardens, thoſe that grow in dry, ſandy, gravelly, rubbiſhy, or any dry hungry ſoil, are alſo of ſeveral years duration; though in rich land they grow ſtrongeſt, and the flowers will be more large and elegant; in which ſoil, however, they are apt to acquire a luxuriancy, or ſpongineſs, and rarely abide longer than one or two years; but this is no inconvenience, ſince they may be raiſed plentifully by ſeed and by ſlips and cuttings.

They flower from June to the end of ſummer, and ripen plenty of ſeed in autumn.

The ſeeds may be ſown in March, April, and May; thoſe ſown in March will flower the ſame year in autumn, and the others the year following. Sow them in a bed of light ſoil, and when the plants are three inches high, tranſplant them; thoſe you intend ſhall blow the ſame year, may be ſown in patches where they are to flower, as directed for hardy annuals.

By ſlips and cuttings is the method to continue the variegated-leaved ſort; any of the others will alſo grow freely by cuttings in a ſhady border in ſummer.

The variegated kind is rather impatient of ſevere froſt, and a few plants ſhould be potted to be houſed in winter.

*Culture of the Toad-Flax Kinds.*

Of the Toad-Flax *Antirrhinums*, the Common *Linaria*, *Antirrhinum Purpureum*, *Arvenſis*, and *Triphylla*, are proper furniture for the common compartments of large pleaſure grounds. The Purple *Linaria* particularly merit a place in every garden. All theſe ſorts flower in June, and continue in ſucceſſion till the end of ſummer, and are ſucceeded by abundance of ſeed in autumn.

The Common Toad-Flax grows wild by the way ſides, that of banks, hedges, and paſtures, as alſo the *Antirrhinum Arvenſis*; but by culture in gardens they grow ſtrong, and produce larger flowers.

All the ſorts may be raiſed plentifully from ſeed, the ſame as the Snap-Dragons; and the perennial ſorts alſo by parting the roots.

The Dalmatian *Linaria* and *Antirrhinum Triſtis* are ſomewhat tender, and ſome plants ſhould be potted to be houſed in winter, and ſome may be planted in warm dry borders; they flower in June and July, but rarely afford ſeeds here.

They are eaſily encreaſed by ſlips and cuttings of their branches in ſummer, or by parting their roots in autumn.

APETALUS *Flos*, i. e. Apetalous Flowers. By botaniſts, a flower is ſaid to be Apetalous that wants the corolla, petals, or flower-leaves.

Of this ſort are many of the amentaceous flowers, moſſes, ferns, and graſſes.

APIUM, Parſley, likewiſe Celery and Smallage.

By the laws of botany this genus comprehends all the ſorts of Parſley and Celery, all of which are uſeful herbaceous biennials, of the kitchen garden.

Claſs and order, *Pentandria Digynia.*

*Characters.*] The flowers grow in compound umbels, each umbel compoſed of many florets, each floret of five petals, five ſtamina, two ſtyles, and ſucceed by two ſeeds.

The ſpecies are,

[1]APIUM *Petroſelinum.*

*Common Parſley*, of which are two varieties, *viz.* Common Parſley with plane leaves.—— Common Parſley with curled leaves.

[2]APIUM *Latifolium.*

*Broad-leaved large-rooted Parſley.*] Apium with a large carrot-ſhaped, ſweet, eatable root, radical leaves divided into three ſerrated large lobes, and have very long foot-ſtalks.

[3]APIUM *Dulce.*

*Sweet Apium, or Common Upright Celery.*] Apium with upright leaves, ſupported on long erect foot-ſtalks, the folioles of the leaves compoſed of five ſerrated lobes.

*Of this are two varieties, viz.* Common Upright Celery with the ſtalks of the leaves fiſtular or hollow —Common Upright Celery with the ſtalks of the leaves ſolid ; — known by the names of Hollow Celery, and Solid Celery.

[4]APIUM *Rapaceum.*

*Turnep-rooted Spreading Celery.*] Apium with a large round turnep-ſhaped root, ſpreading leaves on ſhort foot-ſtalks, and the folioles of the leaves compoſed of five ſerrated lobes.

[5]APIUM *Graveolens.*

*Rank-taſted Apium or Smallage.*] Apium with the cauline leaves, having wedge-ſhaped lobes.

All theſe plants are herbaceous, and of hardy growth, and all of the biennial tribe, i. e. of only two years duration ; the firſt year they produce only leaves, and attain perfection for kitchen uſe ; the ſecond ſpring they ſhoot up ſtalks, flower, and perfect ſeed, and in autumn periſh, root and branch ; ſo that they continue uſeful only one year, and a freſh ſupply muſt be raiſed annually from ſeed.

Some of the ſpecies, if ſown very early, run to ſeed the ſame year, particularly the Celery.

*Firſt, of the Common Parſley.*

The two varieties of the *Apium Petroſelinum*, i. e. the Plane and Curled Parſley, are moſt uſeful culinary and medical herbs, their leaves being in great requeſt for various kitchen uſes, and their roots for medicine.

With reſpect to the properties of theſe two varieties of Apium ; for uſe, their virtues are the ſame both for food and medicine ; the plane-leaved ſort is moſt commonly cultivated, but many prefer the curled kind, for theſe reaſons, becauſe its leaves are eaſily diſtinguiſhed from thoſe of the *Æthuſa*, or Fool's-Parſley, a ſort of hemlock, and a poiſonous garden weed, which, while young, has great reſemblance to the Common plane-leaved Parſley, ſee ÆTHUSA. Likewiſe, the Curled Parſley having larger and thicker leaves, and being curiouſly fimbricated and curled, appearing full and double, make a pretty appearance in its growth, and is greatly eſteemed by cooks as a fine garniſh to diſhes. It is to be however remarked that this ſort, as being only a variety, it will degenerate to the common plane ſort, unleſs particular care is taken to ſave the ſeeds always from the perfect curled plants.

Both the varieties of Common Parſley are propagated by ſeed ſown where the plants are to remain, annually in ſpring, for the plants are biennials, riſing from ſeed in March, April, or May; continue uſeful until that time twelvemonth, then ſhoot up, ſtalk, perfect ſeed, and periſh.

The ſeaſon for ſowing both varieties, is any time from the beginning of February until the beginning of May, though they will grow almoſt any time of the year ; however, to have the plants come in for uſe by the time the old Parſley begins to run, it is proper to ſow in February or March, and the plants will be fit to cut in May, or beginning of June.

It is moſt eligible to ſow this ſeed in drills, as it will be more convenient to clean and gather the herbs for uſe. Where only a ſufficiency is required for the ſupply of a family, it may be ſown in a ſingle drill along the edges of the borders, or quarters of the kitchen garden, and the plants will ſerve a double purpoſe, for they will form an edging, and give an air of regularity and neatneſs to the place, at the ſame time yield their produce plentifully ; but for the ſupply of markets, the London gardeners ſow it alſo in large plats, either in broad caſt, and rake it in, or in ſhallow drills, eight or nine inches diſtance,

tance, and trim the earth evenly over it, near half an inch deep, and lightly rake the ſurface ſmooth.

This ſeed is ſo extremely ſlow in its vegetative motion, that its germination, or at leaſt, the appearance of the plants, is not to be expected in leſs than five or ſix weeks.

All the culture the plants require is to be kept clean from weeds, and when they at any time grow faſter than is wanted for uſe, as is often the caſe in private gardens, they, when grown rank and ſpreading, ſhould be cut down cloſe; this ſhould be particularly practiſed in autumn, i. e. about Michaelmas, time enough for the plants to recover before winter, and numerous young leaves will riſe from the roots, and form a thick compact edging.

To ſave Parſley ſeed, permit ſome rows of the one year old plants to ſtand, and they will ſhoot up their ſtalks in May and June, and ripen ſeed abundantly in July and Auguſt.

*Of the Second Species, Broad-leaved large-rooted Parſley.*

The *Apium Latifolium*, or Broad-leaved Parſley, is eſteemed for its large roots, which are boiled and eaten as ſauce to fleſh meat.

Theſe roots are white and carrot-ſhaped, being long, taper, and of downright growth, and often obtain the ſize of a middling carrot; they boil exceeding tender and palatable, are very wholeſome, and may be uſed in ſoup or broth, or to eat like carrots and parſneps; the uſe of them is greatly recommended to perſons that are ſubject to the gravel, and are uſed in decays of many kinds.

They are raiſed in great perfection by the London gardeners, who ſupply the markets with them in bunches.

Their ſeaſon for uſe is from July until Chriſtmas, or even till March.

The propagation of this ſpecies of Apium is by ſeed ſown where the plants are to remain, annually in February, March, or April. Chuſe a ſpot of light rich earth, in an open expoſure; ſow the ſeed broad-caſt, and rake it in: the plants will appear in April, and in May they will require to be thinned, and cleared from weeds, which may be performed either by hand or hoe, but the latter is moſt eligible, as it will ſtir and looſen the ſurface, which will be beneficial to the plants, cutting them out to about ſix inches diſtance.

In the latter end of July the roots will have attained a due ſize for uſe, when ſome may be drawn occaſionally, but they do not acquire their full growth until Michaelmas.

This ſort is ſometimes called Hamburgh Parſley, becauſe the plants are greatly cultivated in the gardens near that city.

*Of the Third Species, Common Celery.*

The *Apium Dulce*, or Common Celery, in both its varieties, is in univerſal eſteem as a culinary and ſallad herb, and the ſtalks of its leaves are the only parts uſed, which are excellent in ſoups, and for ſtewing, and as an autumnal and winter ſallad herb, it ſurpaſſes many others. It may be obtained for uſe nine or ten months in the year, that is, from July until the middle or end of May; but the ſeaſon of its greateſt perfection, is from about the middle or latter end of Auguſt till Chriſtmas, or even till March, if the winter do not prove ſevere.

Both the varieties are of upright growth, and obtain two feet and half in height, which, by the culture of planting them out in trenches, together with ſeveral repetitions of earthing up their ſtalks as they advance in ſtature, they become very white, tender, and palatable, which otherwiſe would be tough and rank-taſted.

The Hollow Celery is the original variety, having been long known before the ſolid kind, the ſtalks of the latter having no hollow or vacancy in the middle; the former have, and is the principal difference, for they poſſeſs equal properties for general uſe, though the ſolid kind is often preferred for ſoups and ſtewing; but we however do not recommend it for a general winter crop, becauſe it will not endure froſt ſo well as the common Hollow Celery, nor for market ſervice, it being very brittle, will eaſily break in waſhing and bunching up, as practiſed by the London gardeners, who bind ſix, eight, ten, or twelve heads, placed ſingly, but cloſe together, in a flat ſpreaded bunch.

Their propagation and culture is as follow.

They are propagated by ſeed ſown in the ſpring, and when the plants have attained ſix or eight inches in height, they are to be tranſplanted into trenches, in order to be earthed up on each ſide as they advance in growth, to blanch or whiten their ſtalks, to render them criſp and tender. See *Tranſplanting* and *Earthing them up*.

A freſh ſupply of plants muſt be raiſed annually, for the plants continue uſeful but one year.

The proper periods of time for ſowing it,

are, that, if a regular ſucceſſion of plants is required, eight or nine months in the year, it is neceſſary to perform three different ſowings from the beginning of March until the middle of May.

As for example, if it is intended to have Celery for uſe as early as poſſible in ſummer, i. e. in July, ſow ſome ſeed the firſt week in March, on a warm border; or, to bring the plants more forward, in a ſlender hotbed; or if you are anxious to have very early Celery, ſome ſeed may be ſown in the middle of February; but as theſe very early ſown plants are apt to pipe, or run for ſeed the ſame year, before they attain half their perfection, a few ſhould only be raiſed.

But for the general or principal crops, to come in for autumn and winter ſervice, that is, in Auguſt or September, and continue in perfection till Chriſtmas or ſpring, the ſeed ſhould be ſown towards the latter end of March, or in the firſt or ſecond week in April, in a bed of natural earth, in an open expoſure, and if a little more is ſown in the latter end of the laſt named month, or in the firſt or ſecond week in May, it will furniſh a latter crop to come in for uſe the beginning of November, and continue good until the latter end of March; and by planting ſome in ſhallow trenches about Michaelmas, and in October and November, they will be fit for uſe in March and April, and continue without running till the middle or latter end of May.

We obſerved above, that the early crop may either be ſown upon a warm border of natural earth, or upon a hot-bed of ſlender ſtructure; by the latter practice, the plants may be ſo forwarded as to be fit to tranſplant into trenches ſooner by three weeks or a month, than thoſe raiſed in the natural ground; a ſmall bed, about eighteen or twenty inches depth of dung, will be ſufficient, which may be ſheltered either with a ſmall frame, or occaſionally with mats ſupported on arches; lay thereon five or ſix inches of rich light earth, ſow the ſeed on the ſurface, and cover it near a quarter of an inch deep; when the plants appear, admit the full air freely in mild days, but ſhelter them with a glaſs or mats on nights, until they acquire ſome ſtrength, and give frequent light watering; and when the plants, of either ſowing, are two inches high, ſome of the ſtouteſt ſhould be pricked out into a bed of rich earth, in a ſheltered ſituation, three inches apart; or to bring them ſtill more forward, ſome might be pricked upon a ſlender hotbed, occaſionally ſheltered with mats, giving water and occaſional ſhade till they have ſtruck root; and if rain do not fall, refreſh them frequently with water, as you ſhall ſee neceſſary.

Thoſe that were firſt pricked out, will, in May or the beginning of June, be five or ſix inches high, when ſome of the ſtrongeſt ſhould be tranſplanted into trenches, in order to their being blanched. See *Tranſplanting into Trenches*, next page, &c.

With regard to ſowing the main and latter crops, obſerve the following directions.

At the times above noticed, make choice of a ſpot of rich light earth, in an open ſituation, and let it be then neatly dug, and divided into one or more beds; but one ſmall bed is ſufficient for private uſe, which ſhould be three feet and half wide, making the ſurface level and ſmooth; this done, the ſeed may either be ſown on the ſurface, and raked in lightly, or otherwiſe firſt rake the ſurface fine, then ſow the ſeed, and ſift earth over it near a quarter of an inch thick; or if the ſurface being firſt raked ſmooth as above, then, with the back of a rake, ſhove the earth from off the ſurface a quarter of an inch deep into the alley; ſow the ſeed, and then with the rake turned the right way draw the earth on the bed again, with a kind of jerk, that it may ſpread and cover the ſeed equally in every part.

When the plants of either ſowing are come up, they ſhould, in dry weather, be frequently watered; do not omit this, particularly whilſt the plants are young.

When the plants of each ſowing are about three or four inches high, it is adviſeable to thin the ſeed-bed by pricking out a quantity of the ſtrongeſt into an open rich ſpot, properly dug and divided into beds three feet and half wide, taking opportunity, if poſſible, of moiſt weather, and prick the plants therein, in rows ſix inches aſunder, and three or four inches diſtant in each row, giving water, which, if dry weather ſucceeds, ſhould be occaſionally repeated, till they ſtrike freſh root, and in which bed they are to remain five or ſix weeks to acquire due ſtrength, previous to their being tranſplanted into trenches, in order for blanching.

The ſame ſeed-bed will afford three, four, or more different drawings to prick out as above, which, by obſerving to thin out the largeſt

largeſt regularly each time, before they draw each other weak by cloſe ſtanding, and prick them in beds till the ground intended for the trenches is at liberty, they will be advancing in their growth, and will be conſiderably better prepared, than ſuch that have remained all the time in the ſeed-bed.

*Tranſplanting them into the Trenches.*

The ſeaſon for tranſplanting theſe plants into the trenches for blanching, is occaſionally from the middle of May until the latter end of October, or even middle of November, according to the forwardneſs of the plants, time they are required for uſe, and the time it is intended they ſhall continue.

Obſerve, that when the plants are from about ſix to ten or twelve inches high, they are of a proper ſize for tranſplanting into the trenches.

It is neceſſary always to make, at leaſt, three different plantations, allowing the diſtance of three weeks between each time of planting; but when the plants are required for uſe as early in ſummer as poſſible, and to be continued as late in ſpring as the middle or latter end of May, it is eligible to plant five or ſix different crops, allowing the diſtance of time abovementioned between the planting each ſeparate crop; and obſerve that the crops intended principally for ſpring uſe, i. e. March, April, and May, ſhould not be planted in the trenches until October and beginning of November.

The manner of making the trenches, and tranſplanting the plants therein, is as follow.

Make choice of a rich ſpot of ground, in an open quarter, and if there be any weeds, hoe the ground, and rake them off; then, with a line and ſpade, mark and chop out the trenches croſs-ways the piece of ground, each trench twelve inches or one ſpade wide, and allow a ſpace of three feet between trench and trench, that there may be ſufficient ſcope to have a due portion of earth to land up the plants a proper height; the trenches being thus marked, then proceed to dig them out to form the cavity for the reception of the plants; obſerve to dig out each trench a moderate ſpade deep, without taking out any ſhovelling, laying the ſpits of earth alternately to the right and left in the ſpaces between, levelling it neatly, and beating up the edges firm and ſtrait, and then let the bottom be properly dug and levelled; or if the ground is poor, you may firſt ſpread therein two or three inches depth of rotten dung, and dig it in four or five inches deep.

The trenches being ready, get the plants and trim them by cutting off the ends of their roots, and the tops of the ſtraggling leaves; then plant one row exactly along the middle of each trench, placing the plants four or five inches diſtance; and directly give a hearty watering out of a pot with the roſe on, which, if ſhowers do not fall, ſhould be repeated every other evening at leaſt, till the plants have taken freſh root.

Do not plant out many of the very early plants, i. e. thoſe ſown in February, or early in March, becauſe they are apt to pipe almoſt as ſoon as they are blanched.

When it happens that the plants intended for the late crops have ſtood ſo long in the ſeed or pricking-out bed, as to become rank, and grown ſo cloſe as to draw each other up weak; in order to retard their running up tall, and to obtain them of ſhort and robuſt growth againſt October and November, to plant in ſhallow trenches, it is adviſeable, in Auguſt or September, either to cut them down low to ſhoot out again, or tranſplant them in rows nine inches diſtance.

*Earthing, or Landing up the Plants.*

As we before noticed, theſe plants, in order to whiten or blanch the ſtalks, and render them criſp, tender, and of a grateful flavour, ſhould, according as they riſe in height, be earthed or landed up on each ſide, uſing for that purpoſe the earth that was dug out of the trenches, and when that is expended, that in the ſpaces between them muſt be dug, broken, and uſed repeatedly as the plants advance in growth.

The proper period to begin this work of earthing, is when the plants are about ten or twelve inches high, and which ſhould be repeated every fortnight or three weeks, as you ſhall ſee neceſſary, during their principal growth.

In performing this work, regard muſt be had to break the earth moderately fine, and trim it up to the plants with attention, not to break the ſtalks of the leaves, nor force the mould into their hearts. At the firſt time of earthing, you may land them three, four, or five inches, according to the ſize and height of the plants, obſerving the ſame rule at each time of earthing them, till they are by degrees landed at leaſt twelve, but if fifteen or twenty inches, the better; which, if the ſoil is rich, and ſomewhat moiſt, thoſe of the main crop that are planted out in the end of June, or in July, ſometimes make ſuch progreſs, that if properly followed up with earth, they

they will, by October, be blanched eighteen inches, or near two feet in length.

The above work of earthing is to be continued to the latter crops, occaſionally, until Chriſtmas, or as long as the plants continue to grow in height during the winter; at which ſeaſon, i. e. November and December, it is proper to land them up pretty near their tops, in caſe of hard froſt ſetting in, which often deſtroys ſuch part of the plants as are out of the ground, which, if of conſiderable length, would occaſion the decay of moſt of the other parts within the earth.

In performing the different landings up, let it always, if poſſible, be done when the plants are dry, otherwiſe they are apt to become ſpotted and cankery.

*Of taking up the Plants for Uſe.*

Some of the firſt landed up plants, if they were planted in trenches in May or beginning of June, will be fit to take up in July, for when theſe early plants are blanched five or ſix inches in length, you may begin to take them up; for if they were ſown pretty early, they rarely continue long before they begin to pipe, and ſoon become uſeleſs.

But the plants of the main crop will not be blanched any conſiderable length till the latter end of Auguſt, or beginning of September, but will not acquire their full perfection until October, as we before obſerved. However, where there is a demand for the plants, you may begin to take ſome up when they are whitened ſix or ſeven inches, as, if properly followed with earthing, they will be encreaſing every day in length in the blanched part.

In winter, at the approach of very ſevere froſt, it would be of particular advantage to cover ſome of the rows of the main crop with dry long litter, to ſave the plants, and prevent the ground being frozen hard, that the plants may readily be dug up when wanted.

Likewiſe, at the approach of hard froſt, a quantity of the plants may be taken up for the uſe of a family, and laid in ſome dry earth in a ſhed, or other ſheltered place.

*Another Method of Planting Celery in Trenches for Blanching.*

There is a method of planting out the Upright Celery in trenches, but little known or practiſed in theſe parts; the manner of it is as follows:

Having fixed upon an open piece of ground, then with a line and ſpade cut or mark out a bed, or rather trench, ſix feet wide, croſsways the ground; this done, begin at one end, and proceed to dig out a cavity the above width and length, one ſpade deep, laying the ſpits of earth to the right and left in a ridge along each ſide of the ſaid cavity or trench, beating it up in front that it may not ſlip down, and when the trench is thus dug, looſen and level the bottom, and if dung is needful, let ſome be added, and dig it into the bottom four or five inches deep.

When more than one of ſuch trenches are to be made, allow a clear ſpace of ſix feet between trench and trench, to contain the earth dug out, and to have a ſufficiency to land up the plants.

Theſe trenches being prepared as above, then, having the plants and trimming them as before directed, proceed to plant them; but obſerving they are here to be planted in rows croſs-ways the trench, the rows to be a foot aſunder, and the plants to be ſet ſix inches diſtant in each row, and giving water as adviſed in the other method.

When the plants are of due height for earthing up, the earth that was thrown out of the trenches is to be firſt uſed, then that of the ſpaces; break it fine, and with the ſpade trim it in carefully between the rows of plants, in equal portions from each ſide of the trench, landing them up a due height, which is to be occaſionally repeated, obſerving the ſame rules as adviſed in earthing the plants.

In landing up the plants that are planted in the above method, it will be of advantage, when they have attained a large growth, to be furniſhed with a couple of thin boards, ſix feet long; theſe are to be uſed at the time of earthing, to ſlip into the ſpaces between the rows of plants, to keep the ſtalks and leaves up cloſe juſt till the earth is put in, placing them cloſe to the plants; then trim in the earth between the boards, and when one ſpace is thus earthed, draw out the boards and place them in the next, and in that manner proceed in earthing the ſeveral rows in every ſuch trench.

*Culture of the Fourth Species, Turnep-rooted Celery.*

The *Apium Rapaceum*, or Turnep-rooted Celery, is eſteemed principally for its root, which acquires a globular turnep-like form, and by culture becomes very white and tender, and is uſed for the ſame purpoſes as the Common Celery.

The leaves of this ſort ſpread out ſomewhat horizontally, and rarely exceed ten or twelve inches in length, which, when blanched,

blanched, may be uſed like the Upright Celery.

It is propagated by ſeeds, in an open rich ſpot, in March or April, ſowing it as directed for the common ſort, and when the plants are an inch or two high, thin them to three inches; and when they are four or five inches in height, tranſplant them into ſhallow trenches; previous to which, dig the ground all over, one ſpade deep, then with an hoe draw drills three inches deep, and eighteen aſunder, and ſet the plants therein, ſix inches diſtance, and give water.

When the plants are advanced nine or ten inches in growth, obſerve the progreſs of the roots, and when they have acquired a tolerable ſize, draw earth up to each ſide of the row of plants, three or four inches high, which one earthing is ſufficient to improve, the roots, which will be fit to take up for uſe in three or four weeks after.

*Of ſaving Seed of this Species.*

When it is intended to ſave Celery ſeed, leave a few of the fineſt plants in the places where they were planted out for blanching; they will ſhoot up their flower-ſtems in May and June, flower in July, and ripen their ſeeds in Auguſt, when the ſtalks ſhould be cut and ſet in the ſun a week to harden, then beat out the ſeed, and put it up in bags.

*Fifth Species, the Smallage.*

The *Apium Graveolens*, or Smallage, is a common weed, bearing great reſemblance to Celery, inaſmuch that the latter is by ſome ſuppoſed to be a variety of the former, raiſed to its preſent ſtate of perfection by long culture; but I greatly doubt this, ſince both ſorts retain their difference from ſeed.

This ſort is uſed in medicine, but rarely for culinary purpoſes, except ſometimes by poor country people to put in broth, or pottage, in default of other herbs.

It grows wild in moiſt places, and is ſeldom cultivated in gardens; but if wanted, it may be raiſed plentifully from ſeed in the ſpring.

APOCYNUM, Dog's-Bane.

This genus comprehends hardy herbaceous perennials, and tender ſhrubby exotics, all of the flowery tribe, obtaining from two to five or ſix feet ſtature, adorned with ſimple leaves, and monopetalous bell-ſhaped flowers in cluſters.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX is monophyllous, five-parted at the edge, and permanent. COROLLA is monopetalous, bell-ſhaped, and five-parted at the brim, and five oval nectariums at bottom. STAMINA, five filaments, and biſid antheræ. PISTILLUM, two germina, two ſmall ſtyles, and globular ſtigma. PERICARPIUM, two capſules, containing many ſeeds.

The ſpecies are,

[1]APOCYNUM *Androſæmi-folium.*

*Tutſan-leaved Canada Apocynum.*] Apocynum with upright herbaceous ſtalks, a yard high; large oval, ſmooth, ſtiff leaves, growing oppoſite by pairs, and the ſtalks crowned by cymoſe umbels of white flowers, having purpliſh nectariums.

[2]APOCYNUM *Cannabinum.*

*Dwarf Canada Dog's-Bane.*] Apocynum with upright herbaceous, reddiſh ſtalks, two feet high, oblong ſmooth leaves, ſet oppoſite by pairs, and the upper parts of the ſtalks terminated by greeniſh-white flowers in panicles.

[3]APOCYNUM *Venetum.*

*Venetian Willow-leaved Apocynum.*] Apocynum with erect herbaceous ſtalks, two feet high, oval ſpear-ſhaped ſmooth leaves, placed oppoſite by pairs, and the top of the ſtalks adorned with large flowers, collected into bunches.

*Varieties of this.*] Venetian Apocynum with purple flowers—with white flowers.

[4]APOCYNUM *Fruteſcens.*

*Shrubby Upright Ceylon Apocynum.*] Apocynum with a ſhrubby, erect, branchy ſtem, obtaining five feet in height, the branches adorned with oval ſpear-ſhaped, ſmooth, ſhining leaves, ſet oppoſite by pairs; and flowers collected into ſmall bunches, having an acute corolla, and hairy jaws.

*Varieties.*] Shrubby Apocynum with purple flowers——with yellow flowers.

[5]APOCYNUM *Reticulatum.*

*Climbing Veined-leaved Indian Dog's-Bane.*] Apocynum with a twining perennial ſtalk, climbing twenty or thirty feet high, oval, very much veined leaves, by pairs oppoſite; and ſmall bunches of flowers from the ſides of the branches.

*Varieties.*] With purple flowers—greeniſh flowers—with white flowers.

For other ſpecies of Dog's-Bane, ſee ASCLEPIAS, PERIPLOCA, and CYNANCHUM.

The three firſt ſpecies are hardy herbaceous perennials; the roots are fibrous, and very creeping; the ſtalks riſe annually from the root in ſpring, and periſh in autumn; the leaves are ſimple, and pretty large, which,

as

as well as the ſtalks, abound with a milky juice: the flowers are formed each of a ſingle hollow, bell-ſhaped petal; thoſe of the *Apocynum Venetum* are conſiderably the largeſt and moſt beautiful: they all flower in July and Auguſt, but rarely perfect ſeeds in Britain.

Theſe three ſorts and their varieties are proper furniture for the common compartments of the pleaſure ground.

The propagation of theſe three ſpecies is eaſily effected by their creeping roots, in autumn or ſpring, either by dividing the main root, or by joints thereof.

The *Apocynum Fruteſcens*, and Climbing Dog's-Bane, are tender exotics of the ſtove; the firſt has moſt claim to attention.

They may be propagated by ſeeds procured from abroad, and by cuttings and layers, either of which muſt be aſſiſted by a hot-bed, and the plants are to be potted and always retained in the ſtove.

AQUATICÆ *Planta*, Aquatic Plants, i. e. ſuch that grow in or near waters, either rivers, ponds, watery ditches, or other very marſhy places.

AQUILEGIA, Columbine.

The plants are hardy, herbaceous, flowery perennials, that obtain from one to three feet ſtature, adorned at top with many pentapetalous nectarious flowers.

Claſs and order, *Polyandria Pentagynia*.

*Characters.*] CALIX none. COROLLA, five oval, ſpear-ſhaped, ſpreading petals, and alternately with theſe are ranged five hollow and horned nectariums, their lower part lengthened to a long incurved tube. STAMINA, numerous filaments, and erect antheræ. PISTILLUM, five oval germina, five ſubulate ſtyles, and ſimple ſtigmas. PERICARPIUM, five erect cylindrical capſules, containing numerous oval ſhining ſeeds.

There are but three ſpecies, which are,

[1]AQUILEGIA *Hortenſis*.

*Garden, or Common Columbine.*] Aquilegia with upright ſtems, a yard high, dividing into many erect branches, leaves compoſed of many lobes, growing by threes, and all the branches terminated by the flowers, which have incurved nectaria.

Varieties of this are numerous, and ſingularly curious, which are,

Common Columbine with flowers compoſed of five petals, ranged alternately with five nectaria, as expreſſed in the characters.

Common Columbine with flowers compoſed of double petals, and nectaria ranged alternately.

Common Columbine with flowers, having no viſible nectaria, and compoſed principally of oval petals, of which there are ſingle and very double flowers; commonly called Roſe Columbines.

Common Columbine, having no viſible nectaria, and compoſed principally of ſharp-pointed petals, expanding like a ſtar, of which there are ſingle and perfectly double flowers, commonly called Starry Columbine.

Common Columbine with flowers, having no petals, being compoſed entirely of nectaria, of which there are ſingle, double, and trebly double flowers, having numerous nectaria, placed one within another, in a curious manner.

Common Columbine with inverted flowers.

Of each of the above varieties, there are blue flowers—white flowers—red flowers—purple flowers—fleſh-coloured flowers—aſh-coloured flowers—cheſnut-coloured flowers. ——Of variegated kinds there are, blue and purple flowers—blue and white flowers—with red and white flowers—blue and white flowers—with finely ſtriped flowers—with flowers having one part plain or ſelf-coloured, the other curiouſly ſtriped and ſpotted with different colours.

[2]AQUILEGIA *Vulgaris*.

*Wild Mountain Blue Columbine.*] Aquilegia with upright ſlender ſtems, two feet high, dividing into many ſlender erect branches, many-parted leaves, and large ſingle blue flowers terminate the branches, and with erect nectaria, and ſhort ſpear-ſhaped petals.

This grows wild in many places in woods and hilly grounds.

[3]AQUILEGIA *Canadenſis*.

*Canada Dwarf Early Columbine.*] Aquilegia with upright ſtalks, a foot high, dividing into ſlender erect branches, each terminated by a ſingle flower of a red colour, with a yellow middle, having erect nectaria, and ſtamina longer than the corolla.

All theſe ſpecies and reſpective varieties are hardy herbaceous perennials; the roots are fibrous, and the leaves and flower-ſtems riſe annually from the root in ſpring; the leaves are branching, and compoſed of many lobes, growing generally by threes; the ſtems divide into many branches, each terminated by the flowers, which are large, numerous, and very ſhowey, appearing in April, May, and June, and ripen ſeeds plentifully in Auguſt and September.

The *Aquilegia Hortenſis*, or Garden Columbine,

bine, in all its varieties, are choice furniture for pleaſure grounds of any extent, their flowers being large and numerous, and aſſuming many curious ſtructures, forms, ſizes, colours, and variegations, as to be extremely conſpicuous and ornamental in a garden, and thoſe of all the double variegated and ſtriped kinds particularly have ſingular elegance; and in ſhort, all the varieties are capable of forming a moſt agreeable diverſity, and they proſper freely in any common ſoil and expoſure, but make the fineſt appearance in an open ſituation.

It is remarkable that all the different varieties of this ſpecies, in regard to ſtructure, form, ſize, colour, and variegations of the flowers, are often obtained from the ſeed of the ſame plant.

All the varieties of this ſpecies flower in the end of May, and in June.

The *Aquilegia Vulgaris* have no ſtriking beauty, but the flowers being large, will form a variety in the common borders in May and June.

The Canada Columbine merits culture principally for its early bloom, which generally appear in April.

*Propagation, Culture, &c.*

Firſt of the *Aquilegia Hortenſis*. All the varieties of this ſort may be raiſed plentifully from ſeed, and by dividing their roots.

The ſeed may be ſown either in autumn or ſpring, in a bed or border of common light earth; dig the ground neatly one ſpade deep, ſow the ſeed moderately thick on the ſurface, and rake it in, and the plants will appear in April or May, giving occaſional water and weeding until June, July, or Auguſt, according to their ſize; then prick them out upon another bed in rows nine inches diſtance, and give occaſional watering during the hot weather. Next ſummer the plants will flower, but not ſtrong; when the beſt kinds ſhould be marked, in order to be removed in autumn into the moſt conſpicuous compartments, where they will flower ſtrong, and in their utmoſt perfection the year following, and continue ſeveral years.

In order to keep up a ſucceſſion of fine flowers, a ſupply of plants ſhould be raiſed from ſeed every two or three years, becauſe the old plants diſcover a degeneracy, that often, from the fulleſt doubles, and elegant variegations, become ſingle, and of plain colours.

By parting the roots, any variety may be encreaſed; but this ſhould be performed always upon the young plants of two or three years old, before they degenerate, which may be done in autumn or ſpring.

In ſaving ſeeds of this ſpecies, gather it always from the plants that exhibit the fineſt flowers.

The other two ſpecies, Mountain and Canada Columbines, are to be propagated in the ſame manner as the garden kinds.

All the culture neceſſary for the ſeveral kinds, is to keep them clean from weeds in common with other plants, and to cut down their decayed ſtems in autumn.

ARALIA, Berry-bearing Angelica, and Angelica-Tree.

This genus comprehends two herbaceous perennials, and one woody plant, of the tree kind.

Claſs and order, *Pentandria Pentagynia*.

*Characters.*] CALIX, globular umbel of flowers, having a ſmall involucrum, and very ſmall cup to the florets, reſting on the germen. COROLLA, the florets of the umbel have five oval petals. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, a roundiſh germen below the calix, five ſhort ſtyles, and ſimple ſtigma. PERICARPIUM, a roundiſh ſtriated berry, containing five ſeeds.

The ſpecies are,

[1]ARALIA *Racemoſa*.

*Leafy-ſtalked Herbaceous Canada Aralia.*] Aralia with an upright, ſmooth, branching, leafy ſtem, obtaining three or four feet ſtature, adorned with large leaves, compoſed of many oval ſerrated lobes, and flower-ſtalks riſing from the angles of the leaves, terminated by round umbels of whitiſh flowers.

[2]ARALIA *Nudicaulis*.

*Naked-ſtalked Herbaceous Virginia Aralia.*] Aralia with an upright naked, or leafleſs ſtalk, a yard high, large branching leaves, of two or three diviſions, each diviſion compoſed of five ſerrated lobes, and riſe directly from the root, and between them the ſtalks, crowned by round umbels of whitiſh flowers.

[3]ARALIA *Spinoſa*.

*Thorny Tree-like Virginia Aralia, or Angelica-Tree.*] Aralia with a tree-like branching ſtem, growing ten or twelve feet high, defended by ſtrong ſpines, large, long, decompounded, ſpinous leaves, compoſed of many wings, each wing of many oblong lobes, and large, looſe, greeniſh-yellow umbels of flowers terminate all the branches.

All theſe plants are natives of America, but grow freely here in the full ground.

The appellation of Angelica to theſe plants, is from their ſimilarity of growth, and the young leaves forming a cluſter at the ends of the ſtem and branches, like thoſe on the ſame parts of the Common Angelica.

The *Aralia Racemoſa* and *Nudicaulis* are herbaceous perennials; the roots are fibrous, and creep conſiderably, and the ſtalks riſe annually from the root, produce their large umbels of flowers in June and July, and are ſucceeded by plenty of ſeed in cluſters of ſmall black berries, ripe in September and October.

Theſe two ſpecies aſſuming a large branching majeſtic growth, are proper furniture for the compartments of large ſhrubberies, and to embelliſh thoſe of wilderneſs works, and the borders of wood-walks, &c.

Their propagation is by ſeed, and by dividing their roots.

The ſeed, if ſown in autumn, in a bed of light earth, will riſe freely in the ſpring, and in autumn tranſplant the plants where they are to remain.

By roots they encreaſe exceedingly, which may be parted in autumn when the leaves decay.

The *Aralia Spinoſa*, or Angelica-Tree, is deciduous in leaf. It is a plant of ſingular appearance in ſummer, when cloathed with its large, long, doubly branching, many-lobed leaves, and claims a place in the moſt conſpicuous parts of the ſhrubbery.

It flowers in Auguſt, but rarely perfects ſeed in England.

The propagation of this ſpecies is by ſeed, and by planting pieces of its horizontal roots.

The ſeed is procured from America. Sow it as ſoon as it arrives, in ſpring, in pots of light earth, and cover it half an inch deep, and if they are plunged in a moderate hot-bed, it will facilitate their germination; but in default of this, plunge the pots in a dry warm border, give occaſional light waterings and ſhade in hot ſunny days, and probably the plants will appear the ſame year; but if this is not effected by June, move the pots under a ſhady hedge or wall for the remainder of the ſummer, and in October place them in a garden frame, to have occaſional ſhelter from froſt during winter, in which let them remain until March; then plunge them in a warm border, and if the plants did not come up before, they will now appear, giving water occaſionally, and remove the pots to the ſhade in ſummer, and into a frame again in winter, to continue until the latter end of March; then tranſplant them, ſome ſeparately into ſmall pots, others in a bed of light earth, in a ſheltered ſituation in the nurſery: thoſe planted in the pots are deſigned to be moved to ſhelter in winter, becauſe the ſeedling plants are tender the firſt two or three years; ſome ſhelter ſhould alſo be beſtowed the firſt winter upon thoſe in the full ground, when the froſt is very ſevere.

When theſe plants are three or four years old, or two or three feet high, they may be tranſplanted into the ſhrubbery.

To propagate them by roots, cut off pieces of the horizontal ones in ſpring, and plant them in pots, which plunge in a hot bed, and they will ſend out fibres below, and ſhoots above.

Likewiſe, by ſeparating ſome of the roots from the plant in ſpring, permitting them to remain in the ground, they will alſo ſend up ſeveral ſhoots or ſtems.

ARBOR, a Tree. A perennial plant, riſing with a ſimple, woody, and durable ſtem or trunk, to a great height and ſubſtance.

This definition of a tree is principally the ſubſtance of what naturaliſts advance to diſtinguiſh a tree from a ſhrub, which is ſuppoſed to be of leſſer growth, and for the general part to have ſeveral ſtems; and from herbaceous plants, whoſe ſtems are ſoft, often ſucculent, and moſtly riſe in ſpring, and periſh in autumn, though this is not general.

But in regard to the diſtinction between trees and ſhrubs, it is not univerſally obvious. Nature, ſays Linnæus, has put no limits betwixt trees and ſhrubs; for to ſay that trees are taller than ſhrubs, is in effect ſaying nothing, unleſs a certain fixed immutable ſtandard were previouſly eſtabliſhed. Beſides, every thing reſpecting dimenſions is ſo variable in its nature, and depends ſo much upon difference of climate, ſoil, and culture, that no certain ſtandard or boundary can with propriety be fixed between trees and ſhrubs, ſince the ſame plant, in different countries, often aſſume very different growths; thus the *Arbutus*, and Laurel, in warm climates, grow to large trees; in this country are generally conſidered as ſhrubs.

The only definition therefore that can be made, is, that, for diſtinction ſake, ſhrubs may be conſidered as ſuch, which either riſe with

with ſeveral ſtems from the root, or that the main ſtem divide near the root into ſeveral ſmaller ones. See FRUTEX, *a Shrub.*

ARBOURS.

Theſe are departments in gardens formed with various ſorts of trees and ſhrubs, in ſuch order as to encloſe a certain ſpace, to form a kind of receſs and ſhady retreat from the walks, in the heat of ſummer.

They were in great repute formerly, and were commonly formed of ever-greens, very often of yews, planted very cloſe, the ſides trained erect, ſix, eight, or ten feet high, and the top formed like a vault, or trained arch-ways, over an arched frame or lattice-work, of wood or iron, and arched openings or arcades were curiouſly formed on the ſides, and the whole was ſhorn or clipped annually, to keep them in due order, which often appeared very ornamental, according to the ancient ſtyle of gardening.

Theſe kind of Arbours were alſo often formed of deciduous trees, particularly thoſe of the elm, and ſometimes with hornbeam, beech, and limes, which were conſtantly ſheared every ſummer.

The figure of theſe Arbours, both of the ever-green and deciduous kinds, were either ſquare, hexagonal, octagonal, or round; and their dimenſions were from ten to fifteen feet in width and height; the tops were formed either pavillion, turret, or dome faſhion, and ſometimes terminated by a globe, pyramid, or other figure, formed of the extreme branches.

Covered Arbours or Bowers may be formed very quickly, even in one ſeaſon, with ſeveral ſorts of ſhrubby climbers, ſome of which will advance fifteen or twenty feet in one ſummer. See CLIMBING PLANTS.

When it is deſigned to form an Arbour, it ſhould, if poſſible, be erected upon a ſomewhat riſing ground, for the greater advantage of free air, and to enjoy the proſpect of the garden and adjacent country.

An Arbour is ſometimes formed in the head of a ſingle tree, particularly that of the elm, when the trunk has divided at the height of ten or twelve feet, into ſeveral leſſer ſpreading ſtems, to admit of erecting a ſmall platform between, cutting down the large boughs, and training the pliable branches arch-ways over lattice-work, till thoſe of each ſide meet; ſo continue to ſhear the ſides annually, and the top may either be cut, or permitted to grow up.

Rural Arbours are ſometimes formed thus: plant ſome of the talleſt growing flowering ſhrubs round the inſide, to form the dimenſions of the Arbour; then, on the outſide of theſe, plant others of ſomewhat leſſer growth; ſo continue three or four ranges, diminiſhing gradually in ſtature from the Arbour outward, permitting the whole to take their natural growth; ſo that at a diſtance it will aſſume the appearance of one of the common ſhrubbery clumps.

The bottom of Arbours ſhould be gravelled, and garden chairs placed there in ſummer, which ſhould always be houſed in winter.

ARBUTUS, the Strawberry-Tree.

This genus furniſhes moſt beautiful ever-green ſhrubs for the ſhrubbery, remarkable for producing fine cluſters of ſcarlet fruit, like ſtrawberries, hence they derive the appellation Strawberry-Tree.

Claſs and order, *Decandria Monogynia.*

*Characters*] CALIX is ſmall, five-parted, permanent, and placed under the germen. COROLLA, a ſingle pitcher-ſhaped petal, five-parted, and revolute at the brim. STAMINA, ten ſhort filaments, and bifid antheræ. PISTILLUM, a globular germen, cylindric ſtyle, and thick obtuſe ſtigma. PERICARPIUM, a roundiſh berry of five cells, containing ſmall hard ſeeds.

The ſpecies are,

[1] ARBUTUS *Unedo.*

*Common Arbutus, or Strawberry-Tree.*] Arbutus with an erect tree-like woody ſtem, oblong oval ſmooth leaves, ſawed on the edges, and berries having many ſeeds.

*Varieties of this are,*] Common Arbutus with large oval fruit.——Common Arbutus with round fruit.—Double-bloſſomed Common Arbutus.——Scarlet-flowering Common Arbutus.

[2] ARBUTUS *Andrachne.*

*Andrachne, or Oriental Broad-leaved Arbutus.*] Arbutus with an erect tree-like woody ſtem; oblong, oval, ſmooth leaves, having entire edges; and berries having many ſeeds.

[3] ARBUTUS *Uva Urſi.*

*Uva Urſi, Bear-berry, or Dwarf Arbutus.*] Arbutus with ſhrubby, very branchy ſtalks, about two feet high; oval, thick, ſmooth, entire leaves; greeniſh-white flowers in cluſters at the ends of the branches, and roundiſh berries.

*Varieties.*] *Uva Urſi* with black berries.—*Uva Urſi* with red berries.

All the above ſpecies and reſpective varieties are hardy exotic ever-greens; the two former are of a tree-like growth, and the other is a dwarfiſh ſhrubby plant. They will proſper in any common ſoil of a garden.

They are all cloſely adorned the year round with ſimple leaves, and produce flowers and fruit in ſmall looſe cluſters.

The Common Arbutus and varieties are ſome of the moſt elegant ever-greens of our ſhrubberies; they are natives of Spain, Italy, and ſome parts of Ireland, where they obtain twenty or thirty feet ſtature, with trunks of conſiderable ſubſtance.

Theſe varieties, in this country, often grow twelve or fifteen feet high, aſſuming full and regular heads, and all the young ſhoots a fine red colour, the whole cloſely adorned with moderate-ſized, oblong, ſawed leaves, placed alternate, and the trees are fully garniſhed with them at all ſeaſons, and produce whitiſh flowers in numerous ſmall cluſters annually in October and November, ſucceeded by abundance of ſtrawberry-like fruit; but theſe do not attain maturity in leſs than twelve months, when they aſſume a ſcarlet colour; ſo that thoſe of each year's bloom ripen next year in November, by which means there are annually flowers, and ripe fruit upon the trees at the ſame time; which, together with their numerous leaves on red foot-ſtalks, effects one of the moſt ſingularly beautiful contraſts in nature.

The oval and round fruited varieties are the ſorts moſt commonly cultivated, the former of which rather obtains the largeſt growth, and produces the largeſt flowers and fruit.

The double-bloſſomed kind having only two ſeries of petals; its doubleneſs is not very conſpicuous.

The ſcarlet kind, when in bloom, forms a pretty diverſity, in aſſemblage with the other varieties.

The *Andrachne*, or Oriental Arbutus, aſſumes a larger growth than any of the preceding ſorts, and branches out irregularly; the leaves are large, and with the edges entire, but produces flowers and fruit like the Common Arbutus.

This ſort having fine large leaves, makes a noble appearance at all ſeaſons.

The flowers of all theſe varieties are produced in ſmall looſe cluſters, each ſeparate flower is ſmall, and formed univerſally of a ſingle hollow petal, bellied below, pitcher faſhion; the whole, except the ſcarlet kind, aſſume a greeniſh-white colour, and the fruit ſucceeds the flowers in cluſters.

The fruit are berries, in ſhape, ſize, and colour reſembling large ſcarlet ſtrawberries, though generally much larger, and grow three, four, five, or more in cluſters, remarkably beautiful to appearance, but unpalatable to eat.

The *Uva Urſi* is a ſmall buſhy ſhrub, a native of the mountainous parts of the continent of Europe, and is retained in many gardens for the ſake of variety.

*Uſe in Gardens, Propagation, &c.*

All the varieties of the Common Arbutus and *Arbutus Andrachne*, are ſome of the fineſt ever-greens that can be ſeen, and are well adapted to occupy the moſt conſpicuous places in ſhrubberies, either in aſſemblage towards the fronts of clumps, or to be placed detached on graſs ground.

In whatever mode of planting it is deſigned to employ them, place them ſo much detached as to appear conſpicuous at all times, and permit them to take their own natural growth.

The beſt ſeaſon for tranſplanting all the ſorts, is the end of September, October, and beginning of November, or in March and April.

The propagation of all the ſpecies is effected moſt commonly by ſeed; they will alſo ſometimes grow by layers and cuttings, though rather reluctantly; but the ſeed grows freely, and from which the handſomeſt plants are always obtained. Obſerve however, that, to continue the double-bloſſomed and ſcarlet kinds with certainty, it muſt be effected either by layers, cuttings, grafting, or inarching; for theſe varieties will not retain their difference from ſeed.

From the ſeed of either the common oval and round fruited kinds, ſome of both ſorts may be expected; that of the former is rather to be preferred for ſowing.

The berries containing the ſeed may be had of the nurſerymen in October, November, and December; and the ſeed may either be then ſown in pots, and ſheltered in a frame all winter, or may be preſerved in dry ſand until March, and then ſown in pots of light earth, and covered about a quarter of an inch deep; then, if the pots are plunged in a hot-bed, it will ſo greatly forward the germination of the ſeed that the plants will riſe in a month or ſix weeks, when they muſt have plenty of air, moderate waterings, and by de-

grees

grees inured to the full air, when the pots ſhould be plunged in the common ground until October, and then placed in a green-houſe or frame, to have ſhelter from froſt, till March; at which time it is adviſeable to tranſplant the ſeedlings ſingly in ſmall pots, which, if directly plunged upon a ſlender hot-bed, ſhielded and ſhaded occaſionally with mats, giving moderate waterings, they will quickly take root and ſet to growing, when the pots may be plunged in a bed of common earth in a ſheltered place, to remain two or three years, indulging the plants with larger pots, and protection from ſevere froſt, till they are about two feet high; then tranſplant them, with the balls of earth about their roots, into the full ground.

To propagate them by layers, it muſt be performed on the young ſhoots, which rarely emit roots in leſs than two years.

Cuttings will emit roots by the aid of heat. Plant a number of the ſhort young ſhoots in pots, and plunge them in a ſubſtantial hot-bed of tan or dung.

Inarching or grafting them is performed in the uſual way, upon ſtocks of any of the varieties.

ARCTOTIS.

This genus conſiſts of four ſhrubby perennials, of tall and very branching growth, and an herbaceous acaulis plant, all flowery exotics of the green-houſe.

Claſs and order, *Syngeneſia Polygamia Neceſſaria.*

*Characters.*] CALIX, is a round, imbricated, ſcaly cup. COROLLA, is compound and radiated; the middle compoſed of numerous male, funnel-ſhaped, five-parted, reflexed florets, and many long, flat, female florets compoſe the border or radius. STAMINA, in each male floret are five filaments, having ſhort antheræ. PISTILLUM, in the female florets, a trigonous downy germen, ſimple ſtyle, and two oval ſtigma. PERICARPIUM none, and a ſingle ſeed in each female floret.

The ſpecies are,

[1]ARCTOTIS *Aſpera.*

*Rough-leaved Golden Arctotis.*] Arctotis with an upright, branching ſtalk; oblong, deeply ſinuated, winged-like, hairy leaves; the ſegments oblong and indented, and large golden yellow flowers, having a fertile radius.

[2]ARCTOTIS *Anguſtifolia.*

*Narrow-leaved Arctotis.*] Arctotis with an erect, branching ſtalk; narrow, ſpear-ſhaped, ſtiff, entire leaves, indented on the ſides, and pale yellow flowers, having a fertile radius.

[3]ARCTOTIS *Calendula.*

*Sea Ragwort-leaved Arctotis.*] Arctotis with an erect, branching ſtalk; oval, lyre-ſhaped, indented leaves, with blackiſh denticles, and large ſulphur-coloured flowers, having a ſterile radius.

[4]ARCTOTIS *Plantaginea.*

*Plantain-leaved Arctotis.*] Arctotis with an upright, branching ſtalk; ovate-ſpear-ſhaped, indented, nervous, running leaves, embracing the ſtalk; and large golden yellow flowers, having a fertile radius.

[5]ARCTOTIS *Acaulis.*

*Stalkleſs Dwarf Arctotis.*] Arctotis without ſtalk, lyre-ſhaped, ſinuated leaves from the root, the foot-ſtalks of the flowers riſe between the leaves, ſupporting large golden flowers.

The four firſt ſpecies obtain four or five feet ſtature, having erect, thick, ſhrubby-like, perennial ſtems, which divide into many luxuriant tender branches, terminated by large, compound, radiated, yellow flowers, appearing in ſummer, and often continue in ſucceſſion during autumn and winter, and make a pretty appearance.

The *Arctotis Acaulis* is a low plant, the flower-ſtalks rarely exceed ſix inches in height, but ſupport fine large radiated flowers in April or May, and often afford ripe ſeeds.

They are all exotics of Africa, and require the protection of a green-houſe in winter, ſo muſt always be kept in pots.

The propagation of the ſhrubby ſorts is eaſily effected by cuttings of the branches or ſhoots any time the beginning of ſummer, either in pots, or a bed of light earth, giving occaſional ſhade and water, and they will be rooted in ſix or eight weeks, when they ſhould be planted in ſeparate ſmall pots, and managed as other green-houſe plants.

The dwarf ſort may be raiſed from ſeed in ſpring, and by ſlips from the roots.

ARISTA, the awn, or ſharp beard or point iſſuing from the huſk or ſcaly flower-cup of the graſſes, as that of the common barley and other corn.

ARISTOLOCHIA, Birthwort.

This genus comprehends herbaceous perennial exotics of the common ground and green-houſe, adorned with heart-ſhaped leaves, and monopetalous tubular flowers, retained in our gardens for variety, and are alſo eſteemed for their eminent virtues in medicine, and are accounted ſovereign in child-birth, as the name imports.

Claſs

Claſs and order, *Gynandria Hexandria.*

*Characters.*] CALIX none. COROLLA is monopetalous, tubular, and irregular, the baſe is globular, and is extended above into a cylindrical tube ſpreading at the brim, where the lower part is ſtretched out like a tongue. STAMINA, no filaments, but ſix antheræ joined to the under part of the ſtigma. PISTILLUM, an oblong triangular germen under the corolla, no ſtyle, but a roundiſh ſix-parted ſtigma. PERICARPIUM, a large oblong capſule of ſix cells, filled with depreſſed ſeeds.

The ſpecies that demand attention are the following.

The firſt four are hardy, herbaceous, perennial-rooted plants, with annual ſtalks.

[1]ARISTOLOCHIA *Rotunda.*

*Round-rooted Trailing Birthwort.*] Ariſtolochia with a roundiſh root; infirm trailing ſtalks, two feet long; heart-ſhaped roundiſh leaves, ſitting cloſe; and blackiſh-purple ſolitary flowers.

[2]ARISTOLOCHIA *Longa.*

*Long-rooted Trailing Birthwort.*] Ariſtolochia with a long carrot-ſhaped root; infirm trailing ſtalks, eighteen inches long; heart-ſhaped blunt leaves, having foot-ſtalks; and purpliſh ſolitary flowers.

[3]ARISTOLOCHIA *Serpentaria.*

*Virginia Snake-root.*] Ariſtolochia with infirm, flexible, procumbent ſtalks, a foot and half long; heart ſhaped, oblong, plane leaves; and recurved, reddiſh, ſolitary flowers.

[4]ARISTOLOCHIA *Clematitis.*

*Upright Heart-leaved Birthwort.*] Ariſtolochia with very creeping roots; erect firm ſtalks, eighteen inches high; heart-ſhaped leaves, having long foot-ſtalks; and pale yellow flowers in cluſters.

The three following are perennial-ſtalked exotics of the green-houſe.

[5]ARISTOLOCHIA *Sempervivens.*

*Ever-green Trailing Birthwort of Crete.*] Ariſtolochia with infirm, angular, trailing ſtalks, eighteen inches long; heart-formed, oblong, waved leaves; and long, recurved, dark purple, ſolitary flowers.

[6]ARISTOLOCHIA *Piſtolochia.*

*Piſtolochia, or Small Ramoſe-ſtalked Birthwort.*] Ariſtolochia with infirm branching ſtalks, heart-ſhaped ſlightly crenated leaves, having foot-ſtalks, and ſolitary flowers.

[7]ARISTOLOCHIA *Arboreſcens.*

*Shrubby Upright Virginia Birthwort.*] Ariſtolochia with ſhrubby erect ſtalks, two feet high; heart-formed ſpear-ſhaped leaves, and ſolitary flowers.

The four firſt ſpecies are hardy, have perennial roots, but the ſtalks are renewed annually in ſpring; which, of the firſt, ſecond, and third ſorts, if not ſupported, proſtrate themſelves upon the ground; but the *Ariſtolochia Clematitis* ſtand erect: all of which are adorned with the leaves in alternate order, and flowers proceeding from the ſides of the ſtalks at the angles of the leaves, in June and July, ſucceeded by ripe ſeed in autumn.

For purpoſes in gardens, theſe four ſorts are conſidered chiefly as plants of variety, or for obſervation, for as flowering plants they cut no great figure.

As medical plants they are poſſeſſed of eminent virtues, being very ſalutary in many diſorders, particularly the roots of the *Ariſtolochia Rotunda* and *Ariſtolochia Longa*, which are alſo remarkable for their drawing properties, inſomuch that a poultice of them will extract thorns or ſplinters from the fleſh in any part of the body; and the root of the *Serpentaria* or Snake-root is a cure for the bite of the rattle-ſnake of America, and all other noxious ſerpents and venomous animals: theſe, as well as the others, are efficacious in many other caſes. They are imported from abroad to ſupply the ſhops, for they are not cultivated here in ſufficient quantity for general uſe, though from ſeed a few plants may be eaſily obtained in our gardens.

The Ever-green *Ariſtolochia*, the *Piſtolochia*, and Shrubby Virginia Birthwort, are ſmall exotic perennials of the green-houſe, durable in root and ſtalks; the two former being of very infirm and flexible growth, require ſupport; but the ſtalks of the other, being more ſhrubby and firm, ſupport themſelves erect; all of which produce flowers ſingly from the angles of the leaves in ſummer, but rarely any ſeed in England.

The flower of all the ſorts is formed of a ſingle hollow, tubular, irregular petal. See the *Characters.*

*Propagation.*

The propagation of the three firſt ſorts is by ſeed ſown in autumn, ſoon after they are ripe, i. e. in September or October, in pots of light earth, which muſt be placed in a garden-frame to have occaſional protection from froſt, and in ſpring the plants will appear; but if the pots are plunged in a moderate hot-bed in March, it will forward them exceedingly, obſerving to inure them by degrees to the

the full air, giving water during ſummer, and ſhelter of a frame in winter, and next ſpring tranſplant them, ſome into a warm border, and ſome in ſmall pots, to have another winter's occaſional ſhelter, which, in ſpring after, may alſo be turned out into the common ground.

The *Ariſtolochia Clematitis* multiplies exceedingly by its creeping roots, by which it may be encreaſed at almoſt any ſeaſon.

The green-houſe kinds may be propagated by ſeeds procured from abroad, and ſown in pots of light earth, and plunged in a hot-bed in March; they may alſo be encreaſed by ſlips of the roots in ſpring, likewiſe by cuttings, particularly the Shrubby Birthwort; all of which, after being raiſed in ſpring and ſummer, muſt be potted in autumn, and houſed every winter.

ARMA, Arms, Armature, or Offenſive Weapon, or Armour of Plants, intended by nature, ſay naturaliſts, to keep off naked animals that would approach to hurt them.

There are different ſpecies of Armour with which plants are furniſhed, and are by botaniſts called, *Aculeus*, prickles, ſuch as thoſe of the roſe and raſpberry, &c. *Spina*, ſpine, or thorns, as the hawthorn, buckthorn, falſe acacia, &c. *Furcæ*, forks, ſpecies of prickles, conſiſting of two or three prongs, as berberry, fig, marigold, &c. *Stimula*, ſtings, as nettle, &c. See ACULEUS, SPINA, FURCÆ, and STIMULA.

AROMATICÆ *Planta*. Aromatic Plants are odoriferous, or of a ſtrong, fragrant, agreeable ſmell and taſte, generally warm and cordial; they are chiefly herbaceous, and their virtue reſides in the leaves.

Several Aromatics are in great eſteem, both for kitchen and medical purpoſes.

The principal ſorts are,

Summer Savory—Winter Savory—Hyſſop—Thyme—Sweet, or Knotted Annual Marjoram—Winter, or Perennial Pot Marjoram—Red or Common Sage—Green Sage—Sage of Virtue—Baum—Spear-mint—Peppermint—Pennyroyal—Clary—Lavender—and Roſemary.

All theſe Aromatics are ſo uſeful in the œconomy of domeſtic affairs, that they ſhould have places in every kitchen-garden, and their culture is remarkably eaſy. See their reſpective genera.

To the above may be added, Baſil, Chervil, Coriander, Dill, Fennel, and Tanſey.

For other Aromatics, ſee MEDICAL PLANTS, POT-HERBS, and VERTICILLATÆ.

ARTEMISIA, Mugwort, comprehending alſo the ſpecies of *Abſinthium*, or Wormwood, and *Abrotanum*, the Southernwood.

This genus is very comprehenſive, and retains both herbaceous perennials and ſhrubby plants of the common ground and greenhouſe, for medical uſe and variety in gardens, adorned principally with finely divided leaves, and ſmall compound flowers, of no beauty, in ſpikes or cluſters.

Claſs and order, *Syngeneſia Polygamia Superflua*.

*Characters.*] Compound flowers. CALIX, the general cup roundiſh and ſcaly. COROLLA, many hermaphrodite florets compoſe the middle, and females the border. STAMINA, in each hermaphrodite floret five filaments. PISTILLUM, a germen and ſtyle in the florets of both ſorts, and bifid ſtigma. PERICARPIUM none, a ſingle naked ſeed ſucceed each germen.

There are upwards of twenty ſpecies, thoſe cultivated for uſe and ornament are,

[1]ARTEMISIA *Vulgaris*.

*The Common Mugwort.*] Artemiſia with pinnatifid, many-parted, plain leaves, downy underneath, and erect firm ſtalks riſing among the leaves, two feet high, each terminated by a long ſimple ſpike of ſmall purpliſh flowers; the radius compoſed of five florets.

*Varieties of this.*] Common Plain-leaved Mugwort.—Silver Striped-leaved Common Mugwort.—Gold-ſtriped Mugwort.

[2]ARTEMISIA *Abſinthium*.

*Abſinthium, or the Common Wormwood.*] Artemiſia with compound, many-parted, finely divided, whitiſh leaves; ſhrubby ſtalks growing two feet high, cloſely adorned with leaves, and globular heads of flowers, hanging from the ſides of the ſtalks.

[3]ARTEMISIA *Pontica*.

*Pontic, or Roman Wormwood.*] Artemiſia with multi-parted, very finely divided leaves, hoary underneath, herbaceous ſtalks, growing a foot and half long, covered with leaves, and globular heads of yellow flowers, nodding from the ſides of the ſtalks.

[4]ARTEMISIA *Maritima*.

*Sea Wormwood.*] Artemiſia with multiparted, divided, very downy leaves, ſhrubby ſtalks, two feet high, adorned with leaves, and drooping alternate ſpikes of flowers from the ſides of the branches.

[5]ARTEMISIA *Arboreſcens*.

*Tree*

*Tree Wormwood.*] Artemiſia with an erect, woody, branching ſtem, grows ſix feet high; leaves compoſed of multifid, linear, very hoary, whitiſh ſegments; and flowers collected into roundiſh heads at the ends of the branches.

6 ARTEMISIA *Abrotanum.*

*Abrotanum, or Common Southernwood.*] Artemiſia with ſhrubby, erect, very branchy ſtalks, three feet high; fine branchy, briſtly, odoriferous leaves, and all the ſtalks and branches terminated by long ſpikes of flowers in autumn.

7 ARTEMISIA *Dracunculus.*

*Tarragon.*] Artemiſia with ſpear-ſhaped, entire, ſmooth leaves, and annual ſhoots.

The flowers of all theſe ſpecies are compound (ſee the *Characters*), very numerous, though ſmall, and of no beauty.

The *Artemiſia Vulgaris* and Common Wormwood are wild inhabitants of uncultivated places, by road ſides, bye lanes, banks, and under walls and hedges about country villages; but being efficacious in medicine, are often cultivated in gardens, where they are alſo ſometimes admitted as plants of variety or obſervation, particularly the variegated Mugworts.

The Roman Wormwood is an exotic of Hungary and Thrace, but is retained in our gardens for variety and uſes in medicine.

The Sea Wormwood inhabits the ſea-ſhores of England, and is ſometimes admitted in gardens for variety, and as a medical plant.

The above four ſpecies flower in June, July, and Auguſt, and ripen abundance of ſeed.

They may be raiſed abundantly from ſeed, in almoſt any ſituation or ſoil; and by ſlips, cuttings, and by parting their roots in autumn or ſpring.

The Tree Wormwood is an exotic of Italy; it is a hoary ever-green, and conſidered here principally as a green-houſe plant, although it will often ſucceed in the full ground, and by its hoary whitiſh leaves make a pretty appearance any where. It is propagated by cuttings in a ſhady border, in April, May, and June; and in autumn ſome ſhould be potted for ſhelter in winter, and ſome may ſtand to take their chance in the full ground.

The Southernwood is one of our ſmalleſt hardy deciduous ſhrubs, will grow any where, and affords variety in common borders and the fronts of ſhrubbery clumps.

This little ſhrub is in great repute about London, and the gardeners about that city raiſe vaſt quantities of them annually, training them about a foot high, with roundiſh buſhy heads, for which they find a ready ſale in Covent-garden and Newgate markets; the inhabitants buying them to place in their court-yards, balconies, and windows, in aſſemblage with other hardy plants that bear the ſmoak.

It is propagated with facility by ſlips and cuttings of its branches, in a ſhady border in April; and as many ſmall ſtems riſe from the root, theſe may be ſlipped or divided into as many parts as are furniſhed with the leaſt fibre, and plant them in an open bed in rows nine inches diſtance, they will form handſome plants after one ſummer's growth.

The Tarragon, being warm and fragrant, is uſed as a ſallad herb; it is perennial, and propagated by its creeping roots, or cuttings of its young ſhoots in April and May.

ARUM, Wake-Robin, or Cuckow-Pint.

The plants are herbaceous perennials of the common borders and ſtove, moſtly acaulis, i. e. no ſtalk, but riſe with large leaves directly from the root; though ſome are cauliſcent, and between the leaves riſe a large ſpadiceous, apetalous, club-ſhaped flower, of ſingular ſtructure.

Claſs and order, *Gynandria Polyandria.*

*Characters.*] CALIX, is a large monophyllous ſpatha, compreſſed in the middle, and coloured within. COROLLA, no petals, but a large ſimple, club-ſhaped, coloured ſpadix, upon which are placed the germina. STAMINA, no filaments, but numerous four-ſquared antheræ ſitting cloſe to the ſpadix, with a double row of hair-like nectaria between them. PISTILLUM, numerous oval germina furround the ſpadix, no ſtyles, but many bearded ſtigma. PERICARPIUM, many globular berries of one cell, and many roundiſh ſeeds.

There are twenty or thirty ſpecies, one of which grows naturally in England; all the others are exotics of many different parts of the world, ſeveral of which are retained in our gardens: theſe are,

1 ARUM *Maculatum.*

*Common Spotted Arum.*] Arum without ſtalk, halbert-ſhaped entire leaves from the root, and among them riſes a ſhort foot-ſtalk, crowned by a large club-ſhaped ſpadix.

*Varieties of this.*] Common Arum with dark ſpotted leaves——with white ſpotted leaves——with white and black ſpotted leaves——with entirely green leaves.

2 ARUM

[2]ARUM *Italicum.*

*Italian White-veined-leaved Arum.*] Arum without ſtalk; large, halbert-ſhaped, white-veined leaves, running out to a ſharp point, riſe from the root a foot and half high, on long foot-ſtalks, and a large erect whitiſh ſpatha riſes between the leaves, near a foot in height.

[3]ARUM *Ariſarum.*

*Ariſarum, or Broad-leaved Friar's Cowl.*] Arum without ſtalk; heart-ſhaped oblong leaves from the root, and between them is the flower, growing cloſe to the ground, having a bifid ſpatha and incurved ſpadix.

[4]ARUM *Dracunculus.*

*Dracunculus, or Common Spotted Dragon.*] Arum with an erect thick ſtalk, a yard high, finely ſpotted like a ſnake's belly, dividing at top into palmated leaves, having ſpear-ſhaped, equal, entire lobes, and between them proceed a long erect purple ſpatha, protruding a large erect, club-ſhaped, purple piſtil, or ſpadix, ſhorter than the ſpatha.

[5]ARUM *Colocaſia.*

*Colocaſia, or Ægyptian Arum.*] Arum without ſtalk; large target-ſhaped ovate leaves from the root, two-parted at the baſe, and with ſinuated waved borders.

[6]ARUM *Trilobatum.*

*Trilobate, or Three-lobed Indian Arum.*] Arum without ſtalk; leaves from the root, compoſed of three arrow-pointed lobes, and between them riſe the flower on a ſhort foot-ſtalk, having a long ſpatha and ſcarlet ſpadix.

[7]ARUM *Arboreſcens.*

*Tree American Arum, or Dumb Cane.*] Arum with an erect jointed ſtalk, ſix feet high, arrow-ſhaped leaves in cluſters at top, and the flowers riſe between the leaves in long green ſpathæ, ſitting cloſe to the ſtem.

All theſe plants are herbaceous, perennial in root, but moſtly annual in leaf and ſtalk, which riſe in ſpring, flower in April, May, and June, ripen ſeeds ſoon after, and die to the ground in autumn.

The roots are moſtly thick, fleſhy, and multiply conſiderably.

The leaves are large and broad, and ſome are very beautiful.

The flower-ſtalks of all the ſorts ſupport a ſingle ſpatha or ſcabbard, protruding the flowers, having no petals, but a large red or purple ſpadix or piſtillum, elevated like a column, which is ſucceeded by a cluſter of berries, containing the ſeeds; but very few of theſe plants ripen ſeed in this country.

The *Arum Maculatum* is a reſident of our woods and banks under hedges, but the plants are admitted for variety in pleaſure grounds, in aſſemblage with the other hardy ſorts; but the ſpotted kinds of them have moſt merit, and form an agreeable diverſity.

The ſecond and third ſorts are exotics, though of hardy growth, and have been long entertained in curious gardens for their ſingular appearance.

The *Arum Dracunculus* is a hardy plant, of ſo ſingular and auguſt appearance, that it deſerves a place in every collection of herbaceous perennials, although the ſtrange ſingularity of its maculated ſnake-like ſtem is diſagreeable to ſome, and its flower emits a diſagreeable odour.

All the above four ſpecies ſucceed in any of the common borders.

The fifth, ſixth, and ſeventh ſorts are exotics of hot climates, and are preſerved here in ſtoves as plants of curioſity.

*Propagation.*

The propagation of all the ſorts is eaſily accompliſhed, and moſtly by parting the roots.

The firſt ſix ſorts encreaſe greatly by their roots, and the off-ſets may be ſeparated, or the whole root divided in autumn, after they have flowered, or early in ſpring; thoſe of the hardy kinds are to be planted in the borders, and the tender ſorts in pots, and retained in the ſtove.

Thoſe of the hardy ſorts that ripen ſeeds may alſo be raiſed by ſowing them in pots in autumn, and if thoſe are plunged in a hot-bed in March, juſt to bring up the plants, it will forward them greatly.

The Tree Arum is propagated by cuttings of its ſtalk, three joints in length, which, after having lain four or five weeks, till the cut part is healed, plant them ſeparately in pots, and plunge them in the ſtove.

ARUNDO, the Reed.

The plants are moſtly herbaceous perennials, ſome of which riſe with herbaceous ſtalks, from three to twelve feet high; others have tree-like ſtems, advancing with amazing rapidity of growth to thirty or forty feet in height.

Claſs and order, *Triandria Digynia.*

*Characters.*] CALIX is a glume, or huſky ſcale of two valves. COROLLA, two acuminated huſky valves, downy at the baſe. STAMINA, three filaments, and horned antheræ. PISTILLUM, a germen, two reflexed ſtyles,

and ſimple ſtigma. PERICARPIUM none, and the ſeed is ſingle.

The plants are of the graſs tribe, and produce their flowers in ſpikes, which have no beauty.

The ſpecies of note are,

[1]ARUNDO *Phragmites.*

*The Common Marſh Reed.*] Arundo with ſlender erect ſtalks, ſix or eight feet high, terminated by looſe panicles of flowers, growing five in each cup.

[2]ARUNDO *Donax.*

*Donax, or Portugal Reed.*] Arundo with large erect ſtems, ten or twelve feet high, terminated by diffuſe panicles of flowers, growing three in each cup.

[3]ARUNDO *Verſicolor.*

*Variegated Indian Reed.*] Arundo with erect firm ſtalks, four or five feet high, adorned with variegated leaves, and terminated by diffuſe panicles of flowers.

[4]ARUNDO *Bamboa.*

*Bambu-Cane, or Great Indian Reed.*] Arundo with a very large erect ſtem, growing thirty or forty feet high, adorned with very large, long, and pointed leaves, and ſeſſile ſpikes, having many flowers in a cup.

The firſt three ſorts are hardy, but the Bambu-Cane cannot live in our climate, unleſs it is indulged with a place in the hot-houſe.

The *Arundo Phragmites* or Common Reed is an inhabitant of our river ſides, and ſtanding waters, all over the kingdom, ſo is rarely admitted in gardens. This ſpecies growing in great abundance in marſhy ſituations, and the roots ſending up an annual crop of ſtalks, are, in many places, conſtantly cut in autumn, and tyed in bundles for ſale, being uſeful for various purpoſes, ſuch as thatching houſes, &c. and among gardeners, they are employed in forming ſhelters, called reed-hedges, being cheap, and quickly made ſhelter for young and tender plants in winter, both in nurſeries and large kitchen grounds, ſee REED-HEDGES, and for which, and many other uſes, great quantities are brought in barges up and down the river Thames to London, where they may be purchaſed in the warehouſes contiguous to the river.

The Portugal or Spaniſh Reed is retained in many of our gardens for its ſingular lofty growth; it proſpers in any common ſoil of a garden: the ſtalks riſe annually in ſpring, frequently from three to twelve from the ſame root; they are large and jointed, and attain ten or twelve feet ſtature in three or four months, adorned with large long leaves at the joints, but it rarely flowers here.

The Variegated Indian Reed, is, in its general habit, the ſame as the Portugal kind, only the whole plant is of much ſmaller growth.

Both theſe ſorts are eaſily propagated by dividing their roots in February or March, before they begin to ſhoot forth new ſtalks, and the ſlips will ſhoot the ſame ſeaſon, though not with vigour until the ſecond or third year.

The ſtalks may be cut down every autumn, and uſed as walking-ſticks, &c.

The *Arundo Bamboa* is a native of both Indies, and is retained here in our ſtoves as a plant of ſingularity; in its native ſoil it grows forty feet high, and attains conſiderable ſubſtance, and even in our hot-houſes, where there is room, they often grow at the aſtoniſhing rate of twenty feet in ſix weeks; the ſtems of theſe Canes are uſed here for walking-ſticks, fiſhing-rods, &c. but in India the large ones are employed for various purpoſes, and the leaves being very large and long, are ſkewered together to form mats for package, ſo arrive here in tea-cheſts, &c. and we often ſee them in the ſtreets thrown out of the grocer's ſhops.

The propagation of this Cane is eaſily accompliſhed by taking off ſlips from the roots in February or March, planting them in large pots, which plunge in the bark-bed in the hot-houſe, where they are always to remain.

As they grow naturally in marſhy places, they muſt be plentifully watered.

ASARUM, *Aſarabacca.*

The plants are low herbaceous perennials, adorned with ſimple leaves and apetalous flowers, which riſe but very little from the ground, and are retained in gardens for variety, and ſome as medical herbs.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX is monophyllous, bell-ſhaped, coloured, three-parted, and reflexed at the brim. COROLLA none. STAMINA, twelve filaments, and oblong antheræ. PISTILLUM, a germen, cylindric ſtyle, and ſix-parted ſtigma. PERICARPIUM, a leathery capſule of ſix cells, having oval ſeeds.

The ſpecies are,

[1]ASARUM *Europæum.*

*European, or Common Engliſh Aſarabacca.*] Aſarum with kidney-ſhaped, bluntly two-pointed, ſhining leaves, riſing from the root

on

on ſhort foot-ſtalks, and among them purple flowers, cloſe to the ground.

[2]ASARUM *Canadenſi.*

*Canada Aſarabacca.*] Aſarum with large kidney-ſhaped, pointed, hairy leaves from the root, on long foot-ſtalks, and among them greeniſh flowers, ſitting cloſe to the ground.

[3]ASARUM *Virginicum.*

*Virginian veined-leaved Aſarabacca.*] Aſarum with heart-ſhaped, rounded, ſmooth, veined, and ſpotted leaves from the root, on very long foot-ſtalks, and dark purple flowers elevated among the leaves.

They are all hardy, herbaceous, fibrous-rooted perennials, whoſe leaves and flowers riſe directly from the root, and grow near the ground; the flowers of the firſt and ſecond ſorts having very ſhort foot-ſtalks, are inſufficient to elevate them above the leaves, but thoſe of the third being much longer, the flowers are more conſpicuous.

They flower in May, and ripen ſeeds in Auguſt.

The flowers are univerſally apetalous, ſo conſiſt only of the bell-ſhaped coloured calix. See the *Characters.*

Conſidered as plants of ornament, they make no great figure; but as plants of ſingularity in their flowers, mode of flowering, &c. they merit places in the front of borders, and other compartments, among plants of loweſt growth.

As medicinal plants, the Common Aſarum is the ſort preſcribed, and is efficaceous in many diſorders.

The propagation of all theſe three ſpecies is by parting their roots in autumn or ſpring.

ASCLEPIAS, Swallow-Wort, comprehending alſo ſeveral ſorts of Dog's-Bane, removed by Linnæus from the genus *Apocynum.*

This genus furniſhes a choice collection of tall flowery perennials, both herbaceous and ſhrubby, of the full ground, green-houſe, and ſtove, obtaining from two to ſeven feet ſtature, ornamented with ſimple leaves and monopetalous flowers, in cluſters.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX is monophyllous, and five-parted at the brim. COROLLA, a ſingle petal cut into five oval ſegments, and five horned nectaria encompaſs the fructification. STAMINA, five ſcarcely viſible filaments, and five antheræ ſituated between the nectaria. PISTILLUM, two oval germina, two ſhort ſtyles, and ſingle ſtigmas. PERICARPIUM, two large oblong ſwelling pods, having compreſſed ſeeds.

The following ten ſpecies are thoſe chiefly known in the Engliſh gardens; the firſt eight of which are herbaceous and hardy.

[1]ASCLEPIAS *Vincetoxicum.*

*Vincetoxicum, or Common White Swallow-Wort.*] Aſclepias with erect jointed ſtalks, growing two feet high; oval leaves by pairs, bearded at the baſe; and white flowers in branching cluſters near the top of the ſtalks.

[2]ASCLEPIAS *Nigra.*

*Black-flowered Swallow-Wort.*] Aſclepias with ſlender ſtalks, riſing three feet high, twining at top; oval ſpear-ſhaped oppoſite leaves, by pairs, bearded at the baſe; and black flowers in branchy cluſters from the upper part of the ſtalks.

[3]ASCLEPIAS *Lutea.*

*Yellow Swallow-Wort.*] Aſclepias with infirm ſtalks, two feet long, narrow oval acute leaves, and yelloviſh flowers in ſimple cluſters near the top of the ſtems.

[4]ASCLEPIAS *Syriaca.*

*Syrian Broad-leaved Purple Dog's-Bane.*] Aſclepias with very creeping roots, ſending up ſtrong erect ſimple ſtems, four feet high, having large oval thick leaves, by pairs, downy underneath, and purpliſh flowers in nodding cluſters near the top of the ſtems.

[5]ASCLEPIAS *Purperaſcens.*

*Purpliſh Carolina Dog's-Bane.*] Aſclepias with erect ſtalks growing a yard high, adorned with oval leaves, by pairs, hairy underneath, and the ſtems terminated by erect umbels of purpliſh flowers, having declinated nectaria.

[6]ASCLEPIAS *Verticillata.*

*Whorled-leaved Maryland Aſclepias.*] Aſclepias with erect ſlender ſtems, two feet high, narrow revolute leaves placed in whirls round the ſtalk, and the ſtalks crowned by umbels of white flowers.

[7]ASCLEPIAS *Decumbens.*

*Declinated Orange-coloured Virginia Dog's-Bane.*] Aſclepias with declinated hairy ſtalks, a foot and half long, garniſhed with oval hairy oppoſite leaves, and the ſtalks terminated by compact umbels of orange-coloured flowers.

[8]ASCLEPIAS *Tuberoſa.*

*Tuberous-rooted Erect Orange-coloured American Dog's-Bane.*] Aſclepias with a large tuberous root, erect divaricating hairy ſtalks, about two feet high, adorned with ſpear-ſhaped hairy alternate leaves, and the ſtalks ſurmounted by umbels of orange-coloured flowers.

The following is a green-houſe plant.

9 ASCLEPIAS *Fruticoſa.*

*Shrubby Aſclepias.*] Aſclepias with ſhrubby erect very branchy ſtems, growing ſix or eight feet high, all the branches cloſely garniſhed with long ſpear-ſhaped ſmooth leaves, and white flowers in ſingle looſe umbels, on long foot-ſtalks, from the ſides of the branches.

The following is a ſtove plant.

10 ASCLEPIAS *Curaſſavica.*

*American Scarlet Aſclepias.*] Aſclepias with erect ſingle ſtems, riſing five or ſix feet high, ſpear-ſhaped ſmooth oppoſite leaves, having foot-ſtalks, and flowers from the upper parts of the branches, in erect ſingle umbels, having ſcarlet petals, and ſaffron-coloured nectaria.

All theſe plants are exotics principally of America, and are retained here in moſt of our curious gardens as plants of ornament.

The firſt eight ſpecies are hardy herbaceous perennials, with fleſhy fibrous abiding roots; but the ſtalks are annual, they riſing in ſpring, attain their full growth in three or four months; flower in June, July, and Auguſt; perfect ſeeds in September, and ſoon after the whole dies down to the ground.

Ripe ſeed however is only to be expected here principally from the firſt four ſorts, and ſometimes from the *Aſclepias Decumbens* and *Tuberoſa.*

The above eight hardy ſpecies are elegant furniture for the pleaſure ground; they will ſucceed in the common borders, and may be employed in the embelliſhment of the ſhrubbery clumps, diſpoſing them towards the front, and their general culture is the ſame as other hardy herbaceous perennials. See HERBACEOUS PLANTS.

Obſerve however that as the two Orange Dog's-Banes are ſometimes affected by ſevere froſt, it is eligible to allow them a warm dry ſituation, alſo to pot ſome of each for ſhelter in winter.

The *Aſclepias Fruticoſa*, and the American Scarlet Aſclepias are tender exotics; the former that of the green houſe, and the latter of the ſtove. Theſe are elegant plants, and remarkably beautiful when in flower, which is generally from about Midſummer until October, and they frequently afford us ripe ſeed for their propagation. They muſt always be cultivated in pots, and the former ſort placed in a green houſe in winter, and the other muſt be retained always in the ſtove; and as they are milky plants, ſhould be very ſparingly watered in winter.

The flowers of all theſe ten ſpecies are produced in umbellated cluſters; each ſeparate flower is rather ſmall, and formed of one leaf or petal, and five horned nectaria. See the *Characters.*

*Propagation of all the Species.*

The firſt ſix ſpecies are propagated plentifully by dividing the roots in autumn, when the ſtalks decay; or in ſpring, before new ones begin to ſhoot forth.

They may alſo be raiſed from ſeed in a bed of common earth, in March and April.

The ſeventh and eighth ſorts are propagated principally by ſeeds in pots of light earth in ſpring, plunging them in a hot-bed, and when the plants appear, inure them by degrees to the full air; then prick them upon a ſheltered border, ſix inches apart, giving occaſional ſhade and water; alſo ſhelter from froſt in winter by covering the bed with litter or mats, and in March tranſplant them where they are to remain.

The Shrub Aſclepias is propagated by ſeed and by cuttings. By ſeed, ſow them in pots of light compoſt in March or April, and plunge them in a hot-bed, and when the plants are three inches high, prick them in ſeparate ſmall pots, giving ſhade and water. By cuttings, plant them in pots any time from March till Midſummer; move them to the ſhade, and give water, and in autumn they will be rooted, when they are to be ſeparately potted, moving the whole to the green-houſe in October.

The tenth ſort is alſo raiſed from ſeed in a hot-bed; when the plants are three inches high, prick them in ſeparate pots, and plunge them directly in the hot-houſe.

ASHES, for Manure to Land.

Aſhes, as manure or dreſſing to land, may be applied to conſiderable advantage in cold, heavy, inactive ſoils.

There are ſeveral ſorts of Aſhes uſed in the improvement of land, ſuch as Coal-aſhes, Wood-aſhes, Turf-aſhes, Fern-aſhes, Furze and Heath-aſhes.—Aſhes of all ſorts of burnt vegetables, ſuch as burnt weeds, ſedge, ſtraw, ſtubble, bean-haulms, &c. alſo Pot-aſhes, and Soap-aſhes from the ſoap-boilers.

All theſe ſorts of Aſhes are of particular utility in the improvement of cold, wet, ſtubborn land, to warm, open, and looſen the mould, and augment its vegetable and prolific quality.

Coal-aſhes are particularly efficacious in the meliorating and fertilizing all cold, ſtiff, or

or clayey ſoils, in gardens or fields, and in graſs ground of the above quality; they have a great effect in preventing the rankneſs and coarſeneſs of the graſs peculiar to ſuch ſoils, by making it come finer, and rendering it more ſweet for cattle to feed on.

ASH-KEYS, the fruit, or ſeed-veſſel, of the Aſh-tree. See FRAXINUS.

ASPARAGUS, *Aſparagus*, falſely called Aſparragraſs.

The common Aſparagus is one of our choiceſt eſculents of the ſpring and beginning of ſummer, and highly merits culture in every garden.

But beſides the common Garden Aſparagus, the botaniſts preſent us with nine or ten more ſpecies in the ſame genera, under the title of Aſparagus, which are principally tender ſhrubby exotics of the green-houſe and ſtove; ſeveral of which are retained in our gardens, which we ſhall take notice of after the culture of the eſculent kind.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, ſix petals, forming a tube below, and ſpread at top. STAMINA, ſix ſhort filaments, and roundiſh antheræ. PISTILLUM, a trigonous germen, very ſhort ſtyle, and prominent ſtigma. PERICARPIUM, a globoſe berry, of three cells, each having two roundiſh ſeeds.

We ſhall firſt of all proceed in the culture of the common Aſparagus, and the following is the ſpecies.

ASPARAGUS *Officinalis.*

The *Officinal, or Common Aſparagus.*] Aſparagus, with an erect herbaceous ſtalk, three or four feet high, and very fine briſtly leaves.

This is a perennial fibrous-rooted plant, the roots being of many years duration, but the tops or ſtalks are annual, and the plants being raiſed from ſeed, they, after having acquired a period of three years growth, produce proper ſized Aſparagus, and of which, the ſame roots furniſh an annual ſupply for many years, continuing to riſe in perfection for ſix or eight weeks each ſummer; then the ſhoots run up to ſtalks, flower, and perfect ſeeds in autumn.

It is the young ſhoots, or ſtalks, of the plant that are uſed, which, when from about one, to four or five inches long above the ſurface of the ground, are in the greateſt perfection.

The natural ſeaſon of theſe plants for uſe is, from about the beginning of May, until the middle or latter end of June. For about the fourth week in April, or firſt in May, the roots begin to ſend up ſhoots or buds, and as often as theſe are gathered, new ones continue riſing in ſucceſſion from the ſame roots; but in order to preſerve the roots in vigour, it is adviſeable to leave off cutting the buds about the third or fourth week in June. The common rule is, to continue cutting about ſix or ſeven weeks, then permit the whole to run up to ſtalk.

But beſides the crop of natural Aſparagus in ſummer, it may alſo be obtained in perfection in winter, and early in ſpring, by the aid of hot-beds. See the *Method of forcing Aſparagus.*

*Propagation of the Plants.*

The propagation of Aſparagus is by ſeed only, which is ſold cheap enough at all the ſeed ſhops. It is to be ſown in February, or beginning of March, in a four-feet wide bed of rich earth, broad-caſt on the ſurface, and directly tread it in, and rake the ground.

In ſix weeks, or thereabouts, the plants will appear. Keep them clean from weeds all the ſummer, and in winter ſpread a little litter on the ground, to defend the crowns of the roots from froſt, and in ſpring following they will be fit to be tranſplanted, where they are finally to remain, as hereafter directed, which, in two or three years after, will produce Aſparagus fit to gather; for, obſerve, Aſparagus is always three years, at leaſt, from the time of ſowing the ſeed, till the plants obtain ſtrength enough to produce ſhoots of due ſize for the table; that is, one year in the ſeed bed, and two after being tranſplanted; but the ſame plantation will continue producing good Aſparagus ten or twelve years, nay, will even endure fifteen or twenty years; but at that age, the ſhoots will be ſmall, and the whole annual produce inconſiderable; a new plantation ſhould therefore be made once every eight, ten, or twelve years, as you ſhall judge neceſſary.

If you are deſirous to have a new plantation of Aſparagus, fit for uſe, as ſoon as poſſible, you may gain a year, by purchaſing ready raiſed year-old plants of the nurſery-men, or kitchen-gardners, at a ſhilling or eighteenpence per hundred.

But this is only meant for private uſe, as thoſe who raiſe great quantities for ſale, would find it very expenſive to purchaſe roots for large plantations, ſome of which, in the neighbourhood of London, are very extenſive, particularly about Deptford, where ſome of the gardeners have twenty acres of ground employed in Aſparagus.

Method

*Method of Planting.*

The time of year to make a plantation of theſe plants, is any time in March, in common light ground, and at lateſt, the firſt or ſecond week in April; but in cold very moiſt ſoils, from about the twentieth of March to the 15th of April, is the proper time to plant them in ſuch land.

With regard to ſoil and ſituation, the plants ſucceed tolerably in any common pliable ſoil of the kitchen-garden; but it is, however, eligible to allow them a ſpot of the very beſt and richeſt moderately light ground, in one of the open quarters, expoſed to the free air and full ſun; for this is of much importance. Dung muſt be added, ſix or eight inches thick at leaſt, but if ten or twelve the better. The ground is then to be trenched one or two ſpades deep, as you ſhall ſee neceſſary, burying the dung regularly in each trench, obſerving, if you trench but one ſpade deep, bury the dung in the bottom, but if you dig two ſpades, bury it betwixt the firſt and ſecond ſpit, about ten or twelve inches below the ſurface; and if the trenching is performed in winter, or any conſiderable time before the planting ſeaſon, it is proper to throw the ground in ridges, ſo level it down when that time arrives. See TRENCHING and RIDGING GROUNDS.

The neceſſary ſpace of ground to plant for private ſervice, is from about five, to fifteen rod, making the calculation according to the extent of the family.

The proper quantity of plants to a rod, excluſive of the alleys, is about 260.

Always chuſe one year old plants, not older, as thoſe of that age will eſtabliſh themſelves ſooner, and more effectually than older roots.

The plants, at the time of planting, conſiſt only of roots; they, at the proper time, are to be taken up from the ſeed-bed with a dung-fork, as entire as poſſible; and ſort out the ſtrongeſt for planting, which are not to be trimmed, only cutting off ſuch parts as are broken or bruiſed.

They are to be planted in rows a foot aſunder, and formed into beds, each bed to conſiſt of four rows, allowing three foot and half alleys betwixt bed and bed, and are to be planted in drills, or ſmall trenches, in the following manner. Begin at one end of the plat of ground, and ſtretch a line croſs-ways eighteen inches from the end; then with the ſpade held in an erect poſition, cut out a narrow trench, cloſe along the outſide of the line, ſix or eight inches deep, making the ſide next the line nearly upright. This done, get the roots, and place them againſt the upright ſide of the trench, ten or twelve inches diſtance, with the crowns two inches below the ſurface, ſpreading the fibres both ways, and draw a little earth up about each plant as you go on, juſt to fix them till the row is planted. One row being thus formed, move the line a foot farther, and caſt out another trench, the earth of which readily covers the plants of the firſt; place the roots as before directed, and ſo on to a third and fourth row, making the earth of each trench cover in the plants of that immediately before it; and when four lines are planted, one bed is formed. Then meaſure off three feet ſix inches for an alley, &c. and proceed to plant another bed of the ſame dimenſions; and after that, leaving another three-foot and half alley, plant a third bed, and in this manner proceed until your plantation is completed.

The beds and alleys may either be lined out now, or deferred till the winter dreſſing, obſerving, that of the three feet ſix inches directed for alleys, two feet only are to be allowed for that uſe, the other foot and half is to be added to the beds, which makes each bed four feet and half wide, i. e. nine inches on each ſide wider than the two outſide rows of plants; but at this time the alleys are only to be trodden out, taking out none of the earth, and ſo ſtand in the alleys and lightly rake the beds ſmooth.

But in making the above plantation, that if you have occaſion to make the moſt of every ſpot of ground, a thin crop of onions may be ſown the firſt year on the ſame plat as ſoon as the Aſparagus is planted; ſo tread in the ſeed, and rake the beds with a light and even hand.

The Aſparagus being planted, their culture is as follow. Their ſhoots will appear above ground the beginning of May not bigger than ſtraws, ſo muſt be permitted to run wholly to ſtalk. During ſummer they muſt be kept clean from weeds, by ſmall-hoeing them three or four times in the courſe of that ſeaſon; and if there is a crop of onions, thin them in the uſual way, cutting up any that grow immediately about the Aſparagus. In October, when the Aſparagus ſtalks decay, cut them down, clear off weeds, and dig the alleys two feet wide, (See *Winter Dreſſing*) burying the weeds therein, and ſpread ſome of the earth over the beds, which is all that is neceſſary

neceſſary to be done until March, at which time the beds ſhould be deeply hoed and raked ſmooth, permitting the ſhoots to run as in the firſt ſummer; and in October, cut down the decayed haulm as before, and land up the beds. In ſpring following, being the ſecond after planting, ſlightly fork-dig the beds, (ſee *Spring Dreſſing*) and rake them level, and in this ſpring the ſhoots will riſe of tolerable ſubſtance, when you may begin the firſt gathering. See *Winter Dreſſing*, *Spring Dreſſing*, *Manuring the Beds*, and *Gathering the Buds*.

*Winter Dreſſing, or Landing up the Beds.*

From about the middle of October, to the latter end of November, is the time to give the Aſparagus beds their Winter Dreſſing.

This dreſſing conſiſts in cutting down the decayed ſtalks of the plants annually at the above time, and clearing the beds from weeds, digging the alleys, and ſpreading ſome of the earth on the top of the beds, which is called landing up the beds.

It is done in the following manner.

The decayed ſtalks or haulm are to be cut down with a knife within an inch or two of the ground, then with a ſharp hoe cut up all weeds, at the ſame time drawing them off into the alleys to be buried. This done, proceed to line out the alleys, ſtretching the line along the edges of the beds about nine inches from each outer row of plants; the ſtumps of the ſtalks will be a guide; then with a ſpade chop the ground along by direction of the line, by which you form each bed four feet and half wide, and the alleys two feet. See the *Method of Planting*. The alleys are then to be dug one ſpade deep, and a good portion of the earth ſpread over each bed three or four inches thick; as you proceed in digging, the weeds drawn off the beds are from time to time to be trimmed into the bottom, and buried a due depth, obſerving to land the beds all a regular thickneſs, ſo as to make them about ſix or eight inches higher than the level of the alleys, forming the edge of each bed full and ſtraight.

The above work of landing the Aſparagus beds muſt be repeated every autumn.

It may by ſome be thought, that by an annual landing of the beds, they in ſeveral years will be conſiderably raiſed; but obſerve, that by the ſpring forking and raking, together with the repeated hoeings and clearing off weeds in ſummer, and at the time of landing up in autumn, a conſiderable part of the earth is annually drawn off again into the alleys.

After performing the winter dreſſing of theſe beds, a row or two of cabbage plants may be planted in each alley, as a place of ſhelter during winter, by which they will be forwarded for early ſpring coleworts; or a row of mazagan dwarf beans may be planted in October or November, in the warmeſt ſide of each alley, for an early crop. The market gardeners alſo often occupy the beds during winter, by planting a crop of cabbage lettuce hereon for ſpring ſervice, which being all gathered or tranſplanted elſewhere by the beginning of April, do not injure the Aſparagus.

*Of the Spring Dreſſing the Beds.*

The Spring Dreſſing of Aſparagus beds conſiſts in fork-digging the beds annually to a moderate depth, to looſen the ſoil, that the buds may freely advance and ſwell to their due ſize.

The time for performing this work is any time in March, but not to defer it later than the firſt or ſecond week in April, becauſe many of the buds will then be formed, and in forward ſeaſons, begin to advance in growth.

This work of looſening the beds is performed with a flat three-tyned fork.

Obſerve, however, that in the firſt ſpring dreſſing after planting, it is proper to looſen the ſurface only with a hoe, two or three inches deep, and ſo rake the beds ſmooth.

But in reſpect to the general ſpring dreſſing, it is to be annually performed by fork-digging, to all ſuch beds that have been planted more than one year, which ſhould be ſlightly dug four or five inches deep with the Aſparagus-fork, being careful to looſen all the earth as deep as the ſurface of the roots, having regard, however, not to wound the crowns of them; and after forking, let all the beds be neatly raked, to break clods, clear off ſtones, and to form a level and ſmooth ſurface, finiſhing each bed with a gentle rounding.

*Of Dunging, or Manuring the Beds.*

Theſe beds ſhould be enriched with an augment of good rotten dung once every two years, the benefit of which will be evident in the quantity, as well as the ſize and quality of the produce.

The time to apply this manure, is at the time of winter dreſſing, or landing up the beds.

The dung for this purpoſe ſhould be perfectly well rotted; none better than the dung of old cucumber and melon beds, or any other

of

of ſimilar quality, which ſhould be applied when the ſtalks and weeds are cleared off, the dung is to be ſpread three inches thick over the ſurface of each bed, and a double portion in the alleys; the beds are then to be ſlightly forked to bury the dung; after this dig the alleys in the uſual way, and ſpread a portion of the earth evenly over the beds.

The winter rains will waſh the enriching quality of the above manure into the beds, and the roots will reap the benefit thereof in ſpring.

*Of Gathering the Produce.*

We formerly obſerved, that Aſparagus, from the time of ſowing the ſeed, till the plants produce buds large enough for uſe, is commonly three or four years; that is, one in the ſeed-bed, and two or three after being tranſplanted; they, however, ſometimes, in very rich ground, yield tolerably large buds the ſecond year, but of which I ſhould adviſe to cut only here and there one of the largeſt that happen to appear the firſt week or fortnight; afterwards permit the whole to run to ſtalk; but in the third year you may perform a more general gathering, and continue it a month or five weeks; and in the fourth year, the general produce will riſe in its utmoſt perfection: you may then, and every ſucceeding year, gather all the buds ariſing from every plant during the ſeaſon of Aſparagus.

The proper ſize of the buds for uſe is, when they are from about one to four or five inches high above the ſurface of the earth, while the heads remain compact and plump.

The principal ſeaſon of cutting them, is from the latter end of April, or beginning of May, according to the forwardneſs of the ſeaſon, until the middle or latter end of June.

They might, however, be obtained a month or two longer in the ſeaſon, by continuing to cut all the buds according as they attain proper ſize; but this would be a very wrong practice, as the roots would thereby continue ſending up a freſh ſupply, till they in a manner exhauſted their vegetable fund, as would be apparent by the inconſiderableneſs of the future year's crop, and ſhort duration of the plants.

The gatherings therefore ſhould be terminated about, or ſoon after the 20th of June, eſpecially, as by that time there will be plenty of young peas, to ſubſtitute as a diſh at table in lieu of the Aſparagus.

If late Aſparagus is however wanted, ſome beds ſhould be ſet apart for that purpoſe, excluſive of the main crops.

For the purpoſe of cuttting the Aſparagus for uſe, it is neceſſary to be furniſhed with a long ſtrait narrow-pointed kniſe, the blade ſix or eight inches long, teethed on the edge like a ſaw; and in cutting the Aſparagus, ſlip the kniſe down cloſe to each ſeperate bud, and cut them off ſlanting three or four inches within the ground, being careful not to injure any of the younger buds riſing in ſucceſſion, there being generally ſeveral from the ſame root, advancing in different ſtages of growth.

The gardeners who ſupply the London markets with Aſparagus, ſort it into three ſizes, a large, middling, and ſmall ſort; the former they call ware, the next middlings, and the latter ſprew; they ſell it wholeſale by the baſket, three, four, or five hundred buds in each, according to their ſize, and thoſe that retail it, bind it in bundles, from one to three hundred in each bundle.

In preparing Aſparagus for the table, the cook ſhould ſlightly ſcrape each ſhoot, to diveſt them of the ſmall ſcaly parts annexed to their ſides, tye them in ſmall bunches, the heads all one way, then cut the white ends even; they are then ready for boiling, which is effected in fifteen minutes.

*Forcing or raiſing early Aſparagus.*

As many families are anxious to have Aſparagus in winter, and early in ſpring, I ſhall next proceed to the method for obtaining it alſo in theſe ſeaſons.

This is effected by means of planting the roots in ſubſtantial hot beds, covered with frames and glaſſes, as hereafter directed.

This work is by gardeners called forcing Aſparagus.

As the practical method of forcing Aſparagus has not been digeſted by former authors on gardening, I propoſe to handle this article at ſome length, according to real practice, for the benefit of my brother-gardeners, who have not had the opportunity of ſeeing the true practical part; and as the London kitchen-gardeners, having great experience, by forcing vaſt quantities annually, it is generally allowed they excel in the production of winter Aſparagus, I ſhall exhibit the whole culture according to their method.

Previous to this work it muſt be obſerved, that when intended to have a conſtant ſucceſſion of Aſparagus during winter and ſpring, a new hot-bed muſt be made, and planted with freſh plants every three or four weeks, for theſe roots, when forced in hot-beds, do not continue to yield any tolerable produce longer

longer than that period of time, when they will in a manner be quite exhauſted, and are not fit for that nor any other purpoſe afterwards: therefore, for this purpoſe of forcing, a freſh quantity of plants muſt be in readineſs for every new hot bed: theſe are raiſed in the natural ground to a proper age; they muſt be three or four years old; that is, the plants are raiſed from ſeed, as directed for the natural-ground Aſparagus, and when they are one year old, tranſplant them in beds of rich earth, as directed alſo for the natural plantation, in rows a foot aſunder, but need not be more than nine inches diſtance in each row, forming them in beds of ſix rows in each, with only two feet alleys, juſt to go in to clean off weeds, &c. for the beds need not be landed up in winter, as in the natural Aſparagus; and when the plants have had two ſummers growth, they, in good ground, will be fit for forcing, though they will be in greater perfection, if permitted to ſtand three years. During the time they remain in the natural ground, no buds ſhould be gathered, at leaſt very few, but permit the whole to run to ſtalk each ſummer.

It muſt next be obſerved, that when intended to force Aſparagus annually, ſome ſeed muſt be ſown every ſpring, and a due quantity of plants tranſplanted as before directed, ſo as to have three different pieces of ground always employed at the ſame time with Aſparagus plants for the above purpoſe; that is, one piece with ſeedlings in the ſeed-bed, the other two with tranſplanted plants, one to be a year's growth before the other; by which practice, after the three firſt years, you will obtain an annual ſucceſſion of plants fit for a forcing.

But as ſome perſons may be impatient to wait the raiſing the plants, or may be anxious to have a ſupply till their own are ready, in which caſes, they may be furniſhed with them at moſt of the kitchen-gardeners in the neighbourhood of great towns, particularly that of London, where they commonly ſell them by meaſurement of the ground they grow upon, generally from ſix to ten ſhillings per rod, according to the age, ſize of the plants, and fullneſs of the crop.

The neceſſary quantity of plants for hot-beds is conſiderable, ſince about as many as grow upon three rods of ground is requiſite for a bed intended for a common three-light garden-frame. The common allowance of the London gardeners is about one rod to a light; for the plants are to be placed as cloſe as they can poſſibly ſtand to one another, to the amount of five, ſix, or ſeven hundred, or more, according to their ſize, in a three-light box, otherwiſe a bed would not afford a ſufficient ſupply, adequate to the expence and trouble neceſſary in the culture of theſe plants in hot-beds; for, from a bed of the above dimenſions, we commonly expect about three hundred large buds, or ware, beſides ſprew, weekly, and in the whole about eight or nine hundred good Aſparagus, and near as many ſmall ones in three weeks, in which period of time the roots will have exhauſted their ſtrength, and can produce very little more.

Therefore, in raiſing or procuring plants for the above purpoſe, the quantity muſt be proportioned to the number of lights you intend working, and the ſucceſſion of Aſparagus required, which may be readily calculated according to the foregoing obſervations.

The ſeaſon to begin the above work of forcing, is according to the time the Aſparagus is required for uſe; as, for inſtance, if you would have Aſparagus at Chriſtmas, it is proper to make the hot-bed in the firſt or ſecond week in November, and ſo on in proportion to any other time of the winter or ſpring it is deſired to have Aſparagus fit to gather. The rule is this: if a conſtant ſucceſſion is required from about Chriſtmas till the time of the natural Aſparagus come in, a new hot-bed ſhould be made every three weeks or a month, as already obſerved, from the beginning of November until that of March; but ſome of the London gardeners begin about the latter end of September, in order to obtain Aſparagus againſt Lord Mayor's day, which happens the ſecond week in November.

Previous to making and planting the hot-bed, obſerve alſo the following particulars.

As to the hot-beds for this purpoſe, the proper materials are, a ſufficient quantity of horſe or ſtable dung, freſh, and full of heat, wherewith to make the hot-bed for one or more three-light frames, two feet and half, or a yard high; alſo ſome to lime it when the heat declines, a quantity of good kitchen-garden earth, and one or more three-light garden-frames to place over the bed, and ſome large garden-mats, to cover occaſionally on nights and bad weather.

The dung for making theſe beds is to be previouſly prepared, as directed under the article HOT-BEDS.

The ſituation for the hot-beds ſhould be where the ground is light, rich, and dry, for

the convenience of having plenty of good light earth at hand for earthing the bed, banking up the outſide plants, and moulding them at top, &c.

The expoſure ſhould be open to the full ſun, and defended from the northerly winds.

It is elegible to make the bed in a trench four or five feet wide and one deep, ſo that the earth dug out in forming the cavity, ſerves in part to earth the bed and plants as above.

As to the general dimenſions of the bed; it is made a foot wider and longer than the frames intended to cover it, that is, ſix inches on each ſide and end, whereon to bank up earth againſt the outſide roots, &c. and muſt be two feet and half, or a yard high, earthed at top ſix inches thick for the reception of the plants, which are placed entirely upon the top of the earth before the frame is put on, keeping them within the compaſs thereof, upright, and as cloſe as they can ſtand, as hereafter directed; and as there being a clear ſpace of ſix inches on each outſide and end, as above hinted, is to receive a wall or bank of earth againſt the outſide roots, and for the ſupport of the frame, the latter of which, on account of the firſt violent heat, is not put on till two or three weeks after planting the roots; theſe, as ſoon as planted and banked up on the outſides, are earthed an inch deep, which is encreaſed to five or ſix, when the buds appear through the firſt earthing, at which time, as the heat of the bed will be moderate, the frame and glaſſes are placed thereon. See the *General Culture*.

*Method of making the Bed, planting the Roots, and Culture.*

In the ſituation and expoſure above deſcribed, mark out a trench for the hot-bed, twelve or fourteen inches wider than the intended frames, and of a proportionable length, whether for one, two, or more, and dig out the cavity one ſpade deep, then wheel in the dung, and with which form the bed the full width and length of the trench, obſerving, if only for a ſingle three-light frame, make the bed a yard high, but if for two or more ſuch frames in one range, two feet and half depth of dung is ſufficient, working the whole upright and firm in the uſual way. See HOT-BEDS.

When the bed is thus formed, let it be directly earthed at top for the reception of the plants, with finely broken earth ſix inches thick, to the full width and length of the bed, and rake the ſurface level and ſmooth; this done, immediately proceed to place the roots, for no time muſt be loſt in Aſparagus hot-beds in waiting for the temperature of the heat. Previous to planting the roots, mark out on the ſurface of the bed the exact width and length of the frames, ſo as to have a clear ſpace on each outſide of ſix inches width, to receive the banking of earth againſt the outſide roots, &c. as before-mentioned; then begin at one end, and raiſe a ſmall ridge of earth croſsways upon the ſurface, about ſix inches high, againſt which to lay the firſt row of roots; then having the roots, which are not to be trimmed, lay the firſt courſe cloſe againſt the above ridge, and intirely upon the ſurface of the bed, with the crowns upright, and as cloſe to one another as you can poſſibly place them, and when one courſe or row is thus placed, lay another againſt theſe in the ſame manner, and ſo proceed, laying them one againſt another as cloſe together every way as you can poſſibly crowd them from one end of the bed to the other, without laying any earth between or about the fibres, for theſe will ſoon ſtrike down into the earth of the bed, being careful to place all the crowns of ſuch an equal height, that the whole may form, as it were, a level ſurface, keeping the whole rather within the meaſure of the frame, for they will unavoidably ſwell out a little on each ſide, obſerving, if more frames than one are intended for the ſame bed, then at the termination of the length of each frame, raiſe a croſs ridge of earth, as at firſt, about ſix inches in height; ſo proceed laying the plants, as before, and when all the roots are thus placed the whole length of the bed, directly bank up ſome earth on each ſide and end, as above hinted, againſt the outſide roots, raiſing it an inch higher than the crowns of them, then cover the crowns all over evenly with finely-broken light earth an inch deep, which finiſhes the work for the preſent until the buds appear, which ſee, for the roots muſt not till then be earthed deeper, nor the frame placed upon the bed, till the violent heat has ſubſided, becauſe it would confine the burning ſteam, and occaſion the bed to heat too vehemently, to the deſtruction of the plants.

In making the above beds, many of the London gardeners, to ſave dung, inſtead of making the beds a foot wider than the frames, as above directed, make them only the exact width of the frame; ſo to ſecure the outſide roots, and for the ſupport of the frame, raiſe a bank of earth quite from the ground,

ground, ſix inches broad, drawing it in gradually to the top, banking it cloſe againſt the ſides of the bed, and that of the outſide roots, raiſing it an inch higher than the crowns of them, ſo earthing them all over the top an inch deep, as before obſerved; which method of banking quite from the ground, is very effectual in preſerving the temperature of the bed, by defending the dung from driving rains, ſnow, and piercing winds.

As ſoon as the beds are made and planted in either of the above methods, then, in order to judge of the temperature of the heat, it is proper to thruſt ſome ſharp-pointed ſticks, two feet long, down betwixt the roots into the dung of the bed, and by drawing theſe up daily, and feeling the lower end, you will be able to judge of the degree of heat, whether too violent or weak, which is to be regulated accordingly, as hereafter directed.

The beds being made and planted, the roots will ſoon after ſend forth freſh fibres into the earth, and even, in time, into the very dung, and the buds of the Aſparagus will begin to appear in about three weeks; but till that period, as the heat will be very ſtrong, the bed is to remain unframed and uncovered, except being occaſionally defended at top with long litter or garden mats, from violent rains, ſnow, and ſevere froſty weather, obſerving, however, that until the buds appear, moderate rains, froſts, &c. can do no damage; therefore uſe only ſlight and occaſional covering, as above, juſt to preſerve the crowns of the plants until the heat of the bed is become quite moderate, for at this period too much covering would encreaſe the heat to a violent degree, and ſcorch the roots, which in ſtrong beds we muſt, at any rate, be particularly watchful to guard againſt; the temperature of heat muſt therefore be every day examined by the trying ſticks, and if it is found ſo vehement, that you judge the roots are in danger of ſcorching, the remedy is, to bore with a large rake-handle, &c. the ſides of the bed, quite through in ſeveral places, both in the dung, and betwixt the top of the dung and the earth, that the rank ſteam and burning quality may evaporate at the holes; at the ſame time the free air will have acceſs, and in two or three days the bed will be reduced to a moderate temperature.

When the Aſparagus begins to appear, they are then to have their final earthing of four or five inches depth of more mould all over the crowns of the roots, and the frame and glaſſes to be put on. Obſerve as follow.

At this period, i. e. that of the firſt appearance of the buds, prepare ſome light, rich, finely-broken earth, ſufficient to mould them the above depth; at the ſame time, in order to ſecure the outſides of the ſaid final earthing, it is proper to form a ſort of border, or empalement, round the top of the edges of the bed, four or five inches high, which is done either with a thick ſtraw-band, or by raiſing the outſide banking an additional four or five inches, either of which, as juſt obſerved, is neceſſary not only to ſecure the ſides and ends of the earth, but alſo to ſupport the frame a due height, the bottom of which ſhould ſtand nearly as high as the ſurface of the final covering of earth, ſo as there may be full ſcope between the earth and the glaſſes for the buds to ſhoot. But in reſpect to the above empalement round the top of the bed, that inſtead of forming it by banking higher with earth, it is more cuſtomary to fix a wreath of ſtraw-bands round the top of the firſt banking, to ſerve that purpoſe; this the London gardeners call wreathing the bed. It is done thus: when the buds firſt appear, make a large ſtraw-band or rope, four or five inches thick, and long enough to go round the bed; then upon the top of the banking, exactly in the place where the frame is to ſtand, place this band round ſingly in a neat and regular manner, faſtening it with pegs ſtuck through the ſides of it into the earth, and when this is fixed, directly earth the buds as high as the ſaid wreath, or about four or five inches deep, as above noticed, ſo as there may be now in the whole, about five or ſix inches depth of earth all over the crowns of the plants; then if the heat of the bed is become of a moderate temperature, it is proper to put on the frame, reſting it upon the top of the above wreath or ſtraw-band; or in default of this, ſet it immediately on the top of the banking, having been previouſly raiſed as above; after this, if you are anxious to have long buds, as is the caſe with the market gardeners, you may lay an inch depth of more earth, ſo as to make the whole full ſix inches thick.

The bed being now finally earthed and framed, and the heat is become moderate, the glaſſes or lights are to be kept conſtantly upon the frame, which on nights ſhou'd be covered with mats, or dry long litter, but muſt be uncovered every day, except in uncommonly ſevere weather, for it is of importance to admit as much light and ſun as poſſible, to promote a green colour in the tops of the buds;

and as to the admiſſion of freſh air, if the heat is moderate, the glaſſes need only be ſhoved a little open in fine days, eſpecially if you require the plants to be drawn up quick; but by admitting a larger portion of air, the buds riſe ſlower, and will acquire a larger ſize and greener colour, on which conſideration ſome, in the ſpring-made beds, take the glaſſes entirely off a few hours in fine mild dry days, particularly when the heat is conſiderable at the firſt appearance of the buds after the bed is framed.

At this time alſo, examine the temperature of heat in the bed. When it has been made about three weeks, if it is but a ſmall bed, only for one or two three-light frames, the heat will begin to decline conſiderably, which ſhould be renewed by a lining of hot dung applied to the ſides: do not omit this, particularly when the buds begin to appear through the laſt covering of earth, if you ſhould ſee occaſion, though beds of more conſiderable length ſeldom require lining till after the firſt breaking or gathering of the buds; then adding a good lining, it will maintain the bed in due temperature fifteen or eighteen days longer, which is as long as the roots continue yielding any tolerable produce. See LINING BEDS.

In about five or ſix weeks after the bed is made and planted, we may expect Aſparagus fit to gather; when the buds are from two to four or five inches high above the earth, they are of the proper ſize.

The method of gathering them in hot-beds is, by breaking the buds off near the root, and is done by thruſting the finger and thumb into the earth, and by a gentle twiſt the buds will readily break. For the ſupply of a family, the buds may be gathered every other day, or oftener, if neceſſary; but for market, the gardeners ſeldom make more than three principal gatherings, or breakings, from the ſame bed, that is, one every week for three weeks, and the ſecond breaking is generally the beſt, which in Covent-garden market is ſold from ten to thirty ſhillings a baſket, each baſket conſiſting of about 300 buds, and which of thoſe they call ware, are often very large and fine for the ſeaſon. But the Rev. Mr. Hanbury, in his Body of Gardening, ſays, the forced Aſparagus brought to Covent-garden market, is ſcarcely bigger than wheat-ſtraws, which he attributes to the ignorance of the gardeners, in which, however, as well as in the true culture of forcing Aſparagus, that gentleman is greatly miſtaken; for the London gardeners having conſiderable practice in that article, many of whom force upwards of a hundred lights annually, that they generally excel moſt others in the culture of forced Aſparagus, and ſupply the markets therewith in great perfection, eſpecially from about Chriſtmas till the arrival of the natural crops. Indeed, in the beſt-managed beds, there will, beſides the main crop of large buds or ware, be many of middling growth, and many ſmall buds or ſprew; ſo the gardeners ſort them accordingly for market, into ware, middlings, and ſprew, the latter of which is ſometimes not much thicker than large ſtraws.

*Of the* ASPARAGUS FRUTICOSA, *or* Shrubby Aſparagus, *including alſo the Dragon-tree, one of the Palms, but now ranged by Linnæus as a ſpecies of Aſparagus.*

Beſides the eſculent ſpecies of Aſparagus already treated of, there are ſeveral other ſpecies in the ſame genus, moſtly of ſhrubby growth, exotics of the green-houſe and ſtove.

The ſpecies of moſt eſteem are,

[1]ASPARAGUS *Albus.*

*White Prickly Portugal Aſparagus.*] Aſparagus, with ſhrubby very white ſtalks, and flexible branches, growing four feet high, ornamented with ſhort, fine, chaffy, deciduous leaves, in cluſters from one point, and ſharp ſpines under each tuft of leaves.

[2]ASPARAGUS *Declinatus.*

*Declinated Briſtly-leaved African Aſparagus.*] Aſparagus, with ſeveral ſhrubby, erect, ſmooth ſtalks; infirm declinated branches, cloſely covered with briſtly evergreen leaves.

[3]ASPARAGUS *Acutifolius.*

*Acute-leaved Portugal Aſparagus*] Aſparagus, with ſhrubby, crooked, ſmooth, whitiſh ſtalks, growing about four feet high; ſmall, rigid, prickly-pointed, evergreen leaves, in cluſters from the ſame point.

[4]ASPARAGUS *Retrofractus.*

*Retrofracted Great Prickly Larch-leaved Aſparagus.*] Aſparagus, with ſhrubby very crooked ſtalks, riſing eight or nine feet high, emitting infirm reflexed branches, adorned with long, fine, narrow, evergreen leaves, in cluſters from one point, and a ſingle ſharp thorn advancing under each tuft of leaves.

Theſe four ſpecies flower here annually, which, like the common Aſparagus, are very inconſiderable, and are ſeldom ſucceeded by ſeeds in England.

*Their Culture, &c.*

The above four ſpecies are exotics of the green-houſe, ſo muſt always be kept in pots, and managed

managed as the other plants of that department. See GREEN-HOUSE PLANTS.

Their propagation may be readily effected by ſlipping the roots in March or April.

If ſeed can be procured, they may alſo be raiſed abundantly that way, by ſowing it in pots in March or April, and plunge them in a hot-bed, juſt to bring up the plants, which in Auguſt will be large enough for tranſplanting into ſeparate pots.

[5]ASPARAGUS *Draco.*

*The Draco Arbor, or Dragon-tree, from the Cape Verd Iſlands.*] Aſparagus, with a large ſingle or unbranching trunk, riſing twelve or fourteen feet high, the top crowned with a circular cluſter of ſword ſhaped, pointed leaves, a yard or more in length, placed ſingly, without foot-ſtalks round the ſtem, and hang down on every ſide in a ſingular manner, but rarely flowers in England.

From this plant flows, by inciſion, a red gummy juice, of medical property, commonly called Dragon's Blood.

This ſpecies is an exotic of the hot-houſe, and retained in many of our gardens, as a plant of ſingular growth and appearance, bearing reſemblance in growth and leaves to the *Yucca*, or Adam's Needle.

It is of the Palm kind, moſt of which are of ſingular growth. See PALMÆ, &c.

The propagation of this plant is by ſeed, which is procured from abroad, ſown in pots, and plunged in bark hot-beds; by which aſſiſtance the plants will ſoon come up, giving occaſional waterings, and when three inches high, tranſplant them into ſeparate pots, continuing them always in the ſtove, except in the months of July and Auguſt, when they may be expoſed in the open air.

During ſummer they muſt be frequently watered, which muſt alſo be performed in winter with moderation.

ASPERIFOLIÆ Plantæ, Rough leaved Plants, and in antient botany the name of a claſs, conſiſting of plants whoſe leaves are rough to the touch, and have four naked ſeeds; of which are *Anchuſa*, or Bugloſs; *Borrago* Borage; *Cynogloſſum*, Hound's-tongue; *Symphytum*, Comfrey, &c. the leaves of all of which are ſimple, alternate, and attached to the ſtems and branches, without any foot-ſtalk.

ASPHODELUS, Aſphodel, or King's-Spear, ſo called from the reſemblance of its ſpiked flowery ſtalk to a royal ſcepter.

The plants of this genus are herbaceous flowery perennials, with fleſhy fibrous roots, producing annual ſtalks two or three feet high terminated by long ſpikes of many liliaceous flowers of ornamental appearance.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA conſiſts of one petal, cut into ſix ſpear-ſhaped ſpreading ſegments, and at bottom a globular nectarium of ſix valves. STAMINA, ſix ſubulate arched filaments, alternately long and ſhort, attached to the valves of the nectarium, and oblong incumbent antheræ. PISTILLUM, a globular germen within the nectarium, awl-ſhaped ſtyle, and truncated ſtigma. PERICARPIUM, a globular fleſhy capſule of three cells, filled with triangular ſeeds.

There are but three diſtinct ſpecies, all of which have fleſhy fibrous roots.

The ſpecies are,

[1]ASPHODELUS *Luteus.*

*Common Yellow Aſphodel.*] Aſphodelus with an upright, unbranching, large, round, leafy ſtalk, growing near three feet high, adorned half-way with numerous long, triangular, hollow, ſharp-pointed leaves, and many ſtarry yellow flowers, forming a long erect ſpike from the middle of the ſtalk upward.

[2]ASPHODELUS *Alba Ramoſus.*

*Branching Great White Aſphodel.*] Aſphodelus with branching unleaved ſtalks a yard high; ſword-ſhaped, long, hollow, flexible leaves, in large tufts directly from the root, and in the midſt of them the ſtalk, emitting many ſide branches, adorned upward with long ſpikes of many large, ſtarry, white flowers, having a purple line running down each ſegment.

[3]*Variety.*] ASPHODELUS *Alba non Ramoſus.*

*Unbranching White Aſphodel.*] Aſphodelus, with ſimple or unbranching leafleſs ſtalks a yard high; ſword-ſhaped, very narrow, flexible leaves from the root, and amongſt them iſſue the ſtalk, upright, without branches and leaves, terminated by a very long ſpike of many ſtarry ſnow-white flowers.

[4]ASPHODELUS *Fiſtuloſus.*

*Fiſtular*, or *Hollow-leaved Minor White Aſphodel*] Aſphodelus with upright, branching, leafleſs ſtalks, eighteen inches high; awl-ſhaped, ſtriated, fiſtular leaves, hollow like a pipe, riſing in a large tuft from the root, in the midſt of which iſſue the ſtalks, dividing upward into a few branches, adorned at top with ſtarry white flowers ſtriped with purple.

*Variety.*] Fiſtular-leaved Annual White Aſphodel.

The roots of all theſe Aſphodels conſiſt of many thick fleſhy fibres, connected at top into one common head; to thoſe of the ſecond and third,

third, hang many oblong thick tubers, all of which roots are of perennial growth.

The leaves and ſtalks riſe annually from the roots in ſpring, and periſh in autumn, after they have flowered and perfected ſeeds.

The flowers are numerous on each ſtalk, ſurrounding them from the middle upward, forming a ſpike of innumerable buds, opening in ſucceſſive order; each ſeparate flower conſiſts of one leaf, or petal, deeply cut into ſix ſegments, ſo as to appear ſo many different petals, opening in June, continuing in ſucceſſive order a month or ſix weeks, and are ſucceeded by plenty of ripe ſeeds in autumn.

*Culture, Propagation, &c.*

All theſe three ſpecies demand attention as plants of ornament, as during their bloom they make a noble appearance, and may be employed as choice furniture for the embelliſhment of the principal compartments of the pleaſure ground.

They ſucceed in any common ſoil and ſituation, and are of eaſy culture.

Their propagation is eaſily accompliſhed by ſeed, and by parting their roots. Sow the ſeed in autumn or ſpring in a bed of light earth, and in April or May the plants will appear, which in autumn or ſpring after tranſplant into nurſery-beds, ſix inches diſtance, where they will flower the following ſummer, and in autumn after remove them to the open borders.

By dividing, or ſlipping the roots, they may be encreaſed plentifully, which may be performed in autumn or ſpring. Plant the ſlips directly where they are to remain, and they will all flower the following ſummer.

ASTER, Starwort, ſo called from the figure of its radiated flower.

The Aſters are moſtly herbaceous, fibrous-rooted, flowery plants; ſome are annual, but the greater part are hardy perennials, producing annual ſtalks of different ſtatures, from one to five feet in height, the whole adorned with ſimple leaves, and terminated at top by compound radiated flowers. See RADIUS. There are alſo ſome ſhrubby plants of the green-houſe.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a ſcaly, imbricated, general cup, containing numerous florets. COROLLA is compound and radiated, many funnel-ſhaped hermaphrodite florets form the diſk, and flat female florets, three-parted at the end compoſe the border, or radius. STAMINA, five filaments, and cylindric antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and bifid ſtigma; and in the female florets, the ſtyle is crowned by two ſtigma, which are oblong and revolute. PERICARPIUM, none, and a ſingle downy ſeed ſucceeds each floret.

There are upwards of thirty ſpecies, ſeveral of which produce large and elegant flowers; and thoſe of an annual ſpecies, called *China After*, are remarkably grand and beautiful; ſome of the perennials are alſo very ſpacious and ſhowey, all of which adorn our gardens in autumn.

Firſt of the annual ſort, which is,

1 ASTER *Chinenſis.*

*The China After, or Annual Starwort, from China, or Queen Marguerette.*] After with only one ſtalk from the root, dividing into many ſpreading branches, growing about two feet high, ornamented with oval, angular, indented foot-ſtalked leaves, and every branch crowned by one large beautiful radiated flower, appearing in Auguſt, September, and October.

*Varieties of this are.*] China After, with ſingle white flowers—ſingle blue flowers—ſingle purple flowers—ſingle red flowers,—with double white flowers—double blue flowers—double purple flowers—double red flowers,—and with variegated blue-and-white flowers; all of which varieties, in their ſingle ſtate, conſiſt of a broad yellow diſk, encompaſſed by a ſeries of flat ſpreading florets, forming the circumference, or radius; but the double flowers have many ſeries of ſuch florets continued to the very centre.

All the varieties are but of one ſummer's duration, riſing from ſeed in ſpring, flower and perfect ſeed plentifully in autumn, and periſh root and branch in November; ſo a freſh ſupply muſt be raiſed annually.

*Their Culture.*

This ſpecies *After Chinenſis* is one of the moſt elegant and ſhowey annuals that ornament our gardens, all the varieties of which are curious furniture for the embelliſhment of the common borders; and as they are of eaſy culture, may be obtained plentifully in every garden.

Their propagation is by ſeed ſown annually in March, April, or beginning of May, in a hot-bed, or warm border, from which the plants are to be tranſplanted into the borders.

Be careful to procure ſeed of the different varieties, as white, blue, red, &c.

The

The ſeed is commonly ſown in a moderate hot-bed; it will, however, grow freely in a warm border, if ſown about the middle, or latter end of April, or beginning of May, but by the aid of a hot-bed, juſt to raiſe the plants, it will forward them ſooner, by almoſt a month, to a ſtate of flowering. Sow the ſeed either on the ſurface, or in ſmall drills drawn with the fingers, and cover it a quarter of an inch deep with fine earth, and when the plants appear, inure them betimes to the open air, previous to their being tranſplanted, and give frequent waterings. See ANNUAL PLANTS.

In May or June, when the plants are three inches high, tranſplant them into the natural ground in the places where they are to remain to flower, taking opportunity of ſhowery weather, and let them be properly diſpoſed in every border, and other compartments contiguous to the principal walks, lawns, &c. a yard, at leaſt, diſtance from one another, where they will make a grand ſhow in Auguſt, September, and October, eſpecially if there are varieties of different colours.

For ſome other particulars in their culture, ſee ANNUAL PLANTS.

If any are wanted for pots to adorn court-yards, &c. ſome of the fineſt double ſorts of different colours ſhould be ſelected as ſoon as they ſhew bloom; ſo take them up with large balls about their roots, and plant one in each pot, giving water plentifully.

To ſave ſeed of this ſpecies, it ſhould be gathered only from the perfect double flowers of the moſt lively colours, which will be ripe the end of September and October, taking opportunity of dry days, to cut off the heads as they ripen.

The hardy perennial ſorts are,

[1]ASTER *Tradeſcanti.*

*Tradeſcant's Virginia Starwort, erroneouſly called Michaelmas Daiſy.*] After with numerous, erect, branching ſtalks, about four feet high, adorned with oblong acute-pointed leaves, broad at the baſe, which half embrace the ſtalk, and all the ſtalks and branches terminated by pale blueiſh flowers, appearing in October.

[2]ASTER *Amellus.*

*Amellus, or Italian Starwort.*] After with numerous, upright, firm ſtalks two feet high, ornamented below with ſpear-ſhaped, blunt, three-veined, rough entire leaves, and the tops crowned by corymbus cluſters of large flowers, on naked foot-ſtalks, having a golden centre, and bright blue radius, appearing in October and November.

[3]ASTER *Alpinus.*

*Alpine Dwarf Starwort.*] After, with upright unbranching ſtalks about a foot high, garniſhed with ſpear-ſhaped hairy leaves, the radical ones blunt, and each ſtalk ſurmounted by one large blue flower, appearing in June and July.

[4]ASTER *Novæ Angliæ.*

*New-England Starwort.*] After with many erect hairy ſtalks about five feet high, decorated with ſpear-ſhaped entire leaves, growing alternate; their baſe half ſurround the ſtalk, and all the ſtalks terminated by panicles of large violet-purple flowers, appearing in Auguſt and September.

[5]ASTER *Altiſſimus.*

*Talleſt Philadelphia Purple Aſter.*] After with upright, unbranched, hairy ſtalks eight or ten feet high; oblong pointed hairy leaves; their baſe half embrace the ſtalks, and each ſtalk terminated generally by three large reddiſh-purple flowers, appearing in November.

[6]ASTER *Grandiflorus.*

*Great Blue Pyramidal Aſter, or Cateſby's Virginia Starwort.*] After with ſtalks a yard high, emitting many ſide-branches, adorned with ſpear-ſhaped, reflexed, rough leaves, and every branch crowned by one large blue flower, having a rough calix, appearing in the end of October and November.

[7]ASTER *Puniceus.*

*Purple-ſtalked American Aſter.*] After with upright purple ſtalks three feet high, garniſhed with ſpear-ſhaped, ſawed, rough leaves; their baſe half embrace the ſtalk, and each ſtalk terminated by a corymbus cluſter of pale blue flowers, growing ſingly on alternate foot-ſtalks, appearing the end of September and October.

[8]ASTER *Linifolius.*

*Flax-leaved Aſter.*] After with ſtrong erect ſtalks about a yard high, ſending forth many ſide-branches, forming a corymbus, narrow, acute-pointed, entire, alternate leaves; their baſe half embrace the ſtalk, and every branch terminated by one blue flower, appearing in Auguſt and September.

[9]ASTER *Undulatus.*

*Waved-leaved Aſter.*] After with branching ſtalks about a yard high, heart-ſhaped waved leaves, downy underneath; their baſe embrace the ſtalks, and each branch terminated by an aſcending ſpike of whitiſh-blue flowers, appearing in September.

[10]ASTER *Ericoides.*

*Heath-like Buſhy Starwort.*] After with ſlender very branchy buſhy ſtalks about three feet high,

high, closely garnished with very narrow entire leaves, and each branch terminated by a small whitish flower, having leafy foot-stalks, appearing in October.

[11]ASTER *Cordifolia.*

*Cordated Broad-leaved After.*] After with slender stalks about two feet high; heart-shaped, pointed, sharply serrated, foot stalked leaves, and the upper parts of the stalk dividing into many branches, terminated by pannicles of white flowers; in September.

[12]ASTER *Glaber.*

*Smooth Peach-leaved After.*] After with branching stalks about five feet high; oblong, spear-shaped, acute, serrated, smooth leaves, and all the branches dividing at top into several spreading foot-stalks, each ending in a large pale blue flower, appearing in October.

[13]ASTER *Rigidus.*

*Stiff-leaved White Virginia After.*] After with branchy stalks about three feet high, very narrow alternate leaves, and each stalk and branch terminated by one white flower, appearing in November.

[14]ASTER *Tenuifolius.*

*Narrow Belvedere-leaved American After.*] After with branching stalks four or five feet high, very narrow entire leaves, and all the branches ending in long spikes of whitish-blue flowers, appearing the end of October.

[15]ASTER *Concolor.*

*Single-stalked Virginia Starwort.*] After with single or unbranched stalks four feet high; oblong, oval, entire, downy, close-sitting leaves, and each stalk terminated by a loose spike of blueish flowers, appearing about Michaelmas.

[16]ASTER *Divaricatus.*

*Divaricated White American After.*] After with stalks about two feet high, divided at top into forked diverging branches, garnished with oval sawed leaves, and terminated by umbellated clusters of white flowers, appearing the beginning of September.

[17]ASTER, *Novæ Belgicus.*

*New Holland Starwort.*] After with stalks about four feet high; spear-shaped, slightly-sawed, close-sitting leaves; all the stalks paniculated, and all the branches of each panicle terminated by one blue flower, appearing the end of August.

[18]ASTER *Tripolium.*

*The Tripolium After, or Sea Starwort.*] After with stalks two feet high, producing unequal branches; spear-shaped, entire, fleshy, smooth leaves, and terminated by a corymbus cluster of blue flowers; in July and August.

Of the above species, the first four or five sorts are those most commonly cultivated.

All these perennial Asters have fibrous very spreading perennial roots, but annual stalks, which rising annually in spring, continue their growth all summer, flower and perfect seed in autumn, and then die down to the root.

*Their Culture.*

They disdain no common soil of a garden, and will succeed almost any where.

Most of them produce considerable tufts of stalks, forming a large bush, which being closely covered with leaves and flowers, they make a very showey appearance late in autumn, when other flowers are scarce, so are well calculated for large open compartments, or in assemblage with common shrubs, and to adorn the boundaries of home-lawns, or the borders of walks carried round out-shrubberies, &c.

The propagation of all the sorts is effected with facility, by dividing their roots in autumn, winter, or spring.

The root you intend to encrease from may either be taken up and divided, or with a spade separate part of it as it stands, and so divide that part into as many separate slips as it will admit of.

The smallest slip will readily grow and flower the following autumn, and in a year or two will encrease to a great bunch; and some sorts spread so considerably, that it is necessary to reduce them every two or three years, either by cutting in the roots on each side, or by taking them entirely up, and divide them, so plant a necessary supply of the best slips, and throw the rest away.

Most of the sorts may also be encreased by cuttings of their flower-stalks in May and June in a shady border, so that if any sort afford root off-sets sparingly, recourse may be had to this method.

The green-house sort is,

ASTER *Fruticosus.*

*Shrubby African Starwort, from the Cape of Good Hope.*] After, with a shrubby stem, growing a yard high, sending out side-branches, adorned with narrow leaves, in clusters from one point, and long naked foot-stalks from the sides of the branches, each supporting one blue flower, appearing early in March.

*Variety.*] Shrubby After with white flowers.

Both these varieties must always be kept in pots, in order to be wintered in a green-house.

Their

Their propagation is by cuttings of the young branches in ſpring or ſummer, planting them in pots, which plunge in a hot-bed, juſt to ſtrike the cuttings; afterwards move them to the full air during ſummer.

ASTRAGALUS, Milk-Vetch, including alſo the *Tragacantha*, or Goat's Thorn.

This genus conſiſts of herbaceous annual and perennial flower-plants, and ſome of ſhrubby growth, all of them adorned with winged leaves, and papilionaceous or butterfly-ſhaped flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, and five-parted at top. COROLLA is papilionaceous; the ſtandard long, erect, blunt, and reflexed on the ſides; the wings and keel of equal length, and ſhorter than the ſtandard. STAMINA, nine united filaments, and one ſingle, having roundiſh antheræ. PISTILLUM, a taper germen, ſubulate ſtyle, and blunt ſtigma. PERICARPIUM, a pod of two cells, and kidney-ſhaped ſeeds.

There are upward of twenty ſpecies; thoſe of them principally cultivated in the Engliſh gardens are,

[1]ASTRAGALUS *Alopecuroides.*

*Fox-tail Alpine Biennial Milk-Vetch.*] Aſtragalus with upright hairy ſtalks a yard high, ornamented with long-winged leaves, of about twenty pair of oval lobes, terminated by an odd one; and from the places of the leaves proceed large, cylindrical, cloſe-ſitting ſpikes, wholly covered with down, out of which appear yellow flowers, ſucceeded by woolly pods; flowers in June and July.

[2]ASTRAGALUS *Galegiformis.*

*Goat's-Rue-leaved Oriental Perennial Aſtragalus.*] Aſtragalus with upright ſmooth ſtalks four feet high, adorned with long-winged leaves, of about fourteen to twenty pair of oval lobes, ending in an odd one; and from the places of the leaves, long hanging ſpikes of yellow flowers, ſucceeded by triangular pods, appearing in June and July.

[3]ASTRAGALUS *Chriſtianus.*

*Great Yellow Oriental Perennial Milk-Vetch.*] Aſtragalus with erect ſtalks a yard high, large long-winged leaves, having many pair of oval lobes, ending in an odd one; and all along the ſtalks, from the angles of the leaves, proceed globular cloſe-ſitting cluſters of large bright yellow flowers, appearing in July.

[4]ASTRAGALUS *Cicer.*

*The Cicer Sylveſtre, or Globular Podded Perennial Aſtragalus.*] Aſtragalus with proſtrate ſtalks three feet long, winged leaves, of about ten pair of ſmall oval lobes, terminated by an odd one; and from the angles of the leaves grow ſmall ſpikes of yellow flowers, ſucceeded by globular ſwollen pods, flowering in July.

The firſt of theſe ſpecies is a biennial plant; the other three are perennials.

They are all very hardy, and will proſper in any of the common borders, or ſhrubbery clumps, and flower and perfect ſeed annually.

Their propagation is by ſeed. Sow it in ſpring in a bed or border of common earth, and the plants will ſoon come up; all they require is weeding till autumn, when they ſhould be tranſplanted into the places where they are to remain, when they will flower next ſummer.

As the Fox-tail Aſtragalus is apt to die away after it has flowered, ſome plants ſhould be raiſed annually.

[5]ASTRAGALUS *Tragacantha.*

*The Common Tragacanth Shrub, or Goat's-Thorn.*] Aſtragalus with many ſhrubby, procumbent, prickly, white ſtalks and branches, ſpreading every way a foot or two in length, adorned with winged, ſilvery-white leaves, of ſix, eight, or ten pair of lobes, ending in an odd one, having their foot-ſtalks terminated by a ſharp thorn, and white flowers in cluſters from the ſides and end of the branches, appearing in June and July, but not ſucceeded by ſeeds in England.

*Varieties of this are.*] Goat's-thorn with oval lobes to the leaves—with ſpear-ſhaped-lobes—with ſpear-ſhaped, pointed, very downy lobes—and with purple flowers, red flowers, &c.

This ſpecies and varieties retain their leaves long, and when they drop, the foot ſtalks remain in form of acute thorns, and as armature to the plants.

They ſucceed in the ſhrubberies in a warm dry ſituation, but as they are ſomewhat tender while young, ſome ſhould alſo be kept in pots, to have occaſional ſhelter of a frame or green-houſe during winter.

Their propagation may be effected eaſily by ſeed, if it can be procured, ſowing it in a bed of common earth in April; but in default of ſeed, they may alſo be encreaſed plentifully by ſlips and cuttings of their young ſhoots in April or May, planting them in pots, which plunge in a moderate hot-bed about ſix weeks, giving occaſional ſhade and water; and harden them gradually to the open air.

ASTRANTIA, Maſterwort.

This genus furniſhes two ſpecies of herbaceous perennials, growing from one to two feet high, ornamented with large divided leaves, and crowned by umbellate flowers.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, the flower is umbellate, each umbel formed, of four or five ſmaller ones: the general calix, or involucrum, conſiſts of eight or ten leaves; that of the ſmall umbrel, of about twenty, which are long, coloured, and ſpreading. COROLLA, each umbel have many florets, each formed of five erect, bifid, incurved petals. STAMINA, five filaments. PISTILLUM, an oblong germen, two ſtyles, and ſimple ſtigma. PERICARPIUM, an oval two-parted fruit, having two ſeeds.

The ſpecies are,

[1]ASTRANTIA *Major.*

*Great Black Maſterwoot.*] Aſtrantia with upright ſtalks about two feet high; many large, ſpreading, radical leaves, divided into five large, oval, deeply-ſerrated lobes; thoſe on the ſtalk trilobate and pointed, one leaf at each joint, and the top of every ſtalk and branch crowned by an umbel of flowers.

*Varieties.*] Great Maſterwort, with purple flowers—with white flowers.

[2]ASTRANTIA *Minor.*

*Leſſer Black Maſterwort.*] Aſtrantia with ſtalks about a foot high, digitated or fingered leaves, of ſeven or eight deeply ſawed ſegments, and all the branches terminated by the umbels of flowers.

The roots of theſe plants are large, fibrous, ſpreading, black without, and of many years duration.

The plants are very hardy; they are conſidered chiefly as plants of ornament; tho' they effect no great figure, they however afford variety in large gardens, where it is neceſſary to have many plants of eaſy culture.

Their propagation is by ſeed in the common ground, or by parting the roots, both of which may be performed any time, in open weather, from October till March.

ATRAPHAXIS.

This genus retains two ſhrubby plants of the green-houſe, garniſhed with ſmall ſimple leaves, and cluſters of two petalous flowers.

Claſs and order, *Hexandria Digynia.*

*Characters.*] CALIX, two-coloured permanent leaves. COROLLA, two roundiſh petals. STAMINA, ſix capillary filaments, and roundiſh antheræ. PISTILLUM, a compreſſed germen, no ſtyle, but two ſtigma. PERICARPIUM none, the ſingle ſeed being encloſed in the calix.

The ſpecies are,

[1]ATRAPHAXIS *Spinoſus.*

*Prickly Oriental Atraphaxis.*] Atraphaxis with a woody ſtem and branches four or five feet high, armed with ſharp ſpines; ſmall, ſpear-ſhaped, aſh-coloured, ſmooth leaves; and cluſters of white flowers from the ends of the branches, appearing in Auguſt, but no ſeed in England.

[2]ATRAPHAXIS *Undulata.*

*Waved-leaved Smooth African Atraphaxis.*] Atraphaxis with ſhrubby, trailing, unarmed ſtalks; garniſhed with ſmall, oval, waved, curled leaves; and greeniſh white flowers from the angles of the leaves, appearing in June and July, but no ſeed in England.

Theſe two ſpecies muſt always be kept in pots, to be moved to a green-houſe in winter.

Both the ſpecies are eaſily propagated by cuttings in ſpring and beginning of ſummer.

ATRIPLEX, Orach, or Arach; alſo the *Halimus*, or Sea-Purſlane Shrub.

This genus furniſhes herbaceous and ſhrubby plants; the former are conſidered chiefly as eſculent culinary herbs, the latter as plants of ornament, being adorned with curious ſilvery leaves.

Claſs and order, *Polygamia Monœcia.*

*Characters.*] Hermaphrodite and female flowers apart on the ſame plant. CALIX, five oval, concave, membraneous-bordered, permanent leaves in the hermaphrodites, and two large, plane, erect, acute ones in the female flowers. COROLLA, none. STAMINA, five filaments, and double antheræ. PISTILLUM, an orbicular germen, two-parted ſtyle, and reflexed ſtigma. PERRICARPIUM none, the ſeed being lodged in the calix.

The ſpecies are,

[1]ATRIPLEX *Hortenſis.*

*Garden Herbaceous Orach.*] Atriplex with large triangular leaves, and when it runs to ſeed, ſhoots up erect herbaceous ſtalks; flowers in June and July, and ripen ſeeds in Auguſt.

*Varieties.*] Garden Orach with dark green leaves—whitiſh green leaves—with purple leaves.

All theſe varieties are annual herbs; they were formerly much cultivated in kitchen-gardens, for culinary purpoſes, in the manner of ſpinage, and require exactly the ſame culture, the ſeeds being ſown where they are to

to remain annually in ſpring for ſummer uſe; alſo in autumn, to ſtand the winter for ſpring ſervice, hoeing the plants to four or five inches diſtance.

[2]ATRIPLEX *Halimus.*

*The Halimus, or Sea-Purſlane Tree.*] Atriplex with a ſhrubby ſtalk, branching out widely on every ſide, grows four or five feet high, ornamented with white, ſilvery, deltoid, entire leaves, being ſhaped like the Greek letter *Delta*, remaining all the year, and effects a ſingularly agreeable variety at all ſeaſons, but the flowers have no beauty.

It is a maritime plant of Spain, Portugal, and Virginia, but ſucceeds here in the full ground.

[3]ATRIPLEX *Portulacoides.*

*Common Sea-Purſlane.*] Atriplex with a ſhrubby ſtalk, ſending out numerous wide-ſpreading branches, grows three or four feet high, very buſhy, adorned with numerous, ovate, narrow, whitiſh, ſilvery leaves.

This is a ſea-ſide plant of England, and is ſometimes admitted in gardens.

Theſe two ſhrubby Atriplexes, by their ſilvery-coloured leaves, effect an agreeable contraſt, in aſſemblage with other ſhrubs, in any part of the pleaſure-ground.

Their propagation is by cuttings planted in a ſhady border in ſpring and beginning of ſummer; they will readily take root, and be fit to tranſplant in autumn.

ATROPA, *Belladona*, or Deadly Night-Shade; and the *Mandragora*, or Mandrake.

This genus retains two hardy herbaceous perennials, and one ſhrubby plant of the green-houſe, garniſhed with ſimple leaves, and bell-ſhaped flowers, cultivated in gardens more for ſingularity than utility or beauty.

The *Mandragora*, or Mandrake, ſo called from the feigned reſemblance of its large, long, fleſhy root, to the human figure, was always ranged as a diſtinct genus, till Linnæus lately diſcovered its characters to be the ſame as the *Atropa*, and ſo ranges it as a ſpecies of that genus.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, ſwelling, acutely five-parted at top, and permanent. COROLLA is monopetalous, bell-ſhaped, with a ſhort tube below, ſwelling, five-parted, and ſpreading above. STAMINA, five awl-ſhaped filaments attached to the baſe of the corolla, connected below, and large aſſurgent antheræ. PISTILLUM, a ſemi-oval germen, filiforme ſtyle, and oblong tranſverſe ſtigma. PERICARPIUM, a globoſe bilocular berry, ſitting on the calix, containing kidney-ſhaped ſeeds.

The ſpecies are,

[1]Firſt ſpecies, ATROPA *Belladona.*

*The Belladona, or Deadly Night-Shade.*] Atropa with herbaceous, ſtrong, branching, purple ſtalks, four or five feet high, ornamented with large, oval, entire leaves, placed alternate; and from the angles or places of the leaves, proceed many long foot-ſtalks, each ſupporting one bell-ſhaped, browniſh-purple flower, ſucceeded by large ſhining black berries of deadly quality.

It flowers and ripens its fruit from June or July until Michaelmas.

This is a wild plant of Britain, but being a robuſt, conſpicuous perennial, is admitted in many gardens, to form variety in the pleaſure-ground. It ought, however, to be diſpoſed with great caution out of the way of children, on account of the noxious quality of the fruit, which being the ſize and colour of black cherries, appear very beautiful and tempting; and taken internally, they cauſe a ſtupor, delirium, and convulſions, and without the ſpeedy and copious uſe of acids, ſuch as vinegar, juice of lemons, &c. ſoon prove mortal.

The freſh leaves of this plant applied to hard tumours, and ſchirrhous ſwellings on the breaſt, are a certain remedy.

The propagation of this ſpecies is effected abundantly by ſlips or off-ſets from the root in autumn or ſpring; alſo by ſeed in a bed of common earth, from which tranſplant the plants in autumn.

[2]Second ſpecies, ATROPA *Mandragora.*

*The Mandragora, or Mandrake Plant.*] Atropa with a very large, long, parſnep-like root; no ſtalk, but the root crowned with many large pointed leaves, devoid of foot-ſtalks, about a foot long, almoſt half as broad, ſpreading in a circular cluſter, and in the midſt riſe the foot-ſtalks of the flowers three inches long, each ſupporting one whitiſh-green flower, ſucceeded by large, round, yellowiſh berries.

It flowers in March or April, and the fruit ripen in July.

This ſpecies is very durable in root, which are ſaid to remain ſound and vigorous half a century at leaſt.

It is retained in many curious gardens, as a plant of ſingularity.

Its propagation is by ſeed, in a bed of light earth, ſown in autumn or ſpring, either where they are to remain, or the plants may be tranſ-

planted in autumn into different borders for variety, placing them in dry ground, where they will abide an age, encreaſe exceedingly in magnitude, and flower and perfect ſeed annually.

This is ſuppoſed to be the Mandrakes mentioned in Scripture, and the fruit are ſaid to have vaſt power in procuring fruitfulneſs to women.

Of the root of this plant many ridiculous ſtories have been invented by quacks, relative to its fancied reſemblance to the human form, it acquiring conſiderable ſubſtance, and ſtrikes three or four feet deep, dividing frequently into large, long, fleſhy forks, which impoſtors made to reſemble the legs, thighs, and arms of the human body, and ſhewed it about the country, advancing ſtrange accounts of its ſingularity, too idle to be regarded; ſuch as its ſenſation of feeling, by emitting groans at the approach of violence, and to cauſe inſtant death to him who ſhould attempt to root it out of the ground. So greatly were theſe impoſtures palmed upon the credulous formerly, that in default of the real *Mandragora*, Mandrakes, or images, were formed of the large roots of briony, effected by opening the earth in ſpring about a ſtrong-ſhooting young plant, without diſturbing the lower fibres, ſo fixing a figure-mould about it, then filling in the earth, and by autumn the root aſſumes the deſired form; they alſo ſometimes artfully carved a large root, as it grew, to a ſort of reſemblance, ſo filling in the earth again, and by the end of ſummer the carved parts would be cruſted over, ſo as to hide the artifice.

[3] Third ſpecies, ATROPA *Frutiſcens*.

*Shrubby Deadly Night Shade of Spain* ] Atropa with a ſhrubby very branching ſtalk, grows ſeven feet high, garniſhed with roundiſh oval leaves alternately, and footſtalks in cluſters from the wings of the leaves, ſupporting yellowiſh brown-ſtriped flowers, which are not ſucceeded by berries in England.

This plant muſt always be kept in pots, and wintered in a green-houſe.

It may be propagated by ſeeds procured from abroad, which muſt be ſown in pots in ſpring, and plunged in a hot-bed, juſt to raiſe the plants.

AVENUES In gardening Avenues are conſidered to be large ſtrait walks, bounded on each ſide with one or two rows of noble foreſt trees, deſigned ſometimes as a principal way from the common road to the manſion of a country ſeat, and often to form views, or to lead to different diſtricts.

In the acnient ſtyle of gardening, theſe kind of walks were conſidered as great ornaments; no country ſeat was without them, and many ſtill permit the old ones to ſtand: ſometimes ſeveral were extended from the manſion in different directions; frequently a grand one was extended directly from the main front of the dwelling to the neareſt common road; others were deſigned chiefly as ornaments, and ſome as views terminating in that of ſome diſtant natural object, or that of the united work of art and nature, and ſome were concluded by domeſtick works, as an obeliſk, temple, alcove, ruins, or other garden edifices; ſometimes by natural or artificial mounts, woods, groves, receſſes, bowers, &c which Avenues, when diſpoſed with propriety, and planted with different noble trees, aſſumed a grand appearance.

But modern planners rarely admit any ſuch thing as a regular Avenue in their deſigns; even often demoliſh entirely the old ones of a century or two ſtanding, copying nature to ſuch an extreme, that nothing having the appearance of art or regularity can be admitted.

Regular Avenues, however, about extenſive ſeats, detached in parks, &c. always exhibit an air of grandeur, though I ſhould adviſe to have the principal front of the manſion entirely open, or unincumbered with theſe or any kind of plantation; for it is a great abſurdity to hide a good front, and obſtruct the proſpect: no avenue can therefore be admitted with propriety in that part of the ground. A ſpacious lawn of graſs ſhould always be exhibited in due extenſion in the moſt conſpicuous fronts of the dwelling. See LAWNS. But in a direction from the wings, detached at ſome conſiderable diſtance, Avenues might with more propriety be introduced and extended on each ſide of ſpacious lawns, ſerving by way of boundary, and backed up next the lawn with ſhrubs and lower trees, diſpoſed irregularly, and if the Avenues are carried in an oblique direction, the lawn will widen gradually, and the proſpect will be more copious, or Avenues might be admitted at ſome diſtance from either end or back front of the dwelling, in either of which ſituations an Avenue may be extended towards any common road, village, or town, one or more ſerving as the common entrance or Avenue leading to the habitation, others by way of ornament, &c. and in extenſive ſituations, Avenues might occupy

cupy different parts at a diſtance directed towards woods, groves, or edifices, and particular diſtricts about an eſtate, which when of conſiderable width, and bounded on each ſide with the nobleſt progeny of the foreſt, gives an air of dignity to the ſite.

Theſe Avenues ſhould be planted with the ſtatelieſt trees; and an aſſemblage of different ſorts, effects the more agreeable variety.

The width of the Avenue ſhould never be leſs than ſixty feet, but when it is to be extended any conſiderable length, a hundred feet wide is not too much, eſpecially when we conſider that as the trees grow up, the branches on the oppoſite ſides continuing to approach each other, which by degrees greatly contract the view, ſo that if a conſiderable width is not at firſt adopted, the Avenue would in time appear very narrow and trifling.

The trees in the rows on each ſide ſhould be planted thirty feet diſtance at leaſt, that the different trees may have full ſcope to diſplay their heads, and each ſort exhibit itſelf conſpicuouſly, according to its own natural form.

The ſorts of trees proper for Avenues, are of the diciduous tribe; the elm, lime, platanus, beech, cheſnut, horſe-cheſnut, abele-tree, or white poplar, ſycamore, Norway maple, Virginia maple, walnut-tree, wild cherry-tree; all of which are of lofty growth; and an aſſemblage of all, or part, will have a fine effect diſpoſed in Avenues.

Sometimes evergreen trees are uſed for Avenues: where this is intended, the moſt proper ſorts are various ſpecies of the *Pinus*, or pine-tree, including all the ſorts of firs, moſt of which attain a great height and magnitude, with beautiful ſpreading heads, and are extremely ornamental.

Rural Avenues, as common ways or roads through a park, &c. to a habitation, may be contrived either in a direct line, or carried round in a moderate ſweep, or the courſe directed in two, three, or more, very gentle bends, or eaſy ſerpentine turns, each ſide ornamented with different ſorts of trees, thinly diſperſed in a rural taſte; that is, ſome placed ſingly, others in groupes of two, three, or more together, exhibiting them variouſly, ſome breaking forward, others ſtanding more back; and for the greater diverſity, may introduce here and there a clump of tall flowering ſhrubs, having, the whole, the ſingle trees, groupes, and clumps, ſo conſiderably detached, as to admit of a full proſpect of the adjacent lawns, fields, or plantations, during the whole excurſion of the Avenue.

The trees that form any ſort of Avenue, whether deciduous or evergreen, ſhould all be permitted to take their own natural growth.

AURANTIUM, the Orange-tree. See CITRUS.

AURICULA *Urſi*, Bears-ear, or Auricula. See PRIMULA.

AUTUMNAL *Plants*, Plants that flower in autumn.

AUTUMNAL SEASON. The Autumn ſeaſon being very often mentioned in the courſe of this work, it may be neceſſary to obſerve, that in regard to the numerous works directed to be done in that ſeaſon, we commonly conſider it to be from about the beginning or middle of Auguſt, till the latter end of November, in which period many works of ſowing, planting, and propagation, is ſucceſsfully performed.

As for inſtance, many ſorts of eſculent plants are ſown to ſtand the winter for ſpring, ſuch as cabbage, cauliflower, carrots, lettuce, ſpinach, onions; and in October and November, beans, peas; planting out alſo early cabbage-plants; likewiſe cauliflowers under hand and bell glaſſes, where they are to remain, and pricking others thick in frames, to ſtand till ſpring; planting out lettuces on warm borders, and in frames, to ſtand the winter; alſo celery in ſhallow trenches, for ſpring ſervice; making and ſpawning muſhroom beds, for winter and ſpring uſe.

Many ſorts of fibrous-rooted flower-plants are encreaſed at this ſeaſon, by dividing or parting their roots, particularly in the months of September, October, and November, when the flower-ſtems decay, and the ſlipped or divided parts will all flower the year following.

Likewiſe, from the middle of September until the middle or end of November, is a proper time to tranſplant from one place to another almoſt every kind of hardy fibrous-rooted perennials, as directed each under its proper genera.

It is alſo a proper time to plant all ſorts of bulbous flower-roots that were taken up in ſummer, which being now planted, exhibit an early ſpring and ſummer bloom.

Seeds of many ſorts of flowers are alſo now to be ſown, which do not grow ſo freely when ſown at other ſeaſons, as expreſſed in their reſpective places in the courſe of the work.

In this ſeaſon alſo, from the middle of September till the end of November, is the beſt time

time to plant cuttings, and make layers, for the propagation of numerous hardy trees and ſhrubs.

Seeds of many ſorts of hardy trees and ſhrubs are alſo to be ſown in October and November.

The principal Autumnal planting ſeaſon for all ſorts of hardy trees and ſhrubs, both fruit, foreſt, and ornamental kinds, is from about the middle of October to the end of November.

AXILLA, the angle formed by the ſtem and branch; and leaves proceeding immediately from that part are termed axillary leaves.

Likewiſe flowers proceeding from the angle, formed by the leaf and branch, are termed axillary flowers.

AZALIA, American Upright Honeyſuckle.

This genus furniſhes our ſhrubberies with two hardy, diciduous, flowering ſhrubs, of moderate growth, ornamented with oblong ſimple leaves, and funnel-ſhaped flowers in cluſters.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is ſmall, five-parted at top, coloured, and permanent. COROLLA is a funnel-ſhaped petal, having a long tube below, and divided at top into five reflexed ſegments. STAMINA, five filaments inſerted into the receptacle, and ſimple antheræ. PISTILLUM, a round germen, long permanent ſtyle, and blunt ſtigma. PERICARPIUM, a roundiſh capſule of five cells, and numerous roundiſh ſeeds.

The ſpecies are,

[1]AZALEA *Viſcoſa.*

*Viſcous Flowered White Azalea.*] Azalea with ſeveral ſhrubby branching ſtems, riſing three or four feet high, garniſhed with ſpear-ſhaped, narrow-baſed, rough-bordered leaves, in cluſters towards the end of the branches, and with all the branches terminated by white, hairy, glutinous flowers, coming out between the leaves in cluſters.

[2]AZALEA *Nudiflora.*

*Naked-flowered Red Azalea.*] Azalea with ſeveral woody branching ſtems, riſing ſeven or eight feet high, decorated with oblong, oval, ſmooth, entire leaves, placed alternate, and long footſtalks proceeding from the ſides of the branches, ſupporting cluſters of large red flowers, having the longeſt ſtamina.

The flowers of both theſe ſpecies are beautiful and fragrant, and bear ſome reſemblance to the common Honeyſuckle, being formed each of a ſingle petal, having a long tube, divided at top into five reflexed parts. See the *Characters.*

They flower annually in July, but never perfect ſeeds in England.

For purpoſes in gardening, both the ſpecies are well adapted for the ſhrubbery, and will ſucceed in any common ſoil, though they delight moſt in ſhady moiſt places.

As to their propagation, they not producing ſeed here, are commonly encreaſed by laying the young ſhoots in autumn, or ſpring; or that, as many ſtems or ſhoots generally riſe from each root, ſome of theſe may be taken off with roots, and planted either in nurſery rows, or where they are to remain.

The ſeeds of both ſorts are alſo often imported from America by the ſeedſmen, which ſhould be ſown in ſpring in a warm ſituation, or their germination may be facilitated by aid of a moderate hot-bed.

# B.

BACCA, a berry, defined to be a pulpy pericarpium, or ſeed-veſſel, generally round or oval, without a valve, incloſing ſeveral ſeeds, moſtly placed upon foot-ſtalks within the pulp, as in the gooſeberry, currant, raſpberry, &c.

The berry does not naturally gape or burſt for the diſperſion of ſeeds, being deſigned to be performed by means of animals.

By Linnæus, not only the currant, gooſeberry, raſpberry, ſtrawberry, &c. but alſo the very different fruits; the apple, pear, quince, medlar, love-apple, orange, lemon, and pine-apple, are all denominated berries.

BACCHARIS, Ploughman's Spikenard.

Of this genus are three exotic ſhrubs of the green houſe, growing five or ſix feet high, ornamented with ſimple leaves, and compound flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Cha-*

*Characters.*] Compound flower. CALIX is a cylindrical, acutely ſcaly, general cup containing many florets. COROLLA, the general flower is equal, the hermaphrodite and female florets are intermixed. STAMINA, five filaments in each hermaphrodite floret, and cylindrical antheræ. PISTILLUM, in all the florets an oval germen, filiforme ſtyle, and bifid ſtigma. PERICARPIUM, none; the ſeeds are one under each floret, crowned with down.

The ſpecies are,

[1]BACCHARIS *Ivafolia.*

*Iva-leaved American Baccharis.*] Baccharis with ſhrubby branching ſtems, four or five feet high; long, ſpear-ſhaped, venoſe, dentate-ſawed leaves; and whitiſh flowers from the ſides and ends of the branches, in July and Auguſt.

[2]BACCHARIS *Neriifolia.*

*Oleander-leaved African Baccharis.*] Baccharis with ſhrubby ſtems riſing ſix or ſeven feet high, branching out upward, garniſhed with ſpear-ſhaped ſtiff leaves, a little indented at top, and greeniſh-white flowers, in cloſe ſpikes from the ends of the branches, in July and Auguſt.

[3]BACCHARIS *Halimifolia.*

*Halimus-leaved Baccharis, or Virginia Groundſel-tree.*] Baccharis with a ſhrubby branching ſtem, riſing ſeven feet high, ornamented with oboval, emarginate-dentated, glaucous-coloured leaves, continuing all the year, and many ſmall white flowers, in September and October.

They flower here annually, and the firſt and ſecond ſorts furniſh ſeeds; but the third flowering late, rarely produce any in England.

Theſe three ſhrubs are generally conſidered as green-houſe plants; they are however ſo hardy as to be able to ſtruggle with our ordinary winter in warm ſhrubberies, in which departments they are ſometimes planted to take their chance; but as they are ſubject to be much cut in ſevere froſts, ſome of each ſort ſhould alſo be potted, in order to be houſed in winter.

The propagation of all three ſorts is by layers and cuttings of the young ſhoots, any time from March till Midſummer, in pots or the common ground, giving occaſional ſhade and waterings, particularly the cuttings, and they will be rooted and fit to tranſplant into ſeparate pots in autumn.

They may alſo be raiſed from ſeeds, in a bed of common earth, in March or April.

BACCIFERÆ *Planta*, Bacciferous, or Berry-bearing Plants, and ſuch that have a bacca, or berry, for their ſeed-veſſel or pericarpium. See PERICARPIUM.

BARBA, a Beard, alluding to bearded plants, being ſuch whoſe leaves or flowers are terminated by a bunch or tuft of down, or hairs. The *Meſembryanthemum Barbatum* furniſhes an example.

BARBATUS *Flos*, bearded, gaping, or ringent flowers.

A flower having two lips, the lower of which is the beard, *Barba*, and ſtands oppoſed to *Galea*, the upper-lip. Vide COROLLA *rignens*, and GALEA.

BARK-BEDS, Hot-beds formed of tanner's-bark, and ſuch that ſupport the moſt uniform and durable temperature of heat, and the beſt calculated hot-beds yet known, for the cultivation of all ſorts of tender exotics from the warm parts of America, Aſia, and Africa, that require the continual aid of artificial heat to maintain them in this country.

Theſe hot-beds, with a little aſſiſtance, as hereafter directed, often ſupport a regular temperature of heat almoſt a twelvemonth.

It is theſe bark or tan hot-beds that are univerſally uſed in hot-houſes, and are called the bark-beds, there being a cavity or pit formed within the hot-houſe almoſt its whole length, ſix or ſeven feet wide, and three deep, and walled round with brick; ſee HOT-HOUSE; and in which pit is made the bark hot-beds, the uſe of which is to plunge the pots in, containing all ſorts of tender exotics from warm countries; and by the aid of which principally, with occaſional aſſiſtance of actual fire, we are enabled to cultivate in the greateſt perfection that very curious exotic perennial, the *Bromelia Ananas*, or pine-apple; alſo all other tender plants from every quarter of the world; for by the joint aid of theſe bark hot-beds, and fire heat, we are able to imitate, within the hot-houſe, the temperature of diſtant climates, ſo far as to raiſe and exhibit in health, duration, and beauty, every known plant, herbaceous, or woody, from the warmeſt parts of the globe, which before the uſe of bark-beds were thought impoſſible to be cultivated in England.

Theſe bark hot-beds are alſo made in pits formed in the open ground, diſtinct and detached from the hot-houſe, which pits are walled round, having a frame of wood at top, for ſupport of glaſs lights, and are deſigned chiefly

chiefly for the propagation of tender plants from ſeed, cuttings, ſuckers, &c. without incumbering the hot-houſe, or ſtove departments, which are often ſo crowded, as not to admit of ſuch work; theſe are commonly called pits, or bark pits, and are very uſeful where there are great collections of tender exotics, and ſerve alſo as a nurſery for young Pine-apple plants, for the annual ſupply of the ſtove, or main pinery. See BARK PIT.

Bark hot-beds are alſo ſometimes uſed in the culture of melons, which, on account of their regular and durable heat, generally afford excellent crops: the Dutch practiſe this with great ſucceſs. See CUCUMIS *Melo*, the Melon.

Theſe kind of hot-beds are alſo uſed with great ſucceſs in forcing-frames, for the production of early fruit, ſuch as apricots, peaches, grapes, &c. See FORCING-FRAMES.

Hot beds made of this material, are conſiderably more regular and durable in heat than thoſe of dung, and not, like them, liable to injure plants by ſteam; and as to duration, they commonly maintain a due temperature of heat almoſt a year, with the aſſiſtance of forking or turning over two or three times, together with the addition, once, of about one third part of new tan; but they muſt be entirely renewed every autumn or ſpring, as hereafter directed.

This article tanner's bark, of which theſe hot-beds are made, is the bark of the oak-tree, chopped or ground to pieces for the uſe of the tanners, which after being uſed by them in their tan-vats, is fit for the gardeners purpoſe, wherewith to make hot-beds, for which, there being now ſo great a demand all over the kingdom, the tanners ſell it at a good price, which about London is commonly ſeven and ſix pence per cart-load of ſixty buſhels, or in proportion. The places about that city where the greateſt choice is to be had, is principally in the Borough of Southwark, where are numerous conſiderable tan-yards, particularly in the parts called the Grange-road, Long-lane, Barnaby-ſtreet, Bermondſey, and places adjacent.

In the choice of the bark or tan, obſerve there are different ſorts, ſuch as the large or coarſe, the middling, and the ſmall ſort, which laſt is the worſt of all; the large ſort is longeſt before it heats, and the heat is apt to be violent at firſt, though of the longeſt duration; the middle-ſize ſort heats moderately ſoon, and regular, ſeldom very violent, and is pretty durable; the ſmall ſort heats the ſooneſt of any, though more weak, and ſoon becomes earthy, whereby its fermenting property is ſoon exhauſted, and ſhould never be uſed alone, where any other can be poſſibly procured; this ſort however is now very common in the tan-yards, for the tanners find a conſiderable advantage for their uſe by grinding the bark ſmall, becauſe it goes the fartheſt

Therefore where there is choice, the middle ſize ſort is to be preferred, or a mixture of this and the large, and but as little of the ſmall as poſſible.

Likewiſe obſerve to procure ſuch that is freſh, i. e that has been about a week or fortnight, or at moſt not more than three weeks or a month out of the tan-pit, rejecting ſuch that have lain ſo long as to have become black and earthy.

When the tan is brought home, if it is very wet, it is eligible, previous to forming it into a bed, to diſpoſe it in ſmall heaps or ridges for two or three days, or till it is drained of the redundant moiſture, which would greatly retard its regular fermentation.

The time of year to make theſe beds is principally in autumn and ſpring. In hot-houſes, for pine-apple plants, &c. they are commonly made in September or October, to have a good heat during winter; but when they are required for the purpoſe of raiſing tender exotics from ſeed or cuttings, &c. they are generally made in ſpring, as alſo for melons, and forcing-frames.

The dimenſions of the bed is to be the width and length of the pit in which it is made, and a yard deep.

In making the bark-bed, the tan is to be thrown into the pit prepared for its reception, as before obſerved; and a hand or two beginning at one end, work the whole up regularly with the tan-fork to the bottom, carrying the bed to its full width and depth on before you; for it is not proper to tread much upon the bark when formed into a bed, which would render it too compact, and prevent its regular fermentation, raiſing the whole three or four inches higher than the kirb or top of the wall of the pit in which the bed is made, to allow for ſettling.

As ſoon as the bed is made, thruſt two or three long ſticks into the bark in different parts, to draw up occaſionally to feel their lower end, to inform you of the temperature of the heat.

In

In a fortnight, or perhaps in a little more or leſs time, the bed will be arrived at a due temperature of heat for the reception of the plants, of which you are to judge by the above mentioned ſticks, obſerving, if it is intended for pines, or other plants in pots, they are to be plunged immediately into the bark, there being no occaſion for earth thereon, as in dung hot-beds; and when you proceed to plunge them, it is eligible to lay a board acroſs to ſtand upon, to prevent treading the bark too cloſe; likewiſe having regard, if the heat is apparently violent, to plunge the pots only half way, leſs or more, as you ſhall judge neceſſary to preſerve the roots of the plants from being ſcorched, and when the vehement heat ſubſides, plunge them down to their rims.

The bed being thus made, it will ſupport its firſt heat a quarter of a year at leaſt, when if, by the trying ſticks, you find it upon the decline, it is to be revived by ſtirring up, or turning over the bark, which, if it is the large, or the middle-ſize ſort, it will not at this time require any augmentation of freſh tan. Previous to the turning, firſt take up all the pots, then beginning at one end, fork up the bark quite to the bottom, breaking the lumps, and turn the whole over, and directly plunge the pots as before; this operation will renew the heat, and ſupport it in a proper temperature two or three months longer, when the ſame work of turning, with the addition of about one third part of freſh tan is neceſſary, blending the whole together, continuing to repeat the ſame operation of turning as often as you ſhall find the heat decline; about twice or thrice in the courſe of the year is ſufficient.

It is always neceſſary, in March or April, to add about one third, at leaſt, of freſh tan, previouſly clearing out all the moſt crumbly or earthy old ſtuff at top and next the outſide, then throwing in as much new as will fill up the pit, fork the whole up neatly, old and new together.

Every autumn, in September or October, it is proper to renew entirely the bed in the hot-houſe and bark pits; for after it has been made ten or twelve months, the bark will be greatly exhauſted both in heat and ſubſtance, ſo as to become earthy, which, at the time you intend to make the new bed, ſhould be previouſly ſcreened, and all that paſſes through the ſcreen to be cleared away; ſo adding to the remaining old, as much new tan as will fill up the pit, then working the whole regularly together with the fork. See HOT-HOUSE. But where the old tan is very earthy, it is proper to clear it out entirely, and make the bed wholly of new materials.

BARK-PIT. In hot-houſes a Bark-pit is the cavity, wherein the bark hot-bed is made. See BARK-BED, HOT-HOUSE, &c.

A Bark-Pit is alſo an erection, covered with glaſs, formed ſeparately or diſtinct from the hot-houſe, but in a manner connected with it, as its chief uſe is by way of a nurſery for that department, being uſeful for raiſing all kind of tender exotics from ſeeds, cuttings, ſuckers, &c. and retaining them till a certain period, or till arrived at a proper ſtate of growth, to be removed to the ſtove, and is particularly uſeful for the young ananas, or pine-apple plants, in rearing and nurſing them till of a proper ſize to be placed in the ſucceſſion-houſe or fruiting-ſtove.

Theſe pits are commonly erected in a defended ſunny ſituation contiguous to the hot-houſe, and are formed moſt commonly with a wall of brick or ſtone, with flues behind, and with a frame of wood at top for the ſupport of glaſs.

The dimenſions are, the length from ten to as many feet as convenient, ſix or ſeven wide, and ſunk not more than eighteen inches in the ground in caſe of wet, and the whole to be walled round with brick from the bottom, raiſing it four or five feet in front, and five or ſix behind, the ends in proportion, with two flues near the upper part of the back wall, to make fires occaſionally in winter, to warm the air, and a timber plate or kirb, framed round the top with croſs-bars three feet four inches aſunder, for the ſupport of glaſs lights.

In this pit a bark-bed is made the whole length and width, and about a yard deep in tan, which will be ready for any ſort of tender plants, ſeeds, and cuttings, and its heat is continued by forking it over, and a ſmall addition of new tan, as directed under the article BARK-BED.

But when pits are required principally for raiſing tender plants from ſeed, cuttings, &c. in ſpring or ſummer, there need not be any flues or fire place.

BARLERIA. It contains ſeveral hot-houſe exotics, herbaceous and ſhrubby plants, riſing three or four feet high, having ſimple, oblong, or oval leaves; monopetalous, funnel-ſhaped, blue flowers, with four ſtamina, and one ſtyle.

They are rare in England, but may be raiſed from ſeeds in the ſtove.

BASELLA, Climbing Night-Shade of Malabar.

This genus retains two climbing, herbaceous, ſucculent, hot-houſe perennials, garniſhed with ſimple leaves, and monopetalous pitcher-ſhaped flowers.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX, none. COROLLA, a pitcher-ſhaped, fleſhy, permanent petal, connivent and ſix or ſeven-parted at top. STAMINA, five filaments attached to the corolla. PISTILLUM, a globular germen, three ſlender ſtyles, with oblong ſtigmas. PERICARPIUM, the permanent corolla aſſumes the appearance of a fleſhy berry, incloſing one ſeed.

The ſpecies are,

[1]BASELLA *Rubra.*

*Red Malabar Night-Shade.*] Baſella with climbing, ſtrong, ſucculent, deep purple, herbaceous ſtalks and branches, mounting, upon any ſupport, eight or ten feet high, adorned with heart-ſhaped, ſucculent, purple leaves, and foot-ſtalks from the ſides and ends of the branches, ſupporting reddiſh flowers.

[2]BASELLA *Alba.*

*White Small Malabar Night-Shade.*] Baſella with climbing, ſmall, ſucculent, very branchy green ſtalks; oblong-oval, waved, flaccid leaves; and long foot-ſtalks from the ſides of the branches, ſupporting white flowers.

*Variety.*] Baſella with ſmall purple ſtalks, and variegated leaves.

The flowers of both ſpecies appear from June till October, and are ſucceeded by plenty of ſeeds.

The plants are preſerved here in ſtoves, more for ſingularity than beauty.

They are propagated either by ſeed in a hot-bed in ſpring, or by cuttings in pots of dry light earth, plunged in the bark-bed in the ſtove, or any other hot-bed, moving the plants afterwards to the ſtove, and allow them ſupport.

BASKETS. For the uſe of gardeners, different ſorts of Baſkets are neceſſary for gathering the different products, and other uſes.

As for inſtance, that for the purpoſe of gathering all ſorts of ſallad herbs for family uſe, flat, ſhallow, chip or oſier Baſkets, without any handle, are the moſt convenient, which are in dimenſion, from about ten or twelve, to eighteen inches diameter, and two or three deep, which will commodiouſly hold, ſeparate, all the different herbs neceſſary to compoſe a ſallad for a family, and which are alſo uſeful for gathering many other ſorts of ſmall herbs. The Baſket-makers make vaſt numbers of them for the above uſes, which, about London, they ſell from one to two or three ſhillings per dozen.

For the purpoſe of gathering peas, beans, cabbage, carrots, and other crops required in any conſiderable quantity, there ſhould be ſtrong, deep, oſier Baſkets, of different dimenſions, ſomewhat of the form of a water-pail, and from about a peck to a buſhel ſize, with two ſtrong ſide-handles at top.

Baſkets of the above dimenſions are alſo very uſeful to uſe in weeding, both in the kitchen and pleaſure ground.

But in ſome places they make their garden Baſkets round, or of a half-globular form, with an arched or bow-handle croſs-ways at top, and are very uſeful for light work.

The kitchen-gardeners about London, for the purpoſe of carrying their ware to market, have ſtrong oſier Baſkets of different ſizes and ſhapes, for which they have different terms, as boats, junks, maunds, ſieves, &c. The boats are large flat Baſkets two or three feet broad, and eight or ten inches deep, with two handles at the rim, uſed chiefly to put up ſuch goods that cannot bear hard, or cloſe packing, ſuch as lettuce, celery, cauliflowers, ſmall ſallad-herbs, &c. alſo many ſorts of bunched eſculents, as bunches of young carrots, onions, leeks, fans of horſe-radiſh, ſticks of parſneps, hands of radiſhes, bunches of young coleworts, and ſuch like. Junks are from about half a buſhel to a buſhel ſize, flat-bottom, eight or ten inches deep, wideſt at top, where are four ſtrong handles, much uſed for packing kidney beans, which, with the help of large cabbage-leaves, they generally heap conſiderably more at top than there is within the Baſket. Maunds are upright narrow Baſkets about two feet deep, wider at top than bottom, having two handles, and uſually open round the middle of the ſides, and are uſed wherein to pack ſpinach, parſley, ſprouts, and other ſmall culinary herbs. Sieves are flat-bottomed, upright-ſided Baſkets, about a foot deep, without handles, and from about a peck to a buſhel meaſure in dimenſions, being equally as wide at bottom as the top, and are uſed for packing various ſmall plants; likewiſe fruit, particularly gooſeberries, currants, cherries, plums, &c. which differ-

rent kinds of Baſkets, though moderately cheap, ſtand the market-gardeners in an annual expence of from ten to twenty or thirty pounds, or more, according to their extent of ground.

Fruit-baſkets for domeſtic uſe, ſhould be of different ſorts; that for gathering ſmall fruit for table, ſuch as ſtrawberries, raſpberries, mulberries, gooſeberries, currants, cherries, &c. there ſhould be ſeveral ſmall, round, ſhallow, white Baſkets, of two or three different ſizes, holding in meaſure from about a quart to half a gallon, &c. from about ſix to ten or twelve inches diameter, and the rims not more than two or three deep, wider at top than bottom; ſo that every ſort of theſe ſmall fruit may be gathered in a ſeparate Baſket, and in that manner carried in to be put up in the deſert. For the larger kinds of fruits, ſuch as apricots, peaches, nectarines, plums, figs, pears, &c. it is proper to be furniſhed alſo with different-ſized, ſmall, ſhallow Baſkets, as above, at leaſt for the purpoſe of ſending in the fruit for the deſert, each ſort in its ſeparate Baſket, which ſhould be previouſly lined at bottom, and round the ſides and edges, thinly with vine leaves, the more effectually to preſerve the beauty of the fruit, and ſet it off to the beſt advantage, eſpecially if ſome are alſo thinly diſpoſed between the larger ſorts, as apricots, peaches, &c.

Pottle baſkets are the moſt convenient for ſending quantities of ſtrawberries, raſpberries, and mulberries, choicer ſorts of early cherries, and the moſt delicate ſorts of ſmall plums, to market, or to any diſtance; theſe are very ſmall, upright, chip Baſkets, holding about a quart, being ten or twelve inches deep, very narrow at bottom, and not more than four or five inches wide at top, where there is a croſs handle The London gardeners uſe vaſt quantities of them, buy them at ninepence or a ſhilling per dozen, which when filled with fruit, they pack many together in a large Boat-baſket, ſo ſend them to market on men's heads, or otherwiſe.

Sieve-baſkets, already mentioned, are the moſt uſeful for ſending large quantities of gooſeberries, currants, common cherries, grapes, plums, and other ſtone fruit, and ſoft pears, to market, which ſhould never be filled higher than the brim, placing a little fern, or ſhort hay, at top, ſo that, as being of an equal width at bottom and top, may, if requiſite, place one upon another, without preſſing upon the fruit. The cherry farmers in Kent and Hertfordſhire, &c. uſe all theſe ſort of Baſkets for ſending their cherries, and other ſoft fruit, to market.

Baſkets are alſo uſeful for packing many ſorts of plants in pots, when intended to be ſent in a growing ſtate to any great diſtance, for which uſe the Baſkets are prepared in width and depth, in proportion to that of the pot containing the plant; and if the plant hath a full head, the edge of the baſket is cloſely ſet round with long oſier, or willow rods; ſo when the plant is placed in the baſket, its head is tyed together neatly in two or three different parts; then the rods are gathered together at top, ſo as to ſurround and defend the head of the plant, which, when faſtened, will have a pyramidal form, and if it is cold weather, and the plants are of the tender kinds, mats ſhould alſo be neatly ſewed round the whole.

Large Baſkets, about three feet deep, and two and half diameter, are uſeful in pleaſure-grounds, for carrying off the mowing of ſhort graſs, leaves, &c. placing the baſket on a water-barrow, which Baſket will contain three times as much as the body of a common wheel-barrow; ſo that the work is done with more expedition, and with leſs wheeling backward and forward upon the graſs and walks.

In many places the gardeners make their own Baſkets, particularly in North-Britain, where, in time of hard froſts, when nothing can be done abroad, the men are occaſionally employed in making Baſkets for the enſuing year's ſervice, at which ſome are very dextrous; but they commonly make them all of a half globular form, with a bow handle croſs-ways at top, as before deſcribed.

For the principal materials for making Baſkets, ſee SALIX.

BASONS, or Reſervoirs of Water, for uſe and ornament in gardens.

For uſeful purpoſes, Baſons of water in gardens are eſſentially neceſſary for watering plants in ſummer, particularly ſuch that are obliged to be planted out in time of drought; alſo for watering beds of young ſeedlings of any ſort in dry hot weather, plants in hot-beds under glaſſes, and all ſorts of plants in pots; and that water expoſed to the ſun and air in Baſons, &c. is conſiderably more ſalutary for the growth of all vegetables, than raw ſharp water, drawn immediately out of wells: but ſometimes there are natural ponds, reſervoirs, or other waters, in the neighbourhood of gardens, ſo conveniently ſituated for watering, as to render the expence of making

a Baſon, merely for that purpoſe, unneceſſary.

For ornament, regular Baſons of water were in great eſteem in formal deſigns of gardens, and were commonly ſituated in large opens, or centres, at the termination or meeting of ſeveral walks; they were often ſo contrived, as to have playing fountains, or jets d'eau, as the French term them, in the middle, with Neptune and his train, and other devices; but the regular figure of a Baſon, &c. is now thought too formal to be admitted in our preſent deſigns in imitation of nature: this, however, is according to the fancy of the owner or planner of the deſign, ſince the form and dimenſion may be varied at pleaſure. The figure was commonly either circular, oval, octagonal, or ſquare, which, when of moderate dimenſions, were called Baſons, but if large, were termed pieces of water; but a Baſon might be formed according to nature, in any well-deſigned irregular figure, ſo as to have a deſirable effect.

One great article in making Baſons, or any pieces of water, is to conſider whether a proper ſupply of water is to be obtained at all times of the year.

Another thing is the means of making them hold water completely at all ſeaſons.

This is done the moſt effectually by laying the bottom and ſides of the cavity thereof with ſtrong clay, twelve, fifteen, or eighteen inches thick, according to the quality of the natural ſoil; for the more the ſoil inclines to a looſe or ſandy texture, the greater thickneſs of clay muſt be allowed; but where the ſoil is naturally loamy or clayey, there will be little difficulty in making it hold water with a moderate thickneſs of additional clay.

In default of clay for the above purpoſe, chalk is ſometimes uſed in countries where it abounds, firſt forming it into a powder, then forming into a ſort of mortar, and with this the bottom and ſide walls are formed, beating and ramming it hard, obſerving the thickneſs as above.

Some alſo, inſtead of clay, work the bottom and ſides a foot thick with maſonry of brick or ſmall ſtones laid in terraſs, and plaiſter it over with two or three inches thickneſs of cement, which is two thirds of powdered tile to one of lime, beating it well with as little water as poſſible, into a ſtrong mortar, and after this is laid on, rub it over with oil or bullock's blood, and it hardens under water like ſtone.

The depth of Baſons, or any ornamental piece of water, need not be more than three feet, though ſome are conſiderably deeper; but four feet at moſt is depth enough, even when intended to have a boat thereon, or to keep fiſh in for breeding. The ſides of the cavity of the Baſon ſhould be formed with a gradual ſlope, from the top of the circumference to the intended depth, and the whole laid with clay, to render it water-tight, as before obſerved, and a few inches of gravel over that, to preſerve it, and render the water clear; and the ſurrounding ſurface of ground ſhould be laid with graſs from the edge of the water to ſome conſiderable diſtance each way, though in the old deſigns, perpendicular walls of maſonry laid in terraſs, were often formed round the ſides of the cavity, with a ſtone coping at top, correſponding with the general ſurface.

No high banks, or ſtiff ſlopes, ſhould be raiſed as boundaries to a Baſon, or any piece of water intended for ornament, to obſtruct the diſtant proſpect thereof; and if ſo that the water will unavoidably lie low, it is proper to ſlope off the ground gradually from ſome diſtance on every ſide to the intended ſurface of water, ſo as the ſuperficies of the circumference may more apparently correſpond with the general ſurrounding ſurface; for the ſlope to the water, if neceſſary to have any, ſhould be eaſy and natural, that the whole ſurface of water may appear as conſpicuous as poſſible at ſome diſtance, and the whole ſo contrived, that the water may always appear nearly as high as the ſuperficies of the margin of the Baſon.

The ſituation for ornamental Baſons, &c. ſhould be in ſome conſpicuous part, as far as may be conſiſtent with the means of having it properly ſupplied with water at all ſeaſons, eſpecially in ſummer, when it is the moſt deſireable both for uſe and ornament; and where a large work is intended, we ſhould alſo contrive it in the moſt eligible part, where as little digging as poſſible is neceſſary to form the cavity.

As to the dimenſions or ſize, that, if deſigned merely for the uſe of watering plants, from ten to fifteen or twenty feet diameter may be ſufficient; but when required for ornament, it may be any ſize or form, in proportion to the extent and form of the garden, or according to the ſupply of water that can be eaſily obtained, or the nature of the ſoil for holding the water; for where water is ſcarce, or that the ſoil is looſe and ſandy,

nothing

nothing very extenſive ſhould be attempted, as the bringing clay from a diſtance to lay a large Baſon fifteen or eighteen inches thick, as muſt be the caſe in light ſandy ground, would be attended with a conſiderable expence; and if, after all, water was not to be had in ſufficient quantity to keep the Baſon always full, how great would be the diſappointment? But where water is copious in the neighbourhood, either in an adjacent river, brook, or running ſpring, ſo ſituated that a ſufficiency can be readily conveyed at a moderate expence to the part of the ground required, a Baſon of a more capacious dimenſion may be undertaken; and if, with the above circumſtance of plenty of water, there is a natural loamy or clayey ſoil of proper depth, they are particular advantages, and in which caſes, Baſons of conſiderable extent are ſometimes eaſily formed with very little artificial claying, and ſome without any, where there is a good natural depth of clay, and a large ſupply of water: however, in looſe, hollow, ſandy, or any light ground, a good coat of clay muſt be allowed all over the bottom and ſides.

In ſetting out the dimenſions of the Baſon, obſerve, that where a full coat of clay is neceſſary, it muſt be ſtaked out three feet ſix inches, at leaſt, wider than its intended width, to allow for a fifteen inch wall of clay on each ſide, and five or ſix inches of gravel over the clay; it ſhould alſo be twenty inches, or two feet deeper than you deſign the depth of water, becauſe the bottom ought to be clayed fifteen or eighteen inches thick, and five or ſix of gravel.

Particular care ſhould be obſerved to ſtake the ſuperficies of the circumference perfectly level, that the water may ſhow regular diſtance every way from the margin. The manner of taking the level is as directed under the articles LEVELLING and WATER.

In digging out the cavity of the Baſon, begin towards the middle, and excavate the earth to the intended depth, as above, then work off the ſides regularly with a moderate ſlope from the edge of the circumference to the bottom of the Baſon.

When the cavity of the Baſon is formed, let it be well rammed and ſmoothed, then the clay is to be brought in, which ſhould have been previouſly well wrought over and trod; ſee CLAY; and begin laying the bottom in the middle, being careful that no ſtones, ſticks, or ſuch materials, be mixed therewith, to occaſion fiſſures to let off the water; ſpread it regularly, a little at a time, and tread it with men's naked feet, caſting water thereon frequently, ramming it alſo from time to time with wooden rammers, obſerving, if it is looſe ground, lay it fifteen or eighteen inches thick, and ſee that every part be well kneaded, that there be not the leaſt vacancy, for the water will eſcape at the ſmalleſt cranny, and occaſion great trouble hereafter. During the work, if the weather is dry, cover the clay, as you lay it, with mats or moiſt litter, to prevent its cracking, continuing the claying regularly each way from the bottom to the top of the circumference of the Baſon; and as ſoon as the whole is clayed, cover it immediately with a ſtratum of coarſe gravel four or five inches thick, which ſecures the clay, and renders the water always clear; and when thus far finiſhed, let the water in as ſoon as poſſible. Then proceed to finiſh the ſuperficies of the circumference, and lay it all round with turf from the water-edge to ſome conſiderable diſtance every way, as the ſituation ſhall admit, obſerving to lay it as far down on every ſide as the water will apparently ſtand, but not ſo as to form any ſlope, diſtinct from that of the immediate ſurrounding ſuperficies; for if any at all is neceſſary, it ſhould be contrived in one regular ſlope, which is the more agreeable to character, as the ſurface of water will more apparently correſpond with the circumjacent ſurface of the ground, and appear the more conſpicuous at a diſtance; ſo that when the ſurface of the water lies unavoidably much lower than the general ſurface, the ground on every ſide ſhould be ſloped off gradually to ſome conſiderable diſtance, as before hinted, that the deſcent to the water may be as eaſy and natural as poſſible, ſo as to admit of walking with pleaſure upon any part thereof.

Sometimes, in regular pieces of water, one or more artificial ſwells, in imitation of nature, are artfully diſpoſed in particular parts near the ſide, ſo as to have a characteriſtic appearance.

BASS, among gardeners, is pieces of the threads or ſtrings of garden baſs mats, extremely uſeful as ligaments in the culture of numbers of plants, and the moſt cheap and ready bandage for the uſe of gardeners.

As for inſtance, it is the beſt bandage that can be uſed for binding grafts and buds; alſo for the tying up the ſtalks or ſtems of moſt ſorts of flowering plants, and which, if freſh, will

will endure a year; likewiſe is very uſeful in the kitchen garden for many purpoſes, ſuch as tying up the leaves of early cabbages, lettuce, endive, &c. to whiten and promote their heading; alſo for bunching up various ſorts of pot and medical herbs for winter ſervice, and for many other uſes.

The Baſs for all theſe purpoſes ſhould be quite freſh, not taken from ſuch old mats as have been occaſionally uſed in the garden; and that where there is much tying, it is eligible to allot a mat or two entirely for that purpoſe, keeping it in the dry, and not drawing the Baſs, as is often practiſed, from the mats that are deſigned for other uſes, which ſoon ſpoils them.

When it is wanted for tying, it ſhould be drawn out regularly, and cut into equal lengths; and to render it more pliable and tough, ſhould be dipped in water, then the gardener ſhould tuck it in his apron-ſtring, where it will be ready for uſe.

BASTERIA, All-ſpice. See CALYCANTHUS.

BAUHINIA, Mountain Ebony.

This genus comprehends ſeven or eight ſpecies of tender exotic ſhrubs and trees, producing pentapetalous flowers in ſpikes, having ten ſtamina, and a declinated ſtyle.

They are rare in England; the following are cultivated in ſome of our ſtoves.

[1]BAUHINIA *Aculeata*.

*Prickly Bauhinia, or Indian Savin.*] Bauhinia with a prickly ſtem, riſing fifteen feet high, having irregular branches, roundiſh emarginate leaves, emitting a balſamic odour like the ſavin-tree, and ſpikes of yellow flowers.

[2]BAUHINIA *Tomentoſa*.

*Tomentoſe Bauhinia.*] Bauhinia with a ſmooth ſtem and branches, growing fifteen or eighteen feet high, heart-ſhaped tomentoſe leaves, having two ſemi-orbicular lobes, and long ſpikes of yellow flowers.

They are propagated by ſeeds from abroad, aſſiſted by a hot-bed, or the bark-bed in the ſtove, where the plants muſt always remain.

BEDS are ſmall compartments of ground, of three or four feet breadth, very neceſſary in the culture of many ſorts of plants.

In kitchen-gardens, it is eligible to ſow and prick out many ſorts of ſmall plants in Beds, having narrow alleys between, for the greater convenience of weeding, watering, gathering, &c. without trampling on the crops; as, for example, the ground intended for aſparagus and ſtrawberries ſhould be divided into four feet wide Beds, with eighteen inches, or two feet alleys between; onions are alſo cultivated to the beſt advantage in four feet wide Beds, having ten or twelve inch alleys; the different ſorts of lettuce and endive ſhould alſo be ſown and tranſplanted into ſeparate Beds; alſo early radiſhes, when intended to cover them occaſionally. All ſorts of plants that are particularly intended for tranſplantation, ſhould always be ſown in beds or narrow borders, ſo as to admit of ſtanding to clean, water, and draw the plants, without treading upon them; alſo, for the ſame reaſon, all plants neceſſary to be pricked out previous to their final tranſplanting, ſhould alſo be pricked in Beds, ſuch as celery, cabbage, cauliflower, broccoli, &c. aromatic and medical herbs of all ſorts ſhould alſo, for the general part, be diſpoſed in Beds with twelve or fifteen inch alleys between, particularly mint, thyme, ſavory, marjoram, ſage, hyſſop, baum, penny-royal, tanſey, tarragon, feverfew, rue, &c. which method of bedding all the ſorts of plants above hinted, is not only more commodious for doing the neceſſary work without prejudicing the plants, but alſo has an air of uniformity, which is ever to be obſerved in a kitchen garden.

The proper dimenſions of Beds in this diſtrict, is four feet, or four and a half in width, the length at pleaſure, with intervening ſhallow alleys, nine, twelve, or fifteen inches wide, ſo that a perſon in the alleys may eaſily reach half acroſs the Bed, to do the neceſſary work to the plants, &c. without trampling them, or treading the ground hard.

In flower-gardens, when deſigned ſeparately from the general pleaſure ground, ſhould be wholly divided into regular parallel Beds, of three or four feet width, with eighteen inch, or two feet alleys, eſpecially when intended chiefly for the curious ſorts of bulbous rooted flowers, ſuch as tulips, hyacinths, &c. alſo for ranunculas, anemones, and other choice ſorts, that, by being depoſited together in Beds, they can be occaſionally covered in winter, and the flowers ſcreened from the ſcorching ſun in ſummer. Theſe Beds ſhould be neatly edged with box. See BUXUS and EDGINGS.

The Beds of a regular flower-garden may alſo be laid out parterre faſhion in the Chineſe taſte. See PARTERRE.

A flower ſeminary, or nurſery for raiſing all ſorts of flowers from ſeeds, ſlips, cuttings, parting-roots, &c. ſhould alſo be divided into three or four feet wide Beds.

In

In nurſeries for trees, the ground intended for the reception of ſeeds and cuttings of all ſorts of hardy trees and ſhrubs, ſhould alſo be divided into three or four feet Beds, with twelve or fifteen inch alleys between, for the reaſons above-mentioned.

Beds ſhould not in general be raiſed but very little higher than the alleys, unleſs in caſes of too copious moiſture; but otherwiſe, the ſurface of Beds ſhould not be more than two or three inches, at moſt, higher than the level of the alley; for, when raiſed conſiderably, the alleys aſſume the appearance of trenches, and have a diſagreeable look.

BELLIS, that beautiful little perennial the Daiſy.

The garden Daiſy, in all its forms and colours, are varieties only of one ſpecies, and that the common white field Daiſy that adorns the meadows and paſture grounds in moſt parts of Europe, is ſuppoſed to be the parent of them all.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] Compound radiated flower. CALIX, a double ſeries of ſmall equal leaves. COROLLA, numerous ſmall, tubular, hermaphrodite florets compoſe the diſc, and flat female florets the radius, and a ſingle naked ſeed under each floret. See COMPOSITUS *Flos.*

But in the full double flowers, the radius, or female florets, are encreaſed to the very centre, and form the doubleneſs. See PLENUS *Flos.*

The ſpecies is,

BELLIS *Perennis Hortenſis.*

*Perennial Garden Daiſy.*] Bellis with a fibrous perennial root, crowned by numerous ſmall, oval, evergreen leaves, in a large tuft cloſe to the ground; and amongſt them riſe many naked flower-ſtalks, four or five inches high, each ſupporting one flower.

*Varieties of this are*] Common garden Daiſy with double white flowers—with double red flowers—with double white and red ſtriped flowers——with variegated flowers——double ſcarlet flowers—double pyed flowers—double quilled or fiſtular flowers—double white cock's-comb-ſhaped flowers——double red cock's-comb-ſhaped flowers—double ſpeckled flowers—Proliferous, or Hen and Chickens Daiſy, the moſt ſingularly curious of all, it being a large double flower, ſending out many ſmall ones immediately from its ſides all around, each ſupported on a ſhort foot-ſtalk, the whole regularly ſurrounding their common parent, appearing very ornamental.

All theſe varieties flower abundantly in April, May, and June, and have an exceeding pretty effect, when properly diſpoſed in the fronts of borders in aſſemblage with perennials of ſimilar growth. See PERENNIAL PLANTS.

They are extremely hardy, and proſper in almoſt any ſituation and ſoil.

With regard to their diſpoſition, ſome plant them to form edgings, but theſe ſoon become irregular, in which order of arrangement, however, the flowers are the moſt conſpicuous, though, for the ſake of diverſity, I ſhould alſo adviſe diſpoſing many of them in different parts of the borders, towards the front, to form round patches or tufts a yard or two diſtance, planting the different varieties alternately, to effect the greater variegation.

The propagation of all the varieties is by dividing or ſlipping the plants in autumn or ſpring, and the ſmalleſt ſlip having a fibre, will readily grow, and in one ſeaſon encreaſe to a large tuft; if, however, they are intended to make as great a ſhow of bloom as poſſible, they ſhould not be divided too ſmall, and the ſlips may be planted at once where they are to remain.

As theſe plants encreaſe conſiderably into bunches, they ſhould be tranſplanted and ſlipped every year, or at leaſt every ſecond autumn.

This is alſo neceſſary to preſerve the double ſtate of the flowers, as, if permitted to remain long unremoved and ſlipped, they become ſmall and ſingle like the common ſort.

The gardeners about London, who raiſe vaſt quantities to ſupply the markets in ſpring, always ſlip their ſtore plants annually in autumn, in September or October, and plant them together in beds or borders, in rows ſix inches diſtance, planting ſome alſo in warm ſunny borders, to facilitate an early bloom, for they always carry the plants to market when in flower, and the ſooner this is effected in ſpring, the greater price they fetch.

At each time of ſlipping, always encreaſe from the largeſt and fulleſt doubles; and thoſe that diſcover any ſigns of degeneracy to ſingles, caſt entirely out of the garden.

BERBERIS, the Barberry-ſhrub, or Pipperidge-buſh.

This genus comprehends hardy deciduous ſhrubs, having ſimple oval leaves, and ſmall hexapetalous flowers, moſtly in ſmall bunches.

Claſs

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, ſix concave coloured leaves, alternately ſmaller and larger. COROLLA, ſix ſmall, oval, concave petals, and two coloured nectariums attached to the baſe of each petal. STAMINA, ſix erect, compreſſed, blunt filaments, and two antheræ attached to their apex. PISTILLUM, a long cylindric germen, no ſtyle, but a broad, orbicular, bordered ſtigma. PERICARPIUM, a cylindric, blunt, umbelicated berry, of one cell, containing two ſeeds.

The ſpecies are,

[1]BERBERIS *Vulgaris.*

*Common Barberry.*] Barberry with ſhrubby woody ſtems and branches, growing eight or ten feet high, armed with thorns by threes; oval ſlightly-ſerrated leaves, placed alternate; and yellow flowers, in numerous ſmall long cluſters from the ſides of the branches, ſucceeded by cluſters of ſmall, bright, red berries, in autumn.

*Varieties of this are*] Common Barberry with red fruit, having ſtoney ſeeds—with red ſtoneleſs fruit—with white fruit—with black ſweetiſh fruit.

The root of all the varieties is yellow; alſo the inner bark of the ſtem and branches.

[2]BERBERIS *Cretica.*

*Cretan Box-leaved Barberry.*] Berberis with many ſhrubby ſtalks three or four feet high, armed with thorns at every joint, ſmall oval leaves, and ſlender foot-ſtalks, each having one flower, but no fruit in England.

The firſt ſpecies, *Berberis Vulgaris*, is the moſt commonly cultivated in the Engliſh gardens, and the red fruited varieties moſt of all; it grows wild in many of our woods and hedges, but has been long admitted an inhabitant of gardens, both as an ornamental ſhrub, and for the ſake of its red fruit for domeſtic uſes, which, growing in numerous little cluſters, have a very ornamental appearance in autumn, and when fully ripe, are a curious and very wholſome pickle; for which uſe, the ſtoneleſs red ſort is in moſt eſteem; the bunches of red fruit are alſo in much requeſt for garniſh to diſhes, and where numbers of the ſhrubs are cultivated, the fruit afford a good repaſt for birds.

They flower in May, and the red ſorts ripen fruit abundantly in September.

They are excellent furniture for wilderneſs or wood-works, or any of the large ſhrubbery clumps, in aſſemblage with common deciduous ſhrubs, and all the culture they require is, to reduce with a knife any rambling ſhoots. See SHRUBBERY.

But to have fruit as large and fine as poſſible, ſome plants may be diſpoſed ſingly, trained with a ſingle ſtem four feet high, then permitted to branch out to form a head, and take its natural growth, only cutting out luxuriant ſhoots and ramblers.

Their propagation may be effected by ſuckers ariſing annually from the root.

Likewiſe abundantly by layers in the common way, any time from October till March, which will be rooted and fit to tranſplant the following autumn; cuttings of the young ſhoots planted in autumn, will alſo many of them ſtrike.

They may likewiſe be raiſed plentifully from ſeed, in a bed of common earth, in autumn, though the plants will probably not appear until the ſecond ſpring.

BETA, the Beet.

This genus furniſhes ſeveral varieties of uſeful culinary herbs, and eſculent roots, of the kitchen-garden.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, a five-leaved permanent cup. COROLLA, none; five ſtamina; a germen under the receptacle, and two ſtyles, ſucceeded by a unilocular capſule, having one ſeed ſurrounded by the calix.

There are two or three ſpecies, one of which grows wild on the ſea ſhores, and is ſeldom admitted in gardens.

The garden kinds are,

[1]BETA *Cicla.*

*The Common Culinary Beet*] Beta with a ſmall, oblong, white root, producing from its crown many large, oblong, ſucculent leaves, on broad foot-ſtalks; anderect branching ſeed-ſtems and ſtems two or three feet high, garniſhed with cloſe-ſitting leaves, and long ſpikes of greeniſh flowers.

*Varieties of this are*] Common green-leaved Beet—white-leaved Beet—Chard, or great white Swiſs Beet, having very broad leaves, with thick foot ſtalks and ribs.

Theſe varieties often vary from one to the other, that the ſeed of one frequently producing ſome of each ſort, though, by care in ſaving the ſeed, the difference may be continued.

[2]BETA *Rubra.*

*The Red Beet.*] Beta with a large, red, eatable root, crowned by many large, ſucculent, dark-purple leaves; and when it ſhoots, ſends

ſends up erect ſtalks and branches, terminated by long ſpikes of flowers.

*Varieties of this are* ] Common red Beet with a large, longiſh, dark-red root—turnep-rooted red Beet—with a red root and green leaves—with a yellow root.

The firſt of theſe four varieties is to be preferred for general culture.

*Culture of the Common Sort and Varieties.*

The firſt ſort, Common Beet, and varieties, are choice culinary herbs, whoſe property reſides in their large ſucculent leaves, which are excellent for ſoups, &c. alſo to boil and eat like ſpinach; and the Chard Beet is in much eſteem alſo, for the ſtalks and ribs of its large leaves, which being diveſted of the leafy part and peeled, are great improvers of ſoup, alſo for ſtewing, and to be dreſſed and eaten like aſparagus, and the leaves themſelves are fine pot herbs, as above, for all of which uſes the ſeveral varieties of this ſpecies may be obtained almoſt the year round; for as often as the large outer leaves are gathered, the root continues ſending up a freſh ſupply from the centre, not only in ſummer, but alſo in autumn, winter, and ſpring, in open weather.

All the varieties of this ſort are propagated by ſeed ſown annually in March or April, in the places where the plants are to remain.

They ſucceed in any common ſoil of the kitchen-garden, allowing each ſort a ſeparate plat or bed. Let the ground be dug one ſpade deep in the uſual way; the ſeed may then either be ſown broad-caſt on the ſurface, and raked in; or, as it is a large ſeed, ſhallow drills may be drawn ſix inches diſtance for the common green and white varieties, but almoſt double that for the Chard Beet, ſowing the ſeeds therein thinly, and rake the earth over them about an inch deep, and trim the ſurface ſmooth.

The plants will come up in about a month; when theſe have leaves an inch or two broad, they ſhould be hoed to thin them and deſtroy weeds, cutting out the common green and white ſorts to about ſix inches diſtance; but the Chard Beet ſhould be allowed ten or twelve inches room every way, that their large ſucculent leaves may have full ſcope to ſpread.

They will be in perfection for uſe in June and July, and continue till next ſpring, obſerving, when you gather them, always to take the largeſt outſide leaves; the others will come in for uſe in their turn, and an abundant ſucceſſive ſupply will riſe duly in the centre from the root.

*Culture of the Red Sort.*

The ſecond ſort, *Beta Rubra*, is highly valued for its large red root, which in the common variety often grow twelve or fifteen inches long, and three or four inches thick, or more, upward; and thoſe that are of the largeſt growth, and darkeſt red colour, are the moſt valuable: theſe roots being tender, ſweet, and palatable, are boiled, ſliced, and eaten cold, &c. are alſo ſliced and ſcraped in ſallads, both as an eatable ingredient, and by way of garniſh; ſlices of the root are alſo in requeſt as garniſh to diſhes, and they are alſo uſed as a pickle.

Theſe roots are in perfection from the end of Auguſt until March or April, when they will ſhoot, and become ſticky.

This ſort is raiſed from ſeed annually in March or April, in the place where the plants are to remain, being careful to procure that of the beſt dark red ſort.

It ſhould be allowed a light, rich, deep ſoil, in an open expoſure.

The market-gardeners often ſow this ſort thinly among their crops of onions, carrots, &c. that are to be drawn off while young; ſo that when theſe are gone, the Beets commence a full crop.

I ſhould however adviſe to ſow the principal crop ſeparate, which, in the end, will be found to be the beſt culture. Let the ground be dug one good ſpade deep at leaſt, and well broken, and ſow the ſeed directly, which may either be ſown broad-caſt on the ſurface, ſo tread and rake it in, or, as obſerved of the firſt ſort, as the ſeed being large, that in order to bury it more regularly, it may be ſown in drills drawn an inch deep, and ten or twelve diſtance; or you may dot or prick it in, as often practiſed, with a blunt dibber, in lines the above diſtance, making the holes an inch deep, and eight or ten aſunder, at leaſt, dropping two or three ſeeds in each hole, though only one good plant muſt be left in each place. In May or June, when the plants of either method of ſowing have leaves an inch broad, they will require thining and cleaning from weeds. Chuſe a dry day, and with an hoe cut up all weeds, and ſet out the plants ten or twelve inches diſtance, leaving no where two or more together, repeating the work occaſionally to kill weeds till the plants cover the ground.

Some of the roots will be fit to take up for uſe about the end of Auguſt, though they will not attain perfection until October.

In November a quantity of roots ſhould be taken up, their tops trimmed off not too cloſe, and then laid in ſand or dry earth under ſhelter, to be ready for winter ſervice.

*Of ſaving Seed from both Species.*

To ſave ſeed of all the varieties, either mark ſome of the beſt plants in ſpring to be left to run up, or may be tranſplanted in February or March into a convenient place, to have ſhelter from winds; they will ſhoot up ſtalks in May; in June ſupport them with ſtakes, and the ſeed will ripen in September.

BETONICA, Betony.

The plants are herbaceous fibrous-rooted perennials, having ſimple leaves, and annual ſtalks from one to two feet high, terminated by ſpikes of ſmall ringent flowers; eſteemed, ſome as medical plants, and ſome for variety in gardens.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX is monophyllous, tubular, five-parted, and permanent. COROLLA is ringent, with a cylindric incurved tube, the upper-lip roundiſh and entire, the lower one three-parted, the middle part broad and emarginated. STAMINA, two long and two ſhort filaments, and roundiſh antheræ. PISTILLUM, a four-parted germen, awl-ſhaped ſtyle, and bifid ſtigma. PERICARPIUM none, four naked ſeeds lodged in the calix.

The ſpecies are,

[1]BETONICA *Officinalis.*

*Common Officinal Wood Betony.*] Betonica with many oblong indented leaves on long foot-ſtalks from the root, and ſquare ſtalks a foot and half high, terminated by interrupted ſpikes of flowers.

*Varieties.*] Common Betony with purple flowers——with red flowers——with white flowers.

This ſort and varieties is a wild plant of our woods, much valued for its medical properties.

[2]BETONICA *Orientalis.*

*Oriental Betony*] Betonica with long, narrow, hairy, indented leaves, on long foot-ſtalks from the root, and ſquare leafy ſtalks a foot and half high, terminated by a large entire ſpike of purple flowers.

[3]BETONICA *Danica.*

*Large Daniſh Betony.*] Betonica with broad, heart-ſhaped, radical leaves; large upright ſtalks, ornamented with ſpear-ſhaped obtuſe leaves, and terminated by ſhort thick ſpikes of purple or white flowers.

All theſe are hardy plants, and will thrive in any ſituation.

They are propagated by ſeed and by parting the roots. Sow the ſeed in the ſpring, and the roots may be parted or tranſplanted either in the ſpring or autumn.

BETULA, the Birch-tree; comprehending alſo the *Alnus*, or Alder-tree.

This genus comprehends ſeveral ſpecies of hardy deciduous foreſt-trees, uſeful for purpoſes in gardening, and as underwood and timber-trees for many œconomical uſes.

Claſs and order, *Monoecia Tetrandria.*

The flowers are produced in a cylindrical amentum or catkin, with male and female flowers on ſeparate catkins, at a diſtance on the ſame tree; the male florets have four ſtamina, and the females two ſtyles, ſucceeded by ſingle ſeeds lodged in the ſcales of the amentum.

The ſpecies are,

[1]BETULA *Alba.*

*The White, or Common Engliſh Birch.*] Betula with an erect trunk covered with a white bark, riſing twenty or thirty feet high, dividing into many moderate branches, adorned with ſmall, oval, ſerrated leaves, ending in points.

[2]BETULA *Nigra.*

*Black Virginia Birch.*] Betula with a large upright trunk, and ſpreading ſpotted branches, growing fifty or ſixty feet high, garniſhed with larger, rhomboid-oval, doubly-ſerrated, pointed leaves, on long foot-ſtalks.

*Varieties.*] Broad-leaved Virginia Birch—Poplar-leaved Virginia Birch—Paper-Birch.

[3]BETULA *Lenta.*

*Canada Birch.*] Betula with an upright trunk and ſpreading branches, growing ſixty feet high; large, heart-ſhaped, oblong, pointed, ſerrated leaves.

*Varieties.*] Duſky Canada Birch—White-paper Canada Birch—Poplar-leaved Canada Birch.

[4]BETULA *Nana.*

*Dwarf Alpine Birch.*] Betula with a ſhrubby branching ſtem two or three feet high, garniſhed with round crenated-edged leaves.

The BETULA ALNUS, or Alder-tree, is,

[5]BETULA *Alnus.*

*Alnus, or Alder-tree.*] Betula with an upright ſtem, having purpliſh bark, riſing thirty or forty feet in height, dividing into many purpliſh erect-growing branches, adorned with

with large, round, glutinous leaves, of a deep green colour.

*Varieties.*] Common round leaved Engliſh Alder as above—Long-leaved American Alder—White Alder—Hoary-leaved Alder—Dwarf Alder.

All theſe ſpecies of *Betula* are extremely hardy, and will proſper upon almoſt any ſoil and expoſure, either in large pleaſure-grounds, parks, fields, &c.

For purpoſes in gardening, they, having ſtrait ſmooth ſtems, may be introduced for ornament and variety in extenſive grounds; their foliage will form an agreeable diverſity in aſſemblage with other deciduous trees, but their flowers poſſeſs little beauty; they have a good effect in large wilderneſs and wood-works, and in ornamental plantations on the boundaries of parks and conſiderable lawns; alſo in internal clumps in parks, and ſome planted ſingly as ſtandards in large opens.

The *Betula Alba*, or Common Birch, grows naturally in great plenty in many parts of Britain, proſpers in any ſoil, wet or dry, boggy, ſtony, or ſandy barren land, often ſowing itſelf, and comes up abundantly in ſuch places where hardly any other tree will grow; and in ſuch ground it may be cultivated to advantage, both as a foreſt-tree for its timber, and as coppice or underwood, to fall every ſeven or eight years for poles, &c.

The timber of this tree when old is eſteemed by the wheel-wrights, and turner's value it for many purpoſes; its lopping is excellent fuel, and the bruſh-wood make the beſt of brooms. See BROOMS.

The bark of theſe trees being of ſuch durable nature, that the Swedes cover their houſes with it.

Before the invention of writing-paper, the inner fine bark of this tree was often uſed for that purpoſe; hence ſome ſorts are called Paper-Birch.

A wholeſome wine is made of the juice or ſap of this tree, procured in March while the ſap is in motion, by boring holes in the body of large trees, and putting in faucets or taps of ſmall elder-pipes, to conduct the liquor into bottles, ſo that from a good many trees ſeveral gallons may be daily collected, without injuring the trees in their growth.

Coppices are formed of theſe trees in waſte barren land, to cut as underwood every ſix, eight, or ten years, for poles, for hoops, and many uſes in huſbandry; alſo for the bruſh-wood for birch-brooms, for which there is a conſtant demand. When ſuch coppices are intended, they ſhould be formed of young plants, previouſly raiſed in the nurſery; ſee their *Propagation*; from thence planted out at five or ſix feet diſtance, which in ſeven or eight years will be ready to cut, and will ſupport a cutting every ſixth year for the broom-men, and every eighth, tenth, or twelfth year, for poles for the hoop-benders and other uſes, and for huſbandry implements.

The two ſpecies of American Birch and varieties being equally hardy as the common ſort, but more ſwift in growth, and obtain a large ſtature, may alſo be introduced in woods and other plantations among foreſt trees.

The *Betula Alnus*, or Alder-tree, grows rapidly in marſhy watery places, or meadows contiguous to rivers, brooks, and other waters, in moſt parts of Britain, and is a uſeful tree both in its growing ſtate, and its wood as timber and for poles for various uſes, which growing freely in any moiſt or boggy ſoil, it may be cultivated to good account in any waſte, marſhy, or ſwampy grounds.

In its growing ſtate it is moſt uſeful to ſecure the banks of rivers, by planting truncheons pretty cloſe, which will grow and ſend up numerous ſuckers quite from the lower roots, which effectually prevents the banks from being undermined by the current.

Theſe trees are alſo uſeful to form hedges, to fence and divide boggy or ſwampy ground.

The wood of this tree is particularly valuable for works intended to be conſtantly under water, ſuch as water-pipes, ſluices, pumps, troughs, piles, &c. and the turners apply it to various uſes.

Coppices of theſe trees in boggy ground, to be cut as coppice or underwood every eight or ten years for poles, pay very well; theſe coppices may be formed of truncheons, i. e. large cuttings of three feet long, cut from growing trees, ſharpening one end, then making holes with an iron crow two feet deep and a yard aſunder, plant the truncheons two feet in the ground, they will readily grow and ſend up ſeveral ſtems, which in ſeven years will be large enough to fell for poles, at which time clear away entirely every other ſtool, ſo that the remainder ſtand five or ſix feet aſunder, and they will afford you a fall of good poles every eighth or tenth year.

But when intended to have theſe or any of the Birches ſtand for timber, they muſt be left fifteen feet aſunder.

*The Propagation of all the Species.*

The Birch-trees are propagated either by ſeeds or layers; the common ſort afford us plenty of ſeeds in autumn, but that of the foreign ſorts is imported by the ſeeds-men from America. Sow all the ſorts in beds of light earth in autumn or ſpring, covering it about half an inch deep, and the plants will come up in April or May, keeping them clean from weeds all ſummer; the ſpring following plant them out in nurſery-rows two feet and half aſunder, to remain till they are three, four, or five feet high, then tranſplant them where they are to remain.

By layers they may be raiſed plentifully from a few proper ſtools, having been previouſly headed down to the ground to produce lower branches, which when two years old will be well furniſhed with many ſide-ſhoots, which being ſplaſhed and layed in the ground, together with all their young twigs, every one of which will grow, and be fit to be planted out in the nurſery the following autumn, and the ſtools continue to furniſh a freſh ſupply of layers annually.

By this method of laying, all the varieties of the foreign kinds are continued, for they vary from ſeed.

The Alder-tree is alſo propagated plentifully by ſeed and layers as above; alſo by cuttings of any ſize, planted in any moiſt or ſhady place, will put out roots freely, and in two or three years will become large plants of three, four, or five feet ſtature, when they may be planted out for good.

Large cuttings or truncheons of two or three feet long may be planted at once by the ſides of rivers, brooks, &c. putting them two parts of three in the ground, they will grow, and afford a cutting for poles every ſeven or eight years.

BIENNIAL PLANTS; Plants, as the title *Biennial* imports, that are only of two years duration.

Numerous plants are of this tribe, which being raiſed one year from ſeed, generally attain perfection either the ſame, or in about the period of a twelvemonth, or a little leſs or more, and the following ſpring or ſummer ſhoot up ſtalks, flower, and perfect ſeeds, ſoon after which they commonly periſh, or if any particular ſort ſurvive another year, they aſſume a dwindling and ſtraggling growth, and gradually die off; ſo that Biennials are always in their prime the firſt or ſecond ſummer.

Biennials conſiſt both of eſculents and flower-plants.

Of the eſculent kinds, the cabbage, ſavoy, carrot, parſnep, beet, onion, leek, &c. are Biennials.

Of the flowery tribe, the Canterbury-bell, French honeyſuckle, wall-flower, ſtock-July-flower, ſweet-william, China-pink, common pink, matted pink, carnation, ſcabious, holly-hock, tree-mallow, vervain-mallow, tree-primroſe, honeſty or moonwort, &c. are all of the Biennial tribe; all of which being ſown in March, April, or May, riſe the ſame year, and in ſpring following ſhoot up into ſtalks, flower and perfect ſeeds in autumn, after which moſt of them dwindle, though ſometimes the wall-flowers, hollyhocks, carnations, pinks, will ſurvive and flower the following year, but the plants become ſtraggling, the flowers ſmall and badly coloured; it is therefore eligible to raiſe a ſupply annually from ſeed, although wall-flowers, carnations, and pinks, may be continued by ſlips and layers.

BIGNONIA, Trumpet-flower, or Scarlet Jaſmine.

The *Bignonias* are of the ſhrub and tree kind, comprehend many ſpecies, three or four of which are cultivated in our ſhrubberies, and conſiſt of climbing ſhrubs and an upright tree, garniſhed ſome with winged, others with ſimple leaves, and campanulate trumpet-ſhaped flowers.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX is monophyllous, cup-ſhaped, and quinquifid. COROLLA is one bell-ſhaped petal, having a long tube, ſwelling and five-parted at top, the two upper parts reflexed, the under ones ſpread open. STAMINA, two ſhort and two long filaments, and oblong reflexed antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and headed ſtigma. PERICARPIUM, a bivalvate pod of two cells, containing numerous winged ſeeds placed imbricatum.

The plants are moſtly of American growth; thoſe cultivated in our gardens are,

1 BIGNONIA *Radicans.*

*Radicant Climbing Aſh-leaved Scarlet Bignonia.*] Bignonia with climbing ſhrubby ſtalks, radicant or rooting at the points, mounting upon ſupport, thirty or forty feet high, ornamented with pinnated oppoſite leaves of four pair of ſmall ſawed lobes and an odd one, and all the ſhoots and branches terminated by beautiful cluſters of large trumpet-ſhaped ſcarlet flowers.

*Va-*

*Variety.*] Radicant leaſt Aſh-leaved Bignonia with ſmall flowers.

[2]BIGNONIA *Sempervirens.*

*Evergreen Climbing Virginia Bignonia.*] Bignonia with climbing ſlender ſtalks, twining upon, ſupport twenty or thirty feet high; ſimple lanceolate-leaves placed oppoſite, and trumpet-ſhaped, erect, yellow flowers, from the ſides and ends of the ſtalks and branches.

*Variety.*] Evergreen climbing four-leaved Virginia Bignonia.

[3]BIGNONIA *Catalpa.*

*Catalpa, or Tree Bignonia.*] Bignonia with an upright ſtrong woody ſtem and branches, riſing twenty feet high, ornamented with large heart-ſhaped leaves five or ſix inches long, almoſt as broad, placed by threes, and whitiſh yellow-ſtriped flowers in panicles towards the ends of the branches.

The flowers of all the ſpecies are monopetalous, tubular, long, and ſomewhat trumpet-ſhaped, (ſee the *Characters*), appearing moſtly in Auguſt, but rarely produce ſeed-pods in England.

As to their uſe in gardens, they are all employed as plants of ornament.

The firſt ſort and variety, if planted againſt high walls, will ſoon cover them, they emitting roots at all the joints of the ſtalks, which ſtrike into the joints of buildings, and mount to their tops if ever ſo high, where they will endure many years, and flower annually.

The ſecond ſort and variety being ſomewhat tender, muſt be planted againſt a warm wall, and ſheltered from froſt with mats while young.

The *Catalpa* is a very ornamental, hardy, deciduous ſhrub, or rather tree, worthy of a place in all curious ſhrubberies, as during the ſummer ſeaſon, when cloathed with its luxuriant beautiful foliage, no tree makes a more noble appearance, which, on account of its ſingular beauty, ſhould be placed conſpicuouſly, and ſome ſhould be diſpoſed ſingly upon ſpacious lawns, or other large opens of graſs-ground, and permitted to take their natural growth.

*Propagation of all the Species.*

The two firſt ſpecies and varieties may be propagated by layers; every ſhoot layed will readily grow, and will flower in two or three years.

Cuttings of the ſtrong ſhoots will alſo put out roots freely.

They may alſo be raiſed from ſeeds procured from America, ſowing them in pots in ſpring, and place them in a moderate hot-bed, from which the plants muſt be inured to the full air in ſummer, ſheltered in winter from froſt, and in ſpring plant them out in the full ground; but plants thus raiſed rarely flower in leſs than ſix or ſeven years.

The *Catalpa* may be propagated by cuttings of its young ſhoots, aided by artificial heat, planting them in pots in ſpring, which plunge either in a common dung hot-bed, or in a bark-bed; they will ſtrike in a month or ſix weeks, when they muſt be hardened to the open air, in which let them ſtand till October, then moved to a place of occaſional ſhelter from froſt, and in ſpring following plant them out in the nurſery.

This plant is alſo raiſed from ſeed, either in a warm border, or in pots, and plunged in a moderate hot-bed, which will facilitate the germination of the ſeed, which is ſometimes apt to remain a year before it begins to grow.

BIXA, Dying *Mitella*, Spaniſh *Anotta*, or French *Roucou.*

There is but one ſpecies, an evergreen ſhrub of the hot-houſe.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, a plane, obtuſe, permanent cup. COROLLA, ten large oblong petals in a double ſeries. STAMINA, numerous briſtly filaments. PISTILLUM, an oval germen, ſlender ſtyle, and parallely-bifid, compreſſed ſtigma. PERICARPIUM, an oval, heart-formed, hairy capſule of two valves and one cell.

The ſpecies is,

BIXA *Orellana.*

*American Bixa.*] Bixa with an upright ſtem ten feet high, branching out into a regular head, garniſhed with heart-ſhaped pointed leaves, placed alternate, and reddiſh flowers in panicles from the ends of the branches, ſucceeded by large, pulpy, red fruit; in great requeſt among dyers and painters.

This tender American ſhrub is retained here in ſtoves for variety.

It is propagated by ſeeds from America, ſown in pots in ſpring, and plunged in a bark-bed, and the plants are to be tranſplanted into ſeparate pots, and always retained in the ſtove.

BLIGHTS. Theſe are infectious diſtempers, which often attack our fruit-trees in ſpring and ſummer, frequently deſtroying the leaves, bloſſoms, and fruit, and ſometimes prove deſtructive to the trees themſelves.

Many

Many have attempted to account for the cauſes of Blights. Some ſuppoſe they proceed from ſome particular defect in the ſoil; others attribute the whole to the air, whilſt others are of opinion that it proceeds from the particular ſtate of the trees themſelves, eſpecially when they aſſume a weakly habit; ſome again aſcribe the diſtemper to eaſterly winds bringing vaſt quantities of inſect eggs from a diſtance, or that long dry eaſterly winds, unaccompanied by rain or night-dews, ſtop the perſpiration in tender bloſſoms, and occaſion them ſoon to wither and decay, and by long continuance of the ſame weather the leaves and tender ſhoots are alſo affected in like manner, and the perſpiring matter thickens to a glutinous conſiſtence, adhering to the ſurface, becomes nutriment to thoſe ſmall animalculæ which we often find ſo numerous on the leaves and young ſhoots of fruit-trees, diſcoverable by the ſhrivelling or curling of the leaves, and which, though not generally ſuppoſed to be the firſt cauſe of the diſtemper, yet they ſpread the miſchief conſiderably, as often, from a few twigs, they will over-run a whole tree, and ſpread themſelves to others on every ſide, to the deſtruction often of a whole wall of trees.

Againſt this annoyance to our fruit-trees there is no guard, nor any certain general method of cure after the trees are once conſiderably attacked.

Various methods however are practiſed to ſave wall and eſpalier-trees when the infection appears, ſuch as, when the diſtemper is ſlight, to pinch off all the worſt leaves, to prevent its ſpreading; alſo to cut off part, or even whole ſhoots, when moſt of the leaves on them, or the ſhoots themſelves, are infected, cutting them off below the diſtempered parts, and they will probably ſhoot out again the ſame or next year. After theſe operations frequently daſh the trees with water in a morning or evening, either out of a common watering-pot, or a hand-engine, the latter of which is the moſt effectual, which by a daily repetition for a week, will have a great effect in preventing the diſaſter from ſpreading, if not totally eradicate it, when not very formidable.

Some ſtrew tobacco duſt over the trees, or ſprinkle them with water in which tobacco-ſtalks have been infuſed.

There is a ſpecies of Blight called a fire-blaſt, the moſt certain and ſudden deſtruction to fruit-trees of any, as in a few hours it not only deſtroys the leaves and fruit, but frequently the branches, and ſometimes whole trees, and for which there is not the leaſt remedy.

A ſort of peſtilence ſometimes attacks wall-fruit trees, which cauſes the leaves and ſhoots to become black and clammy, generally terminating in the deſtruction of the tree, and will run through the whole walling, if not ſtopped by removing the diſtempered plant, and waſhing that part of the wall with lime or ſtrong brine.

BLITUM, Blite, or Strawberry-ſpinach.

The plants are herbaceous annuals of the ornamental kind, riſing with ſtems two or three feet high, garniſhed with ſpinach-ſhaped leaves, and cluſters of ſtrawberry-like fruit; hence the name Strawberry-ſpinach.

Claſs and order, *Monandria Digynia.*

*Characters.*] CALIX is tripartite, ſpreading, and permanent. COROLLA none STAMINA, one ſmall briſtly filament, and double antheræ. PISTILLUM, an oval, pointed germen, two ſtyles, and ſimple ſtigma. PERICARPIUM, a ſmall, oval, compreſſed capſule, having one globular compreſſed ſeed the ſize of the ſeed-veſſel.

The ſpecies are,

[1]BLITUM *Capitatum.*

*Capitated Strawberry-Spinach.*] Blitum with upright herbaceous ſtalks two feet and half high, garniſhed with triangular ſpinach-ſhaped leaves, and flowers in cluſtered heads at the joints and crown of the ſtalks, ſucceeded by red ſtrawberry-like fruit.

*Variety.*] Capitated White Strawberry-Spinach.

[2]BLITUM *Tartaricum.*

*Tartarian Strawberry-Spinach* ] Blitum with herbaceous ſtalks, riſing a yard high; triangular, acutely-indented, ſpinach-ſhaped leaves; and ſingle heads of flowers, growing only from the ſides of the ſtalks, ſucceeded by ſmall, red, ſtrawberry-like fruit.

[3]BLITUM *Virgatum.*

*Dwarf Virgate Strawberry-Spinach.*] Blitum with a ſlender ſtalk about a foot high; triangular, ſpinach-ſhaped, indented leaves; and heads of flowers growing ſparſedly all along the ſides of the ſtalk, ſucceeded by ſmall, reddiſh, ſtrawberry-fruit.

*Varieties.*] Dwarf Striped-leaved Strawberry-Spinach—Dwarf White Strawberry-Spinach.

All theſe ſpecies and varieties are hardy annuals, and riſe in ſpring firſt with a few leaves, ſhooting up ſtalks in May or June, flower and ripen fruit in July, Auguſt, and September, and ſoon after periſh.

They

They merit culture as plants of ornament, for the ſingular variety of their fruit, being the ſize of common wood-ſtrawberries, and numerous on the ſtalks, make a fine appearance in July and Auguſt, but are not eatable.

They ſucceed in the common borders, and ſome planted in pots to adorn court-yards, in aſſemblage with other potted plants, have a pretty effect.

Their propagation is by ſeed annually in March or April, ſown either in patches in the borders where they are to remain, or together in a bed of common earth, to be afterwards tranſplanted into the places where they are to flower, covering the ſeed about half an inch deep, and the plants will appear in a month, obſerving, if they are ſown in patches, to leave only three in a patch, at five or ſix inches diſtance, and if ſown in a bed for tranſplanting, they muſt be planted out before they begin to ſhoot up their ſtems, diſpoſing them as above in different parts of the borders; and if any are to be potted, plant one in each pot, giving the whole occaſional waterings.

When their ſtems are advanced, ſupport each with a ſtick, otherwiſe the weight of the berries will bear them down to the ground.

BOCCONIA, Greater Tree Celandine.

There is but one ſpecies, a ſhrubby exotic of the ſtove, eſteemed for the beauty of its large foliage.

Claſs and order, *Dodecandria Monogynia.*

*Characters.*] CALIX, two oval concave leaves. COROLLA, no petals. STAMINA, twelve ſhort filaments, and long antheræ. PISTILLUM, a large, roundiſh, contracted germen, ſemi-bifid ſtyle, and ſingle ſtigma. PERICARPIUM, an oval compreſſed fruit of one cell, full of pulp, and one ſeed.

The ſpecies is,

BOCCONIA *Fruteſcens.*

*Shrubby Bocconia, from Jamaica.*] Bocconia with an upright, ſtrait, robuſt, branching ſtem, growing ten or twelve feet high, covered with a white bark; large, deeply-ſinuated, glaucous leaves, ten or twelve inches long, half as broad, placed alternate; and flowers in looſe ſpikes from the ends of the branches.

The whole plant abounds with a yellow acrid juice.

This plant is propagated by ſeeds from America, ſowing them in ſpring in pots of light earth, and plunge them in a bark hot-bed; and when the plants come up, prick them into ſeparate pots, which muſt always be kept in the ſtove.

BOMBAX, the Silk-Cotton-tree; ſo called from the fine ſilky down contained in the ſeed veſſel.

There are three ſpecies, trees of extraordinary magnitude and lofty ſtature, natives of America, Aſia, and Africa, where, modern writers affirm, they are ſo large, that ſixteen men cannot fathom them, and ſo tall, that an arrow cannot reach their top, with heads ſo widely diffuſed (ſays Boſman in his Deſcription of Guinea) that 20,000 men, cloſely armed, might eaſily ſtand under the branches.

They are retained in this country in hot-houſes, as plants of ſingularity, and for the variety of their ſingular foliage; but there are little hopes of their ever flowering in England.

Claſs and order, *Monadelphia Polyandria.*

*Characters.*] CALIX is monophyllous, campanulate, quinquifid, and permanent. COROLLA is divided into five oval concave ſegments. STAMINA, many filaments united below, and incurved antheræ. PISTILLUM, a round germen, ſlender multiparted ſtyle, and round ſtigmas. PERRICARPIUM, a large, oblong, turbinated, ligneous, quinquivalvular capſule of five cells, full of a cottony down, incloſing many round ſeeds.

The ſpecies are,

[1]BOMBAX *Ceiba.*

*Ceiba, or Thorny Bombax.*] Bombax with an upright ſtrait trunk, cloſely armed with ſhort ſtrong ſpines, branches coming out near the top, adorned with leaves compoſed of five long ſpear-ſhaped lobes, connected at their baſe, and polyandrous flowers at the ends of the branches, ſucceeded by oval fruit larger than a ſwan's egg, filled with ſeeds and cotton.

[2]BOMBAX *Pentandrum.*

*Pentandrous Smooth Bombax.*] Bombax with an upright, ſtrait, unarmed trunk, branching at top, garniſhed with leaves compoſed of nine long ſpear-ſhaped lobes, united at their baſe, and pentandrous flowers from the end of the branches, ſucceeded by large oval fruit full of ſeeds and cotton.

[3]BOMBAX *Heptaphyllum.*

*Heptaphyllous Smooth Bombax.*] Bombax with an upright, ſtrait, unarmed trunk, branching near the top; heptaphyllous, or ſeven-lobed leaves, united at the baſe; and polyandrous flowers, ſucceeded by large oval fruit, containing ſeeds and cotton.

Theſe

Theſe trees being natives of both Indies, and other warm parts of the world, in this country muſt always reſide in a hot-houſe.

They are raiſed from ſeeds procured in the capſules from the Weſt Indies Sow the ſeeds in ſpring in pots of light earth, and plunge them in a ſubſtantial hot-bed of dung or tan, where the plants will appear in three or four weeks, which are to be pricked into ſeparate ſmall pots, plunging them in the bark-bed, giving ſhade and water, and let them be conſtantly kept in the ſtove, ſhifting them occaſionally into larger pots and freſh earth, watering them plentifully in ſummer, but moderately in winter.

BONTIA, Wild Olive of Barbadoes.

This genus comprizes one woody pyramidal evergreen of the ſtove, of ornamental appearance.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX, a ſmall quinquifid permanent cup. COROLLA, one ringent petal, with a long tube gaping above, the upper lip erect and emarginated, the under one trifid and revolute. STAMINA, four filaments, two longer than the others, and ſimple antheræ. PISTILLUM, an oval germen, ſimple ſtyle, and bifid ſtigma. PERICARPIUM, a large oval berry, including an oval nut.

The ſpecies is,

BONTIA *Daphnoides* ] Bontia with a woody ſtem and branches, riſing ten feet high; oblong, narrow, ſmooth, thickiſh leaves, crenated at the edges; and flowers from the ſides of the branches, ſucceeded by large oval fruit, that ſometimes ripen in England.

This plant is propagated eaſily by ſeeds in a hot-bed; alſo by cuttings, with the ſame aſſiſtance, and the plants muſt always remain in pots, and reſide in the hot-houſe.

BORAGO, Borage.

Of this genus are two hardy herbaceous plants, cultivated in our gardens, an annual and a perennial, riſing with ſtalks two feet high, ſimple leaves, and monopetalous flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is five-parted at top, and permanent. COROLLA, a ſingle rotated petal, with a ſhort tube, ſpreading and five-parted above. STAMINA, five connivent filaments, and oblong connivent antheræ. PISTILLUM, four germina, ſlender ſtyle, and ſingle ſtigma. PERICARPIUM none, the calix becomes ſwollen, and contains four roundiſh ſeeds.

The ſpecies are,

[1]BORAGO *Officinalis.*

*Common Annual Borage.*] Borago with annual roots, large, oblong, rough leaves, ſpreading on the ground; rough branching flower-ſtalks two feet high, garniſhed with leaves placed alternate, and flowers from the ſides and top of the ſtalk and branches

*Varieties.*] Common Borage with blue flowers—with red flowers—with white flowers—with variegated leaves.

[2]BORAGO *Orientalis,*

*Oriental, or Conſtantinople Perennial Borage.*] Borago with fleſhy ſpreading perennial roots, ſending up large heart-ſhaped leaves, and ſtalks two feet high, dividing upward into footſtalks, terminated by panicles of pale blue flowers.

The *Borago Officinalis* is the Common Annual Borage, an excellent pot-herb, and the young leaves and flowers are by many eſteemed to eat as a ſallad and for cool tankards, and the flowers alſo for medicine.

The plants riſe in ſpring, ſhoot up flower-ſtalks in May, June, and July, and continue flowering till autumn, when they perfect ſeeds, and then die.

They are propagated by ſeeds any time in ſpring, ſummer, or autumn, in any common ſoil, in the place where the plants are to remain, obſerving, when a conſtant ſucceſſion of the plants are required, it is proper to make three different ſowings from ſpring till autumn. Sow the ſeed broad-caſt, and rake it in, and when the plants have leaves an inch broad, clean and thin them by hoe to ſix or eight inches diſtance.

If this plant is permitted to ſtand to ripen and ſcatter its ſeeds, there will be a ſupply of plants at almoſt all ſeaſons of the year, which will continue riſing every time of ſtirring the ground.

The Oriental Borage is a perennial, and chiefly eſteemed as a flowering plant; it will proſper in any dry ſoil, and its propagation is either by ſeed, or dividing the roots in autumn.

BORDERS. In gardening, Borders are uſeful narrow compartments of ground, which divide and encompaſs the different principal diviſions of a garden, and bound the walks.

Borders may be conſidered of two kinds, the uſeful and ornamental.

For uſeful purpoſes, one ſort are thoſe which are carried round the walls of a kitchen-garden,

garden, and are moſt uſeful, whereon to plant various ſorts of dwarf fruit-trees, ſuch as peaches, nectarines, apricots, &c. to be trained to the wall to form wall-trees; and ſuch of thoſe borders that are of a ſouth aſpect, are likewiſe extremely uſeful, whereon to raiſe various early eſculent herbs, roots, and legumes; and thoſe of the other aſpects are proper for the raiſing and pricking out many ſorts of plants in ſummer, that require ſome degree of ſhade at particular periods of growth.

Theſe borders ſhould be a yard at leaſt wide, but if ſix or eight feet, the greater advantage it will be to the trees, &c.

Another ſort of uſeful Borders are thoſe which divide and ſurround the principal diviſion of the kitchen-garden, and immediately verge the main walks, which are uſeful, whereon to plant ranges of dwarf apple, pear, plum, medlar, and cherry-trees, &c. to form an eſpalier (ſee ESPALIER); for which purpoſe the borders ſhould be five feet broad, and the line of trees placed four feet from the outer edge thereof, ſo that there will be a four feet Border without, and a foot wide one within the eſpalier, both of which will be uſeful in the culture of many ſmall eſculent plants.

Borders in pleaſure-grounds are to be conſidered as of the ornamental kind.

In this diſtrict formerly Borders were very predominant; almoſt every walk was bounded on each ſide by a Border, embelliſhed with various ornamental plants: this taſte however is now almoſt ſupplanted; but a grand walk, ornamented on each ſide with a ſpacious border full of curious flowering plants, makes a noble appearance.

Likewiſe Borders for flowers, carried round the boundary of lawns near the habitation, have alſo an agreeable effect.

In the ancient taſte of parterre-works Borders greatly prevailed, the parterres being principally formed of numerous narrow Borders, with intervening alleys of the fineſt turf, gravel, ſhells, or ſand, the parterre being firſt bounded by regular borders, and within which were carried on the various geometrical works in many curious devices, but which is now baniſhed our gardens, like all other works of regularity: for the ſake of variety, ſome works of this nature might ſtill be admitted, particularly in the Chineſe taſte. See PARTERRES.

Borders for particular curious flowers, ſuch as the curious ſorts of hyacinths, tulips, ranunculas, anemones, carnations, &c. may be made either along the ſides of walks, or detached.

The proper breadth of Flower-borders is, that, if intended chiefly for ſmall plants, or for the different ſorts of bulbous-rooted flowers, they ſhould be four feet wide; but if deſigned for all ſorts promiſcuouſly, they ought to be ſix or eight feet in breadth.

Borders that immediately verge gravel or ſand-walks, ſhould be planted with edgings of dwarf evergreen plants; ſeveral ſorts are uſed, ſuch as box, thrift, pinks, &c. but the former is the neateſt and moſt durable edging yet known. See BUXUS.

The Borders ſhould always be raiſed two or three inches above the common level, and finiſhed off with a gentle ſwell or rounding.

BOSEA, *Yerva-Mora*, or Shrubby Golden-rod.

This genus furniſhes but one ſpecies, an exotic ſhrub of the green-houſe.

Claſs and order, *Pentandria Digynia*.

*Characters.*] CALIX is five roundiſh concave leaves. COROLLA, no petals. STAMINA, five filaments and ſimple antheræ. PISTILLUM, an oval oblong germen, no ſtyle, but two ſtigmas. PERICARPIUM, a globular berry, having one ſeed.

The ſpecies is,

BOSEA *Yerva-Mora*.

*Yerva-Mora, or Golden-rod-tree.*] Boſea with a ſtrong woody ſtem, dividing irregularly into branches, grows eight or ten feet high, garniſhed with long leaves, whitiſh underneath, with purple veins, and purple flowers in cluſters from the ends of the branches.

It is an exotic from the Canary iſlands, and is retained here, to add to the collection of the green-houſe.

Its propagation is by cuttings planted in pots in ſpring; and, if plunged in a hot-bed, will more quickly emit roots, though they often effect it without that aid.

BOSQUETS are clumps, or detached compartments of ornamental trees, ſhrubs, and plants, diſpoſed either in a regular or irregular form, to embelliſh gardens, parks, &c.

Theſe compartments have a very ornamental effect in gardens, and are compoſed of a great variety of deciduous and evergreen trees, and herbaceous perennials of tall growth. Their dimenſions ſhould be proportioned to the extent of the ground, even from ten to a hundred feet, or more, in width, though the

ſize and form ſhould be varied in different expoſures; and as to figure, ſome may be planned in different regular forms, others in ſeveral different irregular figures, to effect the greater diverſity; but in ancient deſigns, they were generally all diſpoſed in regular ſquares, angles, circles, octagons, &c. and commonly each ſeparate Boſquet was bounded by regular hedges, kept low, and in exact order, by an annual ſhearing, having grand entrances formed into porticos, and other architectural devices; and within the hedges of the large compartments, walks of graſs, gravel, or ſand, were often carried round, and between the trees; but I ſhould not adviſe any general work of ſurrounding theſe compartments with hedges, for the trees and other plants will appear to greater advantage in open rural clumps, although, for the ſake of variety, a regular Boſquet, ſurrounded as above, might be here and there admitted in ſpacious gardens; but the hedges ſhould not be permitted to be more than four feet high, and may be either of evergreen, or deciduous plants: of evergreens, ſuch as yews, holly, lauruſtinus, laurel, alaternus, phillyrea, evergreen-oak, tree-box, bay; and of deciduous kinds, hornbeam, beech, elm, lime, alder; all of which ſhould be neatly ſheared annually, and kept ſo low that the trees and plants within may be eaſily ſeen from the outer walks, lawns, &c. See HEDGES.

The diſpoſition of theſe compartments, both of the regular and irregular deſigns, ſhould be ſo varied as to produce the greateſt diverſity; ſome placed towards the boundaries of grand lawns and ſpacious opens, others in forming ſhrubberies, wilderneſs-works, &c. and ſome natural clumps may be ſtationed on the boundaries of rural avenues; alſo diſtributed in different parts of parks.

In planting and embelliſhing theſe compartments, great variety of ſhrubs and trees ſhould be employed, both evergreen and deciduous, of different magnitudes, ſhades, and times of flowering, and particular care is neceſſary to diſpoſe the trees and ſhrubs according to their ſeveral growths and ſtatures, ſo as they riſe gradually one above another from the ſides to the middle, and at ſuch proportionable diſtances, that there may be full ſcope for the rural diffuſion of branches, ſo as each ſort may diſplay its ſpreading head according to its natural growth.

It is moſt adviſeable to plant the deciduous plants and evergreens in ſeparate clumps, though a few dwarf evergreens may be diſtributed in the fronts of the deciduous compartments; and in the clumps of both ſorts may be planted alſo, towards the ſides, various kinds of tall perennials, and near the edges low plants of primroſes, polyanthus, violets, daffodils, &c.

All the culture neceſſary to the various plants in theſe compartments, is to cut out any dead wood, and retrench or ſhorten very irregular branches, juſt to preſerve them within moderate bounds, and each ſort diſtinct; and the ground between the plants to be annually dug, eſpecially in ſmall Boſquets, and hoed two or three times in ſummer to deſtroy weeds.

BOWLING-GREEN, a ſpacious level graſs-plat in pleaſure-grounds, deſigned both for ornament, and the recreation of bowling in ſummer.

This compartment is generally planned near the habitation, contiguous to the back or ſide-fronts, ſometimes ſerving alſo by way of a lawn to that part; or it may be ſtationed at the termination of a grand walk or avenue of moderate extent, for it ſhould not be far from the houſe; or it might be contrived amidſt any contiguous detached plantation, or wilderneſs-work, ſerving alſo by way of a grand opening to ſuch places, and ſhould at any rate have the advantage of the ſhade of tall trees, ſo ſtationed on the boundary as to afford ſhade, which, at leaſt, ſhould be pretty conſiderable in an afternoon, as that being the time of day company uſually walk out to the diverſion of bowling.

As to the dimenſions, that where there is ſcope of ground, ſhould not be leſs than an acre; and as to figure, the moſt common is that of an exact ſquare; but ſome are alſo oblong, others are circular, though, to ſuit the general plan or figure of the ground, it may be contrived either of a regular form, or any well-calculated irregular deſign, when conſiſtent with the other works of the garden; and its boundaries may be a ſpacious border, either ſtrait or ſerpentine, embelliſhed with the choiceſt ſhrubs and flowers, although, in the ancient regular works, the boundary was very commonly a regular graſs-ſlope of two or three feet perpendicular height, ſometimes forming a ſort of terraſs round, with a gravel-walk at top.

The plane or ſurface of the Green ſhould be of a horizontal level, and as high at leaſt as the general level of the adjoining ground, ſo as to preſerve it always free from ſtanding water.

It ſhould be levelled in an exact manner, and layed with the fineſt graſs-turf that can be procured from a cloſe-paſtured common or downs. See TURF.

The dimenſions ſhould be ſet out with ſtakes placed round the extremity fifteen feet aſunder, then take the determined level by five ſtakes, that is, one in the middle levelled to the determined height, and according to this, level in four more, one on each ſide of the ground, as directed under the article LEVELLING, ſo that there will be five ſtakes in two lines ſet in a true level; then place ſtakes in rows croſs-ways at fifteen feet diſtance, to form the ground into pannels, for the greater convenience of levelling it to truth, obſerving to level in theſe according to the above five ſtakes; and when this is done, proceed by line and ſpade to form the ground, by making up lines firmly from ſtake to ſtake according to the mark of level, and ſo make up and rake the pannels according to the lines, working every part equally firm, that it may not hereafter ſink into hollows; and if the ſurface has two or three inches depth of light, ſandy, or any poor dry earth, it will render the graſs finer.

The turf for laying the Green is to be cut in the uſual way a foot wide, a yard long, and an inch thick, which muſt be laid with the greateſt exactneſs, well-beating and rolling it repeatedly, as directed under the article GRASS.

To keep the Green in perfect order, it muſt be conſtantly poled and rolled once or twice a week, or oftener, as you ſhall ſee it neceſſary; for as often as worm-caſts appear it muſt be poled, to ſcatter them about, then directly rolled with a wooden roller, to which the ſcattered worm-caſts readily adhere, whereby the ſurface is rendered clean; it muſt alſo be frequently rolled with a heavy roller, to preſerve a firm and even ſurface; mowing muſt alſo be duly performed in the proper ſeaſon once a week at leaſt, but if much played upon, it will require mowing two or three times a week at ſome particular times, eſpecially where the graſs abounds with common wild daiſies.

All weeds that appear ſhould be carefully picked out, otherwiſe they will encreaſe, and greatly deface the graſs.

BRACTEA, a Floral Leaf, the botanic term for ſuch leaves that are attendant on the flower, coming out with it on the ſame ſtalk, differing in ſize, ſhape, and colour, from the other leaves of the plant, and are often ſituated ſo near the flower as to be ſometimes miſtaken for the calix.

BRACTEA is alſo one of the ſeven fulcra, or props of plants. See FULCRA.

BRASSICA, the Cabbage, Cauliflower, Broccoli, &c.

This genus is very comprehenſive in uſeful eſculents of the kitchen-garden; it includes not only the numerous tribe of cabbages, ſavoys, borecole, and coleworts, but alſo the cauliflower, and all the varieties of broccoli, and, according to Linnæus, alſo the turnep; but to render every thing as intelligible as poſſible for practice in their cultivation, we ſhall treat of each article in a ſeparate diviſion, under the generic head Braſſica.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, four ſpear-ſhaped, concave, deciduous leaves. COROLLA, four oval plane petals placed croſs-ways. STAMINA, four long, and two ſhort filaments, and erect pointed antheræ. PISTILLUM, a taper germen, ſhort ſtyle, and headed ſtigma. PERICARPIUM, a long depreſſed pod of two cells, filled with round ſeeds.

Modern botaniſts contend, that there is only one real ſpecies of cabbage, and that the original ſpecies is the wild perennial ſea-cabbage, and the parent of all the different cultivated varieties of cabbage, ſavoys, borecole, coleworts, turnep-cabbage, cauliflower, and broccoli. Whatever the five former ſorts may be, the cauliflower is apparently a diſtinct ſpecies of the ſame genus, and the broccoli is moſt probably a variety of the cauliflower.

The original ſpecies, according to modern botaniſts, is,

BRASSICA *Sylveſtris.*

*Wild Perennial Sea-Cabbage.*] Braſſica with a perennial root and ſtalk, the ſtalk dividing into many perennial branches, garniſhed with cut leaves, placed alternate, and a cluſter of leaves, terminating all the ſhoots and branches.

It grows wild on Dover-Cliffs and other ſea-coaſts, and if required in gardens for curioſity, it may be raiſed from ſeed like other cabbages.

From this wild cabbage, ſay modern botaniſts, were obtained all the following cultivated varieties of our gardens.

[1]BRASSICA *Capitata*, Common Heading Cabbage, including a large train of varieties.

[2]BRASSICA *Capitata Saubada*, Savoy Cabbage, or Savoy, including varieties.

[3]BRASSICA *Fimbriata*, Fringed Cole, or

Borecole, including Scotch-Cole, and moſt other varieties of open Colewort.

[4]BRASSICA *Caulo-rapa*, Turnep-Cabbage.

[5]BRASSICA *Cauliflora*, the Cauliflower.

[6]BRASSICA *Broccoli*, the Broccoli, including varieties.

The following is undoubtedly a diſtinct ſpecies, which although, in its general habit, is apparently a very different plant from the cabbage-kind, yet the characters of its flowers being the ſame, Linnæus ranges it as a ſpecies of *Braſſica*.

[7]BRASSICA *Rapa*, RAPA, or the Turnep.

As the above articles are commonly conſidered as different plants among gardeners, and moſtly requiring different culture, we ſhall treat of them, and their reſpective varieties, under ſeparate heads; and firſt of the Common Cabbage.

*Firſt Diviſion.*

[1]BRASSICA *Capitata*, Common Heading Cabbage, and varieties.

The varieties of this ſort are numerous, and are all denominated Cabbages, from the circumſtance of their inner leaves turning in cloſely one over another, till by degrees they form a large, compact, globular, or oval head, ſome varieties of which obtain an enormous magnitude, and ſometimes weigh fifty or ſixty pounds.

As ſome varieties are in perfection in ſummer, others late in autumn, they are divided into different claſſes, viz. 1. Summer Cabbages, 2. Autumn Cabbages.

The Summer Cabbages are,

[1]*Early Summer Cabbage.*] *Varieties*, Small roundiſh early Cabbage—Larger oblong early Cabbage.—The firſt ſort comes early in May, the ſecond about the middle, or towards the latter-end; both of which ſoon become very hard and crack, ſo there ſhould not be any conſiderable quantity raiſed for private ſervice.

[2]*Sugar-loaf Cabbage.*] *Varieties*, Early Dwarf Sugar-loaf Cabbage—Large Hollow Sugar-loaf Cabbage.—The firſt is a ſmall, longiſh, pyramidal Cabbage, comes early in June, and is very ſweet while young, but ſoon grows hard; the ſecond is a fine, large, pyramidal, hollow Cabbage, comes the end of June, and is in fine perfection in July and Auguſt, ſeldom grows hard or cracks, and is a fine family or marketable Cabbage.

[3]*Ruſſia Cabbage.*] A ſmall roundiſh Cabbage, comes in July, heads very faſt, and ſoon grows hard; but if uſed while young and hollow is very ſweet and tender.

The following are autumn and winter cabbages.

[4]*Common Round White Cabbage.*] A middle-ſize, roundiſh, very white Cabbage; is in perfection in Auguſt and September, gradually acquires a degree of hardneſs, and is hardy to endure the winter.

[5]*Long-ſided Cabbage.*] A large, long, ſomewhat hollow Cabbage, comes in for uſe in September, and continues excellent all October and November, and ſeldom grows very hard.

[6]*Hollow Cabbage.*] A very large oval hollow Cabbage, never grows hard, is exceeding ſweet and tender eating, and is in high perfection in September and October.

[7]*Flat-top'd Cabbage.*] A very large ſpreading Cabbage, generally cabbaging very broad, and flat at top, and pretty cloſe and firm, is in perfection in September, and will continue till Chriſtmas.

[8]*Muſk Cabbage* ] A middle-ſize, roundiſh, hollow, very tender, criſp-eating Cabbage, of a muſky ſcent; is in perfection from September till Chriſtmas.

[9]*Giant, or Great Scotch Cabbage.*] An admirable, large, roundiſh Cabbage, heading very cloſe and hard, arrives to perfection in September and October, and will continue all winter; valued principally as a Field-cabbage for feeding cattle.

[10]*Red Cabbage.*] A middle-ſize, roundiſh, thick-leaved Cabbage, heading very hard, the whole as red as blood, and the darker the red, and the more thick and fleſhy the leaves, without any white in the ribs and veins, the more valuable; is in perfection from autumn until the end of winter, eſteemed chiefly as a choice pickle, alſo to ſhred raw to eat as a ſallad.

All theſe varieties of Cabbage are of the biennial tribe, being raiſed and attain perfection one year, the next they ſhoot up into ſtalk for flower and ſeed, and ſoon after totally periſh.

They are all raiſed from ſeed annually in beds of common earth, from which they muſt be tranſplanted; the time for ſowing is autumn and ſpring; thoſe raiſed in autumn arrive to perfection early the following ſummer and autumn, and the ſpring-ſowings cabbage the ſame year, but not till autumn and beginning of winter, and ſeldom in ſuch perfection as the autumn-raiſed plants. See their Culture.

*Culture of the Summer Kinds.*

The early Summer Cabbage, the Sugar-loaf Cabbage, and Ruſſia Cabbage, are generally cultivated for ſummer ſervice, and

may

may either be ſown in ſpring or autumn; but by raiſing the plants in autumn, i. e. Auguſt, they arrive to perfection early the following ſummer, that is, ſome of which are planted out in October or November, the others in the ſpring; the early kinds attain perfection in May, which will be ſucceeded by the Sugar-loaf and Ruſſia Cabbage in June and July, furniſhing a ſupply till autumn, when theſe will be ſucceeded by the ſpring-raiſed plants, either of the ſame, or large late ſorts; but the large Sugar-loaf Cabbage is what I ſhould chuſe to cultivate principally for the general ſummer crop, particularly for ſupply of a family, being the fineſt eating Cabbage, and continues the longeſt in perfection; though for market-uſe they often raiſe a larger quantity of thoſe that take up the leaſt room, and come in and out the ſooneſt; for the early kinds cabbage very faſt, ſoon grow hard, and do not continue good above a month.

Therefore, in order to raiſe an early and general ſummer crop of any, or all of theſe ſorts, let ſome good freſh ſeed be procured for ſowing the firſt or ſecond week in Auguſt; mark the time, for if ſown earlier, the plants are apt to fly up to ſeed in ſpring, and if ſowed much later, they will not acquire due ſtrength before winter.

At that time prepare a ſpot of rich ground in an open expoſure, digging it neatly one ſpade deep, and divide it into one or more four feet wide beds; directly ſow the ſeed, each ſort ſeparate, and immediately tread and rake it in. If the ſeaſon proves ſhowery, the plants will riſe in ten or twelve days; but if dry weather prevails, it is neceſſary to water the beds frequently both before and after the plants appear, and keep them clean from weeds.

About the middle of September, or when the plants have leaves an inch or two broad, it is proper to prick out a quantity of the largeſt from the ſeed-bed into nurſery-beds, to acquire due ſtrength previous to their being planted out for good in October and ſpring. For this purpoſe of pricking out, dig an open ſpot of the beſt ground, divide it into four feet wide beds, and rake the ſurface ſmooth; here prick the plants in rows ſix inches diſtance, and three or four inches apart in the lines, giving directly a hearty watering, which, if dry weather ſucceed, ſhould be repeated occaſionally.

Here they are to remain, ſome till October or November, and the principal part till February or March, at each of which times a quantity of the ſtouteſt plants are to be tranſplanted for good into the places where they are finally to remain to cabbage; good ground in an open expoſure muſt be allowed them, and if this is well dunged, it will be a particular advantage to the crop, digging in the dung one ſpade deep; then by line and dibble proceed to put in the plants in rows, the ſmall early kinds two feet row from row, and about the ſame diſtance in the lines; but the large Sugar-loaf kinds ſhould be ſet two feet and half diſtance every way, and a double quantity of theſe ſorts ſhould alſo be planted, if for the ſervice of a family, for the early kinds ſeldom continue long before they grow hard. Thoſe of each ſort that are planted in autumn will come in for uſe the earlieſt; and the ſpring plantation will ſucceed them regularly. Obſerve that, as the autumn plantation ſometimes ſuffers by the ſeverity of froſt, or other cauſes, in winter, when this is the caſe, the deficiencies muſt be made good occaſionally from thoſe in the nurſery-beds.

Thoſe plants that have remained in the nurſery-beds all winter, ſhould be planted out finally in February, though, if they are much cut by the winter's froſt, it is proper to let them remain until March or April to recover, planting them as above directed.

When the winter happens to prove ſo ſevere as to cut off moſt of the autumn-raiſed plants, recourſe muſt be had to an early ſpring ſowing in February, or early in March, but the ſooner the better.

But where a conſtant ſucceſſion of perfectly young Cabbages are required to be continued through the ſummer and autumn ſeaſons, it is eligible to perform a ſpring and ſummer ſowing, to ſucceed thoſe of the autumn raiſing; therefore ſow ſome of the Sugar-loaf kind in February or March, and more about the middle of May, managing them as already directed, which will furniſh a ſupply of young Cabbages from Auguſt till December.

All the culture theſe crops require after being finally planted out, is to hoe the ground occaſionally between them in dry weather, to deſtroy weeds, and when the plants have advanced a little in growth, to draw ſome earth once or twice about the bottom of their ſtems, which will ſtrengthen the plants, and forward them conſiderably, that probably the earlieſt ſorts will make an effort for heading early in May, when, if you are anxious to have them as forward as poſſible, ſome of the beſt

beſt may be aſſiſted, by tying their leaves regular together with an oſier-twig, or piece of baſs, which will blanch them internally, make them criſp and ready for the table eight or ten days ſooner. When the early kinds are cut for uſe, permit the ſtalks to remain to produce a crop of ſprouts, which they will effect abundantly; and theſe may either be gathered while young and green, or ſome might ſtand to form little heads, either of which are in many families preferred to any other ſummer greens; for which purpoſe, therefore, of yielding ſprouts, a quantity of the Sugar-loaf Cabbage-ſtalks ſhould be particularly left all ſummer and autumn.

*Culture of the Autumn Kinds.*

As already noticed, the autumn and winter Cabbages are, the Common Round White Cabbage—Long-ſided Cabbage——Hollow Cabbage—Flat-topped Cabbage—Muſk Cabbage—Giant or Scotch Cabbage—and the Red Cabbage.

Theſe ſorts are adapted principally for autumn and winter uſe, as they rarely attain tolerable perfection before Auguſt, and ſome of the larger kinds not till September and October, and continue in excellent condition till Chriſtmas, or ſometimes till the end of winter, ſome of which arrive at an enormous bulk, and if uſed while young, that is before they grow hard, are excellent eating.

The ſeaſon for ſowing all theſe late kinds is either in autumn or ſpring, but to have a large ſucceſſion, it is proper to ſow ſome at both ſeaſons; thoſe ſowed in autumn, i. e. the firſt week in Auguſt, arrive at perfection betimes the following Autumn, that is, Auguſt and September; and the ſpring ſowing come in about Michaelmas, though they ſeldom attain any tolerable perfection till the end of October, and are very fine in November and December, but rarely obtain ſo large a growth as the autumn-raiſed plants.

As before obſerved, the autumn ſowing is to be performed in the beginning of Auguſt, and the ſpring ſowing in March, or early in April.

The ſame method of ſowing the ſeed, and pricking out the plants, is to be obſerved, as directed for the ſummer kinds; and the time for tranſplanting them finally is, for the autumn-raiſed plants, a few in October, but the principal part in February, or early in March, and the ſpring-raiſed plants will be ready to plant out in May or June; all of which muſt have an open expoſure, well-dunged ground, and the plants ſet in rows two feet and half at leaſt diſtance; but for the larger kinds, a yard diſtance each way ſhould be allowed. All the culture they need is hoeing, to extirpate weeds, and drawing earth about their ſtems, which is an eſſential piece of culture to all the Cabbage kind.

The Red Cabbage is valued principally for pickling and ſtewing, and is in perfection in autumn and winter; it requires exactly the ſame culture as the former ſorts. The ſeed may be ſown in autumn or ſpring, though, as being a late Cabbage, the ſpring-raiſed plants rarely attain any tolerable ſize, therefore it is proper to ſow the main crop early in Auguſt, and the plants will be fit to prick out in September or October in nurſery-beds, to remain till February or March; then plant them out finally into an open ſituation, where they will arrive at due perfection about Michaelmas, and continue ſeveral months.

*Cabbage Coleworts.*

Cabbage Coleworts are now almoſt univerſally ſubſtituted in lieu of the common open green Colewort, which, though of eſtimation on account of its hardineſs, in being proof againſt froſt, yet, as table-greens, are apt to be tough and rank-taſted, and greatly inferior to the former. What was originally underſtood by Coleworts, is ſuch Cabbage-greens that never cloſe or cabbage, but always remain quite open and green to the heart, ſo were formerly raiſed in autumn and winter as open greens; and that by uſing Cabbage-plants as ſuch while they continue open and green, are now denominated coleworts, which are the moſt excellently ſweet and tender greens that can be cultivated for autumn and winter eating, and continue exceeding fine all the ſpring, and ſupply the table till the arrival of ſummer Cabbages; ſo that for ſupply of a family, a conſiderable quantity ſhould always be raiſed every autumn.

Any ſort of white Cabbages may be ſown for this purpoſe of Coleworts, though the Sugar-loaf kind ſurpaſſes all the other ſorts for delicacy of eating.

The proper time for ſowing the ſeed of either kind, for the purpoſe of Coleworts, is any time in July, for the autumn and winter crop; but to have them continued without running for ſpring drawing, ſome ſeed ſhould alſo be ſowed the beginning or middle of Auguſt, as obſerved of the Cabbages.

They

They are to be ſown in an open ſpot, and raked in, and when the plants have leaves two or three inches broad, tranſplant them where they are finally to ſtand, in rows a foot aſunder, and half that diſtance in the rows; all the culture they require is to have the ground hoed, to kill weeds, and looſen it about the plants; and when their leaves are as large as a man's hand, or thereabout, they are of due ſize to begin to draw as Coleworts.

In drawing the Coleworts for uſe, eſpecially the ſpring crop, where there is a large quantity, ſome draw every other row, permitting the intermediate ones to ſtand to cabbage, ſo cutting for uſe alſo every other one in the remaining rows, according as they form little hearts, leaving the others to cabbage more perfectly.

*Saving Cabbage-Seed.*

The common method to ſave Cabbage-ſeed, is to plant ſome of the full-grown Cabbages in autumn or beginning of winter in a dry ſpot, trenching them in down to their heads at two feet diſtance each way; or otherwiſe, either let a quantity of the ſtalks, after the heads have been cut occaſionally for uſe, remain, or tranſplant them to a convenient ſpot, to produce ſeed from their ſprouts, which anſwers the ſame purpoſe, but in this caſe no ſprouts muſt be gathered from theſe ſtalks; or inſtead of either of theſe methods, particularly to the ſummer Cabbages, you may ſlip a quantity of the forwardeſt ſprouts from the ſtalks in June, July, or early in Auguſt, in moiſt weather, and plant them twelve or fifteen inches diſtance, giving occaſional watering, they will readily take root.

In either of the above methods, the plants will all ſhoot up to ſtalk the following ſpring, flower in June, and perfect ſeeds in July or Auguſt.

It is neceſſary here to remark, that, in order to preſerve the reſpective varieties genuine, the moſt perfect of each ſort ſhould be marked when in full perfection, for without this precaution they will degenerate. Another thing of importance is, that if it is intended to ſave ſeed from more than one ſort, the different varieties ſhould be planted as far diſtant from one another as the extent of the garden will admit, to prevent as much as poſſible the communication of the farina of the different ſorts, which would fecundate each other, and the effect would be productive of a mongrel breed.

When the ſeed begins to ripen, watch the birds, which will attack it voraciouſly from every quarter.

As ſoon as it is fully ripe, which is very diſcoverable, cut the ſtalks off near the bottom, and after being expoſed a few days in the ſun to dry, let the ſeed be threſhed out upon cloaths, or a cloſe even floor, and ſpread it in a dry airy place a day or two to harden, then put it up in bags.

*Second Diviſion.*

[2]BRASSICA *Saubada*, the Savoy-Cabbage, or Savoy.

The Savoy is a variety of the Cabbage, though with care it will always retain its difference from ſeed; it admits of ſome varieties, all of which have finely curled leaves, and they head or cabbage to a large ſize, which are fine eating from Auguſt till March.

*The varieties are*] Common Green Savoy—Large Green Dutch Savoy—Yellow Savoy.

Theſe varieties are excellent for autumn and winter ſervice; they cabbage to fine handſome heads, which never grow hard nor crack, greatly excelling any other ſort of headed Cabbages for winter eating; and as they endure the froſt better, they are moſt profitable both for family uſe and the ſupply of markets during winter.

They are propagated by ſeeds ſown at two or three different times, that is, if intended to have Savoys as early as poſſible, it is proper to perform the firſt ſowing in Auguſt, as directed for the common Cabbages, or early in February, and another ſowing in March, and a third about the middle of April, by which practice you will have a fine ſucceſſion of large heads from about the middle of Auguſt to the end of winter; thoſe of the autumn-raiſed plants will be exceeding large, and in fine order for eating part of Auguſt, all September and October, which will be ſucceeded by the others in October and November, and which will continue through the winter, and part of the ſpring, till they run up for ſeed.

Each ſowing ſhould be in an open ſpot, and raked in, and when the plants have leaves an inch or two broad, and that, if they ſtand thick in the ſeed bed, it is proper to prick out a quantity of them three or four inches diſtance, to acquire ſtrength againſt the time for planting them out finally. Some of the autumn-raiſed plants may be planted out for good in October or November, or any time in winter, or beginning of ſpring; and the ſpring-raiſed plants are to be planted out occaſionally as ground is cleared, any time in May,

May, June, July, and Auguſt; thoſe planted out early ſhould be ſet two feet and half diſtance every way, and the next crop about two feet; but the latter plantations need not be planted more than a foot and half diſtance; all of which plantations ſhould be in open expoſures, the farther from trees, hedges, buildings, and the corners of gardens, the better, as the leſs liable they will be to the depredations of caterpillars, as is the caſe frequently with thoſe in cloſe ſituations.

It is cuſtomary to plant out the ſummer plantations of theſe plants between rows of forward beans, peas, kidney-beans, cauliflowers, early cabbage, and other crops that ſtand diſtant in rows, and are ſoon to come off the ground; by this practice ſome time is gained, though the plants are generally fineſt in the end, when they are planted in a clear ſpot of ground, previouſly dug for their reception.

In performing the ſummer plantations, it is of much advantage to chuſe moiſt weather for that work, otherwiſe watering muſt be practiſed ſeveral times till the plants ſtrike root.

All the culture they require, is to be hoed to kill weeds, and draw a little earth up to their ſtems.

To ſave Savoy-ſeed you may either plant down a quantity of the beſt ſorts in winter, or beginning of ſpring, or permit the ſtalks to ſtand, or tranſplant them to a convenient place to produce ſeed from their ſprouts, as obſerved of the common cabbage, which ſee.

*Third Diviſion.*

[3]BRASSICA *Fimbriata*, Fringed Cabbage, or Borecole, Scotch-Cole, and Common Coleworts.

The Borecole, and the other plants of this claſs, are all varieties of Cabbage of the open kind, or ſuch that never cloſe to form a head or cabbage, but always remain quite open and looſe to the heart, all of which poſſeſs ſuch a degree of hardneſs, as to bid defiance to the ſevereſt winter weather; ſo a few of them merits culture, to ſtand as reſerve in caſe of a ſevere winter cutting off the other greens.

*The varieties of Borecole are*] Green Curled Borecole——Red Curled Borecole—Thick-leaved Curled Borecole—Finely-fringed Borecole.

All theſe varieties of Borecole generally riſe with thick ſtalks a yard or more high, ſurmounted by a large head of thick leaves, ſpreading horizontally every way, which are finely fringed, and curled in a curious manner; and in the ſpring the ſides of the ſtalks are cloſely adorned from bottom to top with fine ſprouts, which, as well as the principal head, boil exceeding green, ſweet, and tender; and as they are extremely hardy, I ſhould adviſe, for the ſervice of a family, to cultivate a due quantity every year, to ſtand till towards ſpring, by way of reſerve, in caſe of a ſevere winter.

They are raiſed from ſeeds ſown in March, or beginning of April, in an open bed of good earth; the plants will riſe in a fortnight, or leſs time, a quantity of which ſhould in April, or beginning of May, be pricked out four or five inches aſunder, to remain ſix weeks; then plant them out finally into a fully open expoſure, in rows two feet diſtance.

Thoſe raiſed in March, and planted out early in ſummer, will advance with fine tall ſtems and large heads, and the advantage of their high ſtems is, they furniſh the greater ſupply of ſprouts, which come out cloſely on every ſide from the very bottom to the top.

To have good ſeed, mark ſome of the fineſt ſorts in winter, and let them remain entire; they will run up in the ſpring, and ripen plenty of ſeeds in autumn.

*Scotch-Cole, or Kale.*

The Scotch Cole is alſo an open Colewort, and ſort of brown Borecole, but ſome ſorts have more robuſt ſtems, larger heads, with large, broad, curly leaves, in ſome ſtanding erect, ſometimes contracting themſelves a little inward, but never cabbage. Of this ſort, however, there are ſeveral varieties, ſome red, ſome green, &c. and are fine eating in winter, requiring the ſame culture as the Borecole.

Of this kind are perennial varieties, with variegated leaves, preſerved in gardens as plants of ornament.

There are likewiſe perennial ſhrubby kinds of this ſort, riſing with tall branchy ſtems, adorned all the year with leaves, which in ſome ſorts are finely variegated, and are of many years duration; thoſe of them having variegated leaves make a pretty appearance.

All the ſorts are raiſed from ſeed; but the variegated kinds are continued by planting ſlips of them in ſpring.

*Common Green Colewort.*

This is a hardy, open, green plant, hath large plane leaves, generally always green, will

will grow large, but never contracts, or forms any head, like a cabbage, is a very hardy plant, and was formerly cultivated in every garden for winter greens, and is the original garden Colewort; but till ſeverely pinched by froſt, it is tough and rank-taſted, and, at any rate, never boils ſo fine and tender as the Cabbage Colewort, for which reaſon it is rarely cultivated now for table, except by the farming gardeners, who raiſe large quantities in fields for the ſupply of markets.

On account, however, of its hardineſs, it merits culture to ſtand till towards the end of winter, as a ſubſtitute, if the Cabbage Coleworts are cut off; in which caſe it may prove a neceſſary plant.

They are raiſed, for winter uſe, by ſowing the ſeed in July, as directed for Cabbage Coleworts, which ſee.

This ſort is frequently cultivated in fields for the feeding milch-cows in ſpring, for which purpoſe the cow-farmers about London uſed to raiſe vaſt quantities, ſowing the ſeed in July, and is ſometimes ſown where the plants are to remain, ſo hoeing them out to ſix or eight inches diſtance; but as the ground is ſometimes not cleared from other crops by the time the ſeed ſhould be ſown, it is then ſown thick in the corner or ſide of a field, and the plants are afterwards tranſplanted.

*Fourth Diviſion.*

[4]BRASSICA *Caulo-rapa*, Turnep-Cabbage.

This is a ſingular variety of Cabbage, having its ſtalk ſwelled globularly like a great turnep, and is crowned by a large tuft of leaves, which never cloſe or cabbage.

*There are two varieties.*] Turnep-Cabbage, with the turnep above-ground—Turnep-Cabbage, with the turnep under-ground.

The plants riſe and grow for ſome time like common cabbage-plants, after which the ſtalk of the firſt ſort begins to ſwell at bottom, and continues ſwelling upward, till by degrees the whole is ſwelled like a very large turnep, which, in the ſecond ſort, is almoſt wholly within the ground; both ſorts are crowned by a cluſter of open leaves, and they are ſometimes uſed as eſculents.

It is the globular or turnep-part of the plant that is uſed, being ſometimes ſliced in ſoups, and by ſome uſed as common turneps; but unleſs uſed when quite young, are intolerably rank and unpalatable, ſo are principally admitted in gardens as curioſities.

They are however recommended for culture in fields for feeding cattle, particularly ſheep; their chief merit is their hardineſs, as they will ſurvive the hardeſt winter.

They are propagated by ſeeds, ſown annually in March or beginning of April, and the plants are in May, or early in June, to be tranſplanted into an open ſpot, in rows two feet aſunder, keeping them clean from weeds, and draw a little earth about the bottom of the ſtem, and the turnep-part will be fully grown by Michaelmas, and continue all winter.

Or they may be ſown where the plants are to remain, and hoed out to a proper diſtance.

*Fifth Diviſion.*

[5]BRASSICA *Cauliflora*, *Cauliflora*, or the Cauliflower.

The Cauliflower, as we formerly obſerved, is ſuppoſed to be a variety, accidentally obtained from the ſeed of ſome of the ſorts of common cabbage, and brought to its preſent improved ſtate by the effect of diligent culture, which improvement was firſt of all obtained in the iſland Cyprus, from whence the ſeeds were introduced into the different countries of Europe; and our Britiſh gardens now boaſt the ſuperiority, by exhibiting the plants in greater perfection than moſt parts of the world.

There is however an apparent ſpecific difference betwixt the common *Braſſica* and the Cauliflower, both in their general growth and eatable parts; the cabbage hath broad, roundiſh, thick leaves, and when it ſhoots up ſtalks for flower and ſeed, riſes with only one main flower-ſtem immediately from the head, though it divides upward into many branches. In the *Cauliflora* the leaves are long, narrow, erect, and pointed, and when it ſhoots, riſes with many ſtems, each of which alſo divide into many branches. It is the leaves of the cabbage only that are uſed; but of the Cauliflower, the ends or buds of the flower-ſtalks; for the large, white, curdly head, in the centre of the plant, is only a compact collection of numerous buds, or ends of ſhoots, growing ſo cloſely together in a great round cluſter as to aſſume the appearance of one compact head, but which, as juſt obſerved, being compoſed entirely of the ends of numerous advancing ſhoots or flower-buds, they, after a certain period of growth, divide, and run up into ſtalks the ſame year for flower and ſeed; but while they remain compact and undivided as above, they are in perfection for eating.

*The Botanic Title and Deſcription.*

BRASSICA *Cauliflora*.

*The Cauliflora, or Cauliflower.*] Braſſica with

many branching flower-ſtems, riſing immediately from the head of the ſtalk.

*Varieties are*] Early Cauliflower—Late Cauliflower.

In reſpect to theſe two varieties, they are alike in their growth and ſize, only the early kind will come in about a week before the other, provided the true ſort can be obtained, of which however there is no depending, unleſs you ſave the ſeed yourſelf from the earlieſt ſorts, as is the practice of the London kitchen-gardeners, who are always in poſſeſſion of an early and later kind, of the former of which they are very choice.

Both the varieties are of a delicate temperature, being, for the general part, too tender to reſiſt the cold of our winter without the aid of occaſional ſhelter of glaſſes, &c.

*Their General Culture.*

The principal ſeaſon of Cauliflower is May, June, July, and Auguſt; however, by performing three or four different ſowings and tranſplantations, they may be obtained from May until near Chriſtmas.

The curious in Cauliflowers generally have three or four different crops annually, i. e. the early ſummer crop—main ſummer crop—late ſummer crop—and the autumn or Michaelmas crop.

The ſeaſons for ſowing the above different crops are,

1. The early and main ſummer crop is ſown about the twentieth of Auguſt, and the plants riſing the ſame ſeaſon, are to be pricked out and preſerved through the winter under bell or hand-glaſſes, frames, or in warm borders, &c. as hereafter directed, which being tranſplanted in ſpring, arrive at perfection the enſuing ſummer, ſome in May, but the principal crop in June and July, and ſome continue in ſucceſſion until Auguſt.

2. The late ſummer crop, to ſucceed the above, is ſown in February, or early in March, and planted out in May, as hereafter ordered, which come in for uſe in Auguſt and September, though they will be inferior to the former crop in ſize and beauty.

3. To have a Michaelmas or autumn crop, another ſowing is performed about the 24th of May, which being planted out in July, come in after Michaelmas, arriving to perfection gradually in October, November, and part of December; but the Cauliflowers of this crop are never ſo large, fair, nor perfectly headed as the ſummer crops; but as they are always acceptable, it is neceſſary to have them, and the London gardeners always raiſe great crops at that ſeaſon, which they commonly call Michaelmas Cauliflowers.

But we ſhall proceed to treat ſeparately of the culture of each of the above crops.

Firſt of the early and main ſummer crop.

As above hinted, the early and main ſummer crops are obtained from plants raiſed in autumn, and preſerved through winter under bell or hand-glaſſes, garden-frames, or in warm borders. The time for ſowing is, as before obſerved, ſome time between the 20th and 24th of Auguſt, though the London gardeners are punctual to the 21ſt day; for as they cultivate large quantities, have by long experience found that to be the moſt ſucceſsful period for ſowing this crop, which, if ſowed ſooner in autumn, many of the plants are apt to button, as they term it, in winter, or early in ſpring, that is, they run to flower in their infant ſtate, forming heads in the centre not larger than round buttons, ſo become uſeleſs; and if ſown much later, they will not acquire due ſtrength before winter, nor attain due perfection at the proper ſeaſon; mark therefore the time of ſowing, as above.

Great attention is neceſſary to procure good ſeed, ſuch that is not more than one year old, and that have been ſaved from the prime ſorts.

At the proper time, therefore, prepare a bed of the richeſt light earth in the full ground in a free expoſure, by digging it neatly one ſpade deep, and break the ſurface fine; then, directly, either ſow the ſeed on the ſurface, and rake it in even and lightly, or may firſt rake the ſurface ſmooth; then ſow the ſeed, and ſift light earth over it a quarter of an inch thick, or, after raking the ſurface ſmooth, may, with the back of the rake, ſhove the earth from off the ſurface equally, near half an inch deep into the alley, and then ſow the ſeed; then, with the teeth of the rake, draw the earth back again over the bed with a kind of jerk, to make it ſpread evenly in every part over the ſeed, and then with the rake lightly trim the ſurface ſmooth. Some adviſe ſowing this ſeed particularly upon old cucumber or melon-beds; there is no merit in this practice, ſince the ſeed will certainly grow better in a bed of good, rich, moiſt earth, in the full ground, than in the exhauſted mould of an old hot-bed.

If the weather proves dry, gentle waterings in an evening is neceſſary, which is eligible

eligible both before and after the plants appear.

The plants generally appear in a week or ten days; all the culture neceſſary is occaſional water and weeding until the latter end of September, when their leaves will be an inch or two broad; then it is proper to prick out a quantity of the beſt plants, in four feet wide beds of rich earth, in rows three or four inches diſtance, rejecting all crooked and black-ſhanked plants, and, as ſoon as planted, give a moderate watering, which, if dry weather prevails, muſt be moderately repeated; here let them remain until the end of October, or beginning of November, then muſt be tranſplanted into their winter quarters, ſome to be planted out finally under hand or bell-glaſſes for the earlieſt crop, ſee HAND-GLASSES; others into garden-frames, to be occaſionally ſhielded with glaſſes till ſpring, then planted out; or, in default of frames, ſome may be planted cloſe under a ſouth wall, where they will often ſurvive the winter tolerably well.

With reſpect to the earlieſt crop under hand or bell-glaſſes, as juſt mentioned, the following is their culture. In the end of October, or beginning of November, as above hinted, ſelect a plat of the richeſt ground in one of the beſt-defended quarters of the kitchen-ground; this ſhould be well dunged with that of old cucumber or melon-beds, and the whole then regularly trenched one good ſpade deep, burying the dung equally, then divide the ground into beds a yard wide, with foot-wide alleys between bed and bed, for the convenience of going in to raiſe, and ſet off and on the glaſſes, &c. this done, proceed to put in the plants, allowing three to each glaſs, though the London gardeners generally plant five, but if they all ſurvive the winter, two of the beſt is enough to be left to come to perfection; however, at the time of planting them under the glaſſes, ſelect for that purpoſe a quantity of the handſomeſt, ſtrait, clear-ſhanked plants; theſe being ready, ſtretch your line along the middle of the beds, and at every yard diſtance put in three plants in a triangle five or ſix inches apart, or, if you plant five, ſet one in the centre, and the others regularly round it; directly give a little water, and put on the glaſſes, which keep cloſe about ten or twelve days, when the plants will have taken freſh root; then prop them up on the ſunny ſide about three inches high with forked-ſticks, pieces of brickbat, or the like, but it is the moſt handy to have wooden pegs fifteen inches long, each having one or two notches to receive the edge of the glaſs, ſo ſticking them in the ground, one for each glaſs, and by which the glaſſes may be readily propped higher or lower on any ſide, as occaſion requires.

During winter, the glaſſes are to be kept almoſt conſtantly over the plants, obſerving, however, in mild weather, to keep them tilted on props, as above, on the warmeſt ſide, for the admiſſion of air, and in fine mild days it is proper to ſet the glaſſes quite off, which, if your plants are rather forward in growth, ſhould be practiſed at all opportunities, leſt, by too conſtantly glaſſing, it draw them into flower, but always put the glaſſes over the plants at night; when cutting winds and froſty weather prevail, keep the glaſſes cloſe down, only raiſing them in the middle of ſunny days, and when extremely ſevere froſt, keep them as cloſe as poſſible, and, for the greater ſecurity at ſuch times, it is eligible alſo to lay ſome long litter cloſe about the lower part of each glaſs, raiſing it higher as occaſion ſhall require, all of which precautions are to be occaſionally repeated from the time of planting them under the glaſſes until ſpring.

As to their ſpring culture, in the firſt place obſerve, that if all the plants under each glaſs have ſurvived the winter, they muſt be thinned the beginning or middle of March, for two ſtout plants under a glaſs is ſufficient finally to remain; though in large bell-glaſſes, the market-gardeners about London frequently leave three plants under each, for the ſake of having the advantage of the glaſſes to bring as many as poſſible to early perfection, which, though ſmaller than if but one or two, yet by coming in two or three weeks earlier than thoſe planted out, they ſell at double or treble the price; but where the ſize of the Cauliflower is a principal object, I ſhould adviſe to leave but two of the beſt plants at moſt under each glaſs, and tranſplant the others into another place the beginning or middle of March, according to the temperature of the ſeaſons, at which time a piece of rich well-dunged ground muſt be prepared to receive them; when this is ready, proceed to thin out the weakeſt plants as above, raiſing them with the point of a trowel, to preſerve the fibres of their roots, being careful not to diſturb, or leave any vacancy about the remaining plants, obſerving, if there are any deficiencies, to make them good, in the firſt place, with

ſome of the beſt of thoſe thinned out, and plant the reſt in the place prepared for them, two feet and half diſtance each way, and give ſome water to ſettle the earth about their roots; but in planting out theſe plants, it is cuſtomary with gardeners, who have occaſion to make the moſt of their ground, to ſow a crop of radiſhes and ſpinach on the ſame plat, as directed for the main ſummer crop.

The remaining plants under the glaſſes ſhould directly have the earth made good about them, and draw a little mould up about their ſtems, continuing to cover them occaſionally with the glaſſes, which muſt be raiſed conſiderably on props, in proportion to the advanced growth of the plants, not omitting to let the plants enjoy the benefit of the full air in mild days, alſo that of warm ſhowers, by ſetting the glaſſes wholly off.

Thus the glaſſes are to be continued occaſionally over the plants until the middle or latter end of April, or longer, if it ſhall ſeem neceſſary, either according to the growth of the plants, or temperament of the weather, obſerving, that when the plants are ſo far advanced that their leaves preſs againſt the glaſſes, theſe ſhould be raiſed, by forming a border or ridge of earth round each hole of plants three or four inches high, on which ridge of mould ſet the glaſſes, continuing to prop up one edge occaſionally, as before, and accordingly as the plants advance in growth, it is proper to prop up the glaſſes on every ſide three or four inches in height, for now, as the length of the days and warmth of the weather encreaſes, the plants will grow freely, ſo muſt have as much free air and ſcope to grow as it is poſſible to allow them under the glaſſes, at the ſame time being careful to expoſe them alſo occaſionally to the full air, as before obſerved, in fine days, and moderate warm ſhowers, but continue to defend them with the glaſſes on nights, and in immoderate cold rains, and all boiſterous weather, at leaſt until the weather becomes warm, and the plants are grown too large for the glaſſes, then let them by degrees be fully expoſed night and day, ſo that by the middle or latter end of April, the uſe of glaſſes may be wholly diſcontinued.

If the weather, toward the middle or latter end of April, and beginning of May, prove hot and dry, moderate waterings will be of utility in promoting the progreſs of the plants, as well as encreaſing their ſize and ſtrength; for it is of importance to have the plants as large and ſtrong as poſſible when arrived at full growth, otherwiſe we cannot expect them to produce large Cauliflowers.

About the middle of May ſome of the forwardeſt plants will probably ſhew flower, at which period examine your plants daily, and whenever a flower appears, turn down ſome of the inward leaves, to ſcreen it from the Sun's rays and free air, which would change it to a yellow hue, and occaſion the head to open before it attained its due perfection.

The excellence of a Cauliflower conſiſts not only in the ſize, but alſo in the whiteneſs and compact curdy-like growth of the head; ſuch that aſſume a frothy looſe appearance, are a degeneracy, and are in every reſpect inferior.

A Cauliflower is in its utmoſt perfection of growth when the outward parts of the circumference begin to open and expand, after which appearance the whole head ſoon divides, and ſhoots up faſt for flower and ſeed, therefore watch the opportunity, for a day or two often makes conſiderable difference.

In gathering the Cauliflowers for uſe, it is worth obſerving, that they eat conſiderably more criſp and ſweet when cut in a morning, though this is not always practicable in families, becauſe it is often the middle of the day before the gardener is informed what is wanted for the kitchen: they may either be cut off the ſtalk as it ſtands, or the whole plant may be pulled up; for, as the ſtalks never produce ſprouts like thoſe of cabbages, it is of no uſe after the main head is gone; they however muſt be diveſted of the root-end of the ſtalk before they are carried in to the kitchen or market; but if they are not to be immediately uſed, permit the whole ſtalk and leaves to remain, and lay them in a cool place till wanted.

Thus far for the culture of the bell-glaſs crop.

As to the culture of the main ſummer crop, which I before adviſed to be wintered in frames, &c. obſerve the following directions.

Theſe are deſigned to be protected all winter in frames, &c. in order to be planted out in the ſpring, to ſucceed the early crop which were finally planted out in autumn under the bell or hand-glaſſes; and even where there are no ſuch glaſſes, it is eſſentially neceſſary to raiſe a quantity of plants in autumn, as before directed, and pricked in garden-frames, to be occaſionally covered with the lights during

ing

ing winter, becauſe they will come in much ſooner than a ſpring-ſown crop; or, in default of frames, prick a quantity in a bed arched over with hoops to be covered with mats, for, although ſome may be planted cloſe under the bottom of a warm wall to take their chance, and will frequently ſtruggle through our ordinary winters, yet they are not always to be depended on, and, at any rate, they come in later, and rarely attain the ſize and perfection of thoſe occaſionally protected as above.

Therefore the plants being raiſed as before directed, proceed, in the end of October, or beginning of November, to prepare a bed or beds of rich light earth, in a dry ſunny ſituation, the width and length of one or more garden-frames, &c. fronting the ſouth, raiſing the ſurface a few inches above the common level, and rake the top ſmooth; then mark out the width of the frame, and prick the plants therein in croſs rows three inches aſunder, give a little water, and directly put on the lights, which keep conſtantly on eight or ten days, when the plants will have taken root, and muſt then be fully expoſed, in mild weather, to the open air. During winter, every day, in open weather, expoſe the plants fully to the free air, by ſhoving the glaſſes entirely off, which, however, ſhould always be put on a-nights; likewiſe in exceſſive rain, though if the rain happens in the day-time, and the weather is mild, raiſe the glaſſes on props three inches high, for the admiſſion of freſh air, for they muſt by no means be kept too cloſe in mild weather, leſt it force them into flower, as obſerved of the bell-glaſs crop, which would render them uſeleſs. In ſharp froſty weather the glaſſes muſt be kept always on, except in the middle of ſunny days, and the glaſſes ſhould be covered on nights with dry litter or mats; alſo if the froſt is very ſevere, lay long litter round the outſide of the frame. All decayed or yellow leaves ſhould be conſtantly picked off as they appear during their reſidence here. Towards ſpring innure them gradually to the full air, by leaving the glaſſes off occaſionally on nights as well as days, in open mild weather, ſo as that by the end of February, or beginning or middle of March, they may be hardened to be removed to the place of their final deſtination.

In default of frames, &c. as above obſerved, you may, at the before-mentioned time, prick a quantity of plants in a four feet wide bed in a ſheltered ſituation, which arch over with hoops or rods; ſo on nights and all bad weather cover with large garden-mats, and in ſevere weather alſo with litter.

Likewiſe in the above caſes of the want of frames, &c. a quantity may be pricked on a ſouth border cloſe under the wall, &c. and in default of other covering, they may be lightly covered in ſevere froſt with dry long litter, by which aſſiſtance the plants will often ſurvive the winter, and, at any rate, will come in earlier than ſpring-ſown plants.

In the latter end of February, or beginning or middle of March, according to the temperature of the weather, and condition of your plants, all thoſe wintered as above, either in the frames, arched bed, or warm border, are to be planted out, where they are finally to remain. Make choice of an open ſpot of the beſt ground, which ſhould be previouſly dunged and dug, as directed for the early crop, and in which plant the Cauliflowers by line two feet and half diſtance every way, and give water; but if it is neceſſary to make the moſt of your ground, a crop of radiſhes and ſpinach may alſo be raiſed on the ſame plat, which ſhould be mixed and ſown together broad-caſt, and raked in, before you plant the Cauliflowers. The radiſhes and ſpinach come in for uſe in May, and will be all gone by that time the Cauliflower-plants begin to advance conſiderably, when the ground ſhould be well hoed, and earth drawn about the ſtems of the Cauliflowers, obſerving, if the month of June proves very hot and dry, occaſional waterings will be of great utility, forming baſons round each plant for that purpoſe, and in July this crop will be in full perfection, continuing in ſucceſſion until the middle of Auguſt, when they will be ſucceeded by the late ſummer crop.

The culture of the late ſummer crop is,

In order to keep up a regular ſucceſſion of Cauliflowers through the ſummer, it is neceſſary to raiſe a due ſupply of plants in ſpring, to be planted out in the latter end of April, or in May, which will arrive at perfection in Auguſt and September, in due time to ſucceed the autumn-raiſed crop.

This crop may be ſown any time in February, but not later than the firſt week in March, and, in order to forward the plants as much as poſſible, it is proper to ſow the ſeed in a hot-bed of ſlender ſtructure; let the hot-bed be made for a one-light box about eighteen or twenty inches depth of hot dung, covered with light rich earth four or five

five inches thick; ſow the ſeed on the ſurface, and cover it a quarter of an inch deep with fine mould, put on the glaſs, and give occaſional light ſprinklings of water, raiſing the glaſs daily, for the evaporation of the ſteam, and admiſſion of freſh air, and the plants will riſe in a few days, at which time admit air freely by tilting the glaſs, and by taking it wholly off in fine warm days and moderate ſhowers, and in dry weather give frequent light waterings. When the plants have leaves an inch broad, it is proper to prick them out, and if ſome are then pricked upon another hot-bed of moderate temperature, it will forward them conſiderably. In default of frames, may ſow the ſeed and prick the plants on a hot-bed of the above ſubſtance, defended in cold nights and bad weather with mats or hand glaſſes; or, for want of a hot-bed, may ſow the ſeed, &c. on a warm border, and cover occaſionally, as above.

About the latter end of April, or beginning of May, ſome of the forwardeſt plants will be fit to tranſplant for good, which ſhould be in an open ſpot of rich well-dunged ground, as directed for the former crops, and in dry weather ſhould have frequent refreſhments of water till they have taken good root; their further neceſſary culture is only occaſional hoeing to kill weeds, and when the plants are ſomewhat advanced in growth, draw ſome earth about their ſtems.

The culture of the Michaelmas crop is,

To have Cauliflowers after Michaelmas, and to continue from October till near Chriſtmas, is, as already obſerved, effected by ſowing about the 24th of May on a bed of common earth, and when the plants have leaves an inch or two broad, prick them out three or four inches aſunder, to remain until the latter end of July, then tranſplant them finally, as directed for the other crops, ſupplying them occaſionally with water till rooted; they will begin to ſhew heads towards the end of October, which will continue coming in gradually all November, and if the ſeaſon proves mild, they often continue great part of December.

This crop depends greatly on the temperature of the autumn after Michaelmas, which, if moderately dry and warm, we often have tolerably large handſome Cauliflowers in November, but if very wet and cold, the heads, for the general part, are ſmall, irregular, ill-coloured, and inſignificant.

*Saving the Seed of theſe Plants.*

Every gardener who cultivates any conſiderable quantity of Cauliflowers, ſhould be particularly anxious about ſaving his own ſeed from the moſt perfect ſorts, as thoſe who ſave great quantities for ſale are not over careful in that point, which is the reaſon we often meet with ſo many irregular, ill-coloured, frothy, looſe, and other ſpurious kinds, in private gardens, to the great diſappointment of many gardeners.

Some of the earlieſt ſorts of the bell or hand-glaſs crop, are to be ſelected for ſeed, for thoſe of the ſucceeding crops are rarely forward enough to ripen any; the moſt perfect, largeſt, compact, firm white heads, are to be marked, and permitted to remain in the ſame place to run up to ſtalks, &c. which they will effect in July, when they will alſo flower, or in the beginning of Auguſt, and perfect ſeeds in September; obſerving, when the flower-ſtems are conſiderably advanced, to place three ſtakes triangle ways, for the ſupport of each plant, and by encompaſſing the ſtakes with pack thread, or other tying, it will effectually ſecure the ſtems, and all the lateral branches, in their due poſition, which is all the culture neceſſary, unleſs the weather proves very dry after the ſeed pods are formed, when ſome moderate waterings all over the plants will be very ſerviceable, not only in the growth of the ſeed, but alſo in preſerving it from the mildew, an infection which often attack theſe plants ſo ſeverely in their ſeeding ſtate, as either totally to deſtroy the greateſt part of the ſeed, or retard its growth ſo much, that it never ripens perfectly, and is the reaſon of good Cauliflower-ſeed being often ſo dear, which in the ſhops is frequently ſold from two to four ſhillings per ounce.

In the middle of September the ſeed will begin to ripen, though in cold wet autumns it is ſometimes Michaelmas before that is thoroughly effected, being watchful, however, to cut off the branches according as the ſeed ripens, for they do not all ripen together, ſo tye it in bunches, and hang it in the ſun to harden, then beat it out, and put it up in bags for uſe.

A freſh parcel of ſeed ſhould be ſaved annually, for this ſeed is not to be depended on when more than one year old, though two year old ſeed will frequently grow.

*Sixth Diviſion.*

[6]BRASSICA *Italica*, Italian *Braſſica*, commonly called Broccoli.

The Broccoli is another ſuppoſed variety of the common cabbage, though, if we admit of the cauliflower as a diſtinct ſpecies of *Braſſica*, the Broccoli is more apparently related

lated to that ſpecies than the cabbage, ſo that we have reaſon to ſuppoſe all the ſorts of Broccoli varieties of the *Braſſica Cauliflora*, as the plants, both in their general growth, habit, and eatable parts, greatly reſemble that ſpecies; for, as we obſerved of the *Cauliflora*, all the varieties of Broccoli form roundiſh heads in the centre of their leaves, compoſed entirely of a compact collection of numerous buds or ends of advancing ſhoots, and which, like the cauliflower, are the chief eatable parts of the plant; that being uſed while they remain compact and firm, are moſt excellent eating, but after having attained a certain ſtate of growth they divide, aſſume a ſeedy-like appearance, and ſoon fly up to ſtalks for flower and ſeed.

There are ſeveral varieties, all of which are cultivated principally for winter and ſpring eating, though the ſpring crops always attain the greateſt perfection, being productive of the largeſt and fineſt heads; but, as a regular ſucceſſion may be obtained from Michaelmas until May-day, and being the moſt excellent winter and ſpring vegetables of our gardens, their culture highly merits our niceſt attention, to obtain a regular ſupply during the above period.

All the varieties are hardy enough to reſiſt the cold of our ordinary winters, though very ſevere froſt often affects ſuch that are weak or grow in expoſed cold ſoils, but more particularly the ſort called Cauliflower-Broccoli.

The botanic title of Broccoli is,

BRASSICA *Italica*, the Italian *Braſſica*, by the Italians called Broccoli.

The principal ſorts, and their reſpective varieties, are,

[1]*Early Purple Broccoli.*] A moderate-growing darkiſh-green plant, producing ſmalliſh purple heads, but comes earlier by a fortnight or more than any other, and of which there are, the purple, the green, and the blue, all often riſing from the ſeed of the ſame plant; this ſort is proper for the firſt crop, which, if ſown the latter end of March, or beginning of April, and planted out in June, come in for uſe from Michaelmas till Chriſtmas, and when the heads are gathered, the ſtalks produce plenty of fine ſprouts of excellent eating.

[2]*Late Purple Broccoli.*] A large, robuſt-growing, darkiſh-green plant, producing a large purpliſh head like a cluſter of buds, being generally much larger and more perfectly headed than the former ſorts, and is very delicate eating, of which there are, the Common Purple-headed Broccoli—Blue Broccoli—Brown Broccoli—Green Broccoli—Yellowiſh Broccoli—all of which frequently riſe from the ſame ſeed, though that of the true purple kind is ſuperior both in ſize and perfectneſs of heading, as well as delicacy of eating, and with care in ſaving the ſeed, the ſorts may be continued, and this, and all its varieties, by ſowing in April, or early in May, and beginning of June, and planting out the plants in July and Auguſt, may be obtained for uſe from about Chriſtmas until the beginning or middle of May, but are always in greateſt perfection in regard to ſize in March and April; and after the main head is cut, the ſtalks exhibit abundance of ſide ſhoots or ſprouts, terminated by ſmall heads, which eat as ſweet and tender as the main ones.

[3]*White, or Cauliflower-Broccoli.*] A very curious variety of Broccoli. The plants are of robuſt growth, and lightiſh-green colour, forming fine white heads in the centre, ſometimes as large as a middling cauliflower, and greatly reſemble them in every ſtate of growth, and for delicacy of eating is equal to the fineſt ſummer cauliflower whatever. This ſort admits of no varieties, except in different degrees of whiteneſs, though the whiteſt generally aſſumes ſomewhat of a yellowiſh hue; that, by ſowing ſeed in April and May, and planting out the plants in June, July, and Auguſt, you will obtain heads for uſe all winter and ſpring; but thoſe that appear about March, and beginning and middle of April, are conſiderably the largeſt and faireſt heads. The ſtalks of this ſort rarely afford any ſprouts like the purple kinds.

[4]*Black Broccoli.*] A tall-growing plant of a blackiſh-green colour, which, for the general part produce ſmall and imperfect heads, being ſomewhat open and ſeedy-like, but poſſeſs this property of being ſo hardy, as ſeldom to be injured by the ſevereſt froſt. There are of this the Black or Dark-headed Broccoli, the Brown, and the Blue, all ſometimes from the ſame ſeed, and are proper to cultivate to ſtand the winter, by way of reſerve for ſpring ſervice, ſowing the ſeed early in May, and planting out the plants in July.

*Their General Culture.*

All the varieties are propagated by ſeed annually in the common ground, ſowing them in ſpring in an open ſituation, and the plants

to

to be tranſplanted into an open expoſure, as hereafter directed, to grow to perfection.

The principal ſeaſons for ſowing is March, April, and beginning of May, according to the time the plants are required for uſe; as for inſtance, if the heads are deſired in October, November, December, and January, it is proper to ſow ſome of the early and late purple kinds any time from about the 20th of March to the fifth of April; alſo at the ſame time may be ſown a few of the Cauliflower-Broccoli, by which you will obtain the greater chance of ſucceſſion and variety; the early purple will come in firſt, and they will be regularly ſucceeded by the others; but for the main ſpring crops, to come in for uſe in January and February, and continue in ſucceſſion until May, the ſeaſon for ſowing them is from about the fifteenth of April until the fifth of May, according to your ſituation and temperature of ſoil, and for which crops the late purple and Cauliflower-Broccoli are the principal ſorts; at the ſame time may alſo ſow ſome of the Black-Broccoli, to ſtand by way of reſerve, in caſe the others are injured by the winter's froſt; and if you would continue a longer ſucceſſion, a third ſowing may be performed the end of May, or beginning of June, particularly of the late purple and Cauliflower-Broccoli.

By obſerving the above different times of ſowing the ſeed, a ſucceſſion of Broccoli may be obtained for uſe from October until the middle of May.

The ſeed, as before obſerved, ſhould be ſown in an open expoſure, where the plants will riſe much ſtronger than on narrow borders, under walls, &c. ſow each ſort ſeparate, ſcattering the ſeeds moderately thick on the ſurface, and rake them in; the plants will come up in ten or twelve days; give occaſional waterings in dry weather, and when they have leaves an inch broad, it is proper to prick out a quantity of the beſt in a nurſery-bed three or four inches apart, giving water as ſoon as planted, and occaſionally till they have taken root, in which bed let them remain a month, or five or ſix weeks, where they will acquire due ſtrength, their ſhanks will be ſhort and of robuſt growth, and will hereby be conſiderably better prepared for tranſplanting where they are finally to ſtand, than thoſe which remain in the ſeed-bed.

The time for tranſplanting them where they are finally to remain, is June, July, Auguſt, and beginning of September, according to the time they were ſown, or are deſired for uſe.

The plants ſhould have an open ſituation, and as good ground as any the garden affords, which, if it has the addition of dung, will be a particular advantage, digging it in neatly one good ſpade deep, and directly put in the plants, for which work a moiſt time would be highly beneficial; they are to be planted in rows two feet and half aſunder, and about twenty inches diſtant in the lines; but for thoſe planted late, i. e. in Auguſt and September, two feet at moſt between row and row is ſufficient, and eighteen inches diſtant in the rows. Let them, as ſoon as planted, be watered, and if dry weather prevail, repeat the watering every other day, till the plants have got root, which work ſhould be particularly attended to in tranſplanting theſe plants.

After the plants have taken root and begin to grow, their further culture is to keep them clear from weeds, by hoeing the ground occaſionally, and when they have advanced a little in growth, draw ſome earth with an hoe about their ſtems, which work of earthing, if repeated, will be of ſingular advantage to the plants; it will promote their rooting more firmly in the ground, and encourage their progreſs of growth, and greatly forward them, ſo as to acquire due ſize and ſtrength before winter, which is very eſſential, for if the plants do not by that time arrive to a tolerably large growth, they will yield but ſmall and trifling heads.

Some of the earlieſt plants will probably ſhew heads for uſe in October and November, or perhaps ſooner, which however are rarely ſo large and fine as thoſe that appear towards, and after Chriſtmas.

Previous to gathering the Broccoli for uſe, attention muſt be had that the heads be permitted to have their full growth, which, however, ſhould be cut while they remain cloſe, and before they begin to divide and aſſume a ſeedy like appearance, and ſhould be cut with about ſix inches of the main ſtalk to each head; for the upper part of the ſtalk eats exceeding ſweet and tender, which, previous to its being dreſſed, muſt be peeled or diveſted of the outer rind, and which, when dreſſed, as well as the heads themſelves of the Purple and Black-Broccoli, always aſſume a fine green colour; but the Cauliflower-Broccoli retains its natural whiteneſs, which ſhould be boiled in a clean linen cloth, as practiſed to

cau i-

cauliflower, and ſhould be ſerved up to table in the ſame manner.

After gathering the main heads of all the ſorts of Purple and Black Broccoli, the ſtalks ſhould be permitted to remain for the production of ſprouts or ſmaller heads, which they will afford plentifully, and which are as fine eating as the principal heads; but as to the Cauliflower-Broccoli, the ſtalks afford but very few ſprouts or ſide-ſhoots.

To ſee Broccoli in high perfection from the earlieſt to the lateſt period, we muſt review Covent-garden and Newgate-markets, in London, early in a morning from October until May, there we may ſee the production of numerous different gardeners brought in great quantities, all bound up in bunches by their ſtalks, from ſix to twelve heads in each bunch, thoſe of the purple ſorts all diveſted of their leaves, the cauliflower kinds with the leaves on, but which are trimmed down to the head in the manner of cauliflowers, and both of which ſorts are there ſold from about three or four to eight or ten ſhillings per dozen of bunches, according to the ſize and quality of the heads.

*Of ſaving the Seed of the different Sorts.*

When it is intended to ſave the ſeed of Broccoli, ſome of the largeſt and moſt perfect heads of the reſpective ſorts of thoſe which appear in February or March ſhould be marked when in perfection, which, of the firſt and ſecond ſorts, thoſe only of the beſt purple colour and cloſe knobby-like heads ſhould be ſelected; and of the cauliflower or white ſort, thoſe that have the largeſt, cloſeſt, and whiteſt heads, are to be choſen; and of the black kind, always chuſe thoſe with the largeſt, moſt compact, and darkeſt-coloured heads; all of which ſhould remain untouched, only taking off the ſide-ſhoots, ſo leaving only the principal head to ſhoot up for ſeed.

To preſerve the principal varieties as pure in their kind as poſſible, the ſeeding plants of the different ſorts ſhould be at a conſiderable diſtance, leſt they fecundate each other, and occaſion a degeneracy.

Thoſe perſons who cultivate purpoſely for ſeed, ſhould ſow in the end of April or beginning of May, and plant them out in July; and the following ſpring, when they ſhew their heads, pull up all thoſe that are degenerated, or vary from their reſpective kinds, which ſhould be punctually attend to, otherwiſe it will be impoſſible to preſerve the ſorts.

All the ſorts generally ripen ſeeds as plentifully as any of the ſorts of cabbages.

The plants generally run up to ſtalk in April or May, flower in June, and the ſeed ripens in Auguſt, which is to be managed as directed for that of cabbages, ſavoys, &c.

*Seventh and laſt Diviſion of Braſſica.*

[1]BRASSICA RAPA, the Turnep.

The Turnep, as we have already obſerved, is a diſtinct ſpecies of *Braſſica*, or Cabbage, which till lately was always ranged as a ſeparate genera, under the title of *Rapa*; but its general characters being the ſame as *Braſſica*, modern botaniſts have now ranged it as a ſpecies of that genus.

Claſs, order, and characters, the ſame as *Braſſica*.

The botaniſts allow but one diſtinct ſpecies, but which admit of ſeveral eminent varieties, all of which are annuals, as, if ſown early in ſpring, they attain perfection, run up to flower, ripen ſeeds, and totally periſh the ſame year.

The ſpecies is,

BRASSICA *Rapa*.

*Rapa, the Turnep* ] Braſſica with a large, orbicular, depreſſed, fleſhy root, crowned by many long rough leaves, and when the plant ſpindles, riſes with a ſtrong erect ſtem three or four feet high, dividing into many branches, covered with numerous yellow flowers in May and June, ſucceeded by plenty of ripe ſeed in July or Auguſt.

Varieties of this are,

[1]*Early Dutch Turnep.*] An orbicular, moderate ſized, handſome, white Turnep, valuable for its early perfection, very ſweet and tender while young, and a very fine garden Turnep for the early and ſummer crops, though when old it is apt to become ſtringy.

[2]*White Round Turnep.*] A globular, large, white Turnep, proper both for the garden and field culture, and ſucceeds the Dutch ſort in its time of attaining perfection.

[3]*Green-topped Turnep.*] A large round Turnep, remarkable for having its outer coat green at top, and great part of the root growing above-ground; is exceeding tender and palatable eating at almoſt every period of its growth, obtaining in ſize from about four to eight or ten inches diameter, though, when allowed conſiderable room to grow, it often arrives at a much greater magnitude, and is excellent for the general crop in gardens, as well as that of field-culture for feeding cattle.

[4]*Red-topped Turnep.*] A large globular Turnep, having its outer ſkin red at top; a fine,

ſoft, ſweet-eating root; and as it acquires a very large ſize, is alſo particularly well adapted for field-culture.

[5]*Yellow Dutch Turnep.*] A moderately large, and frequently oblong Turnep, the ſkin and fleſh of a yellow colour; is tolerably ſweet and palatable eating, though the colour renders them diſagreeable to ſome, whilſt others eſteem them equal to any of the other varieties for the table.

[6]*Oblong White Turnep.*] An oblong, largiſh, white Turnep; ſtrikes conſiderably into the ground, often aſſuming the form of ſome parſneps; boils ſoft and ſweet while young, but ſoon becomes ſtringy and rank-taſted.

[7]*Long-rooted French Turnep.*] A long, ſmall, ſpindle-rooted Turnep, of but little merit except for ſoups, and ſhould be uſed while young, otherwiſe it becomes ſtringy and hard.

[8]*Purple Turnep.*] A roundiſh, ſmall, early, purple-coloured Turnep, conſidered more as a curioſity, than for any œconomical purpoſes.

Of the above varieties, the firſt four are thoſe of moſt merit, the firſt of which demands notice for the early ſummer crops for family ſervice, they generally arriving to perfection a fortnight, at leaſt, ſooner than any of the other varieties, and may be obtained ſo early as the middle of May, at which time, or when the root attains the breadth of a ſhilling or a half-crown piece, they are alſo eſteemed by many to eat raw, either alone, or as an ingredient in the compoſition of a ſallad, ſerving them to table with part of their green tops entire, as alſo the long fibre or tail of the root; and for culinary purpoſes they may be continued in great perfection all ſummer, by performing three or four different ſowings from March until July, ſo as to have crops of young roots ſucceed one another regularly; but for the autumn and winter crops, the white round Turnep, the green-topped, and the red-topped kinds, are the hardieſt and very fine family Turneps, though the green-topped ſort claims precedence for ſweetneſs of eating, as well as durability of perfection; likewiſe, as the three laſt-named varieties attain conſiderably the greateſt magnitude, they are to be preferred to all the others for field-culture, for the feed of ſheep and black cattle in winter and ſpring; and for the general ſupply of table in autumn and winter, it is eligible to cultivate a good crop of the white-round, or green-topped kinds, &c. by ſowing at the ſeaſons hereafter directed.

Turneps may be obtained for uſe eight or ten months in the year, that is, from about the middle of May, until the beginning or middle of March, after which time they begin to ſhoot up into ſtalk for ſeed; and although the roots are often continued for uſe until the latter end of April, yet they, after the month of March commences, ſoon ſhoot, become ſtringy, dry, hard, and very indifferent eating for the table.

*General Culture.*

The propagation of all the varieties is by ſeed in an open ſituation, in the place where the plants are to remain, for they are never tranſplanted like the preceding ſpecies of *Braſſica*.

The ſeaſon for ſowing is any time from the beginning of March until the latter end of July, though to have a long and regular ſucceſſion for the table from the earlieſt to the lateſt period, it is neceſſary to perform four or five different ſowings, at leaſt, at proper intervals, from the middle of February until the middle of Auguſt, obſerving it is not adviſeable to ſow earlier than the middle of February, becauſe the too early ſown plants would fly up to ſeed the ſame year before the roots apple, or, at leaſt, attain a quarter their uſual ſize; indeed, even thoſe ſown any time in February are very apt to run; but thoſe ſown in March more generally ſtand, and all thoſe ſown after that time, as in April, May, June, &c. never run till the ſpring following: and as to the latter crops, none ſhould be ſown much later than the middle of Auguſt, as above noticed, by reaſon the roots will not have time to grow to any tolerable bigneſs before the winter's cold puts a period to their growth; it is however proper to ſow late as well as early for family uſe, that, although the roots will not acquire any conſiderable ſize, they being reſerved for ſpring, ſtand three or four weeks longer before they run, than thoſe of the ſummer crops, by which means we obtain them ſo much the longer for the table.

But for the general ſummer, autumn, and winter crops, the principal periods for ſowing is April, June, and beginning of Auguſt, as before obſerved, though, where a conſtant ſupply of young roots are required, ſowings may be performed in any of the intervals between theſe times, or thoſe before-mentioned.

An open ſituation, and a moderately light ſoil is the moſt eligible for the culture of Turneps; as, in confined places, they draw up greatly to tops, and form but inconſiderable roots, and in ſtrong land the roots frequently acquire a ſtringy texture, and rankneſs of taſte.

The neceſſary ſpace of ground to ſow at a time for the ſupply of a family, is from about two to ſix, eight, or ten rod, making the calculation according to the extent of the family.

The proper quantity of ſeed is at the rate of about two pounds to an acre, ſo the calculation is eaſily made for a ſmaller or larger extent of ground.

The ground is to be prepared for the ſeed, by digging or trenching it one ſpade deep, and the ſeed ſhould, if poſſible, be ſowed while the ground is freſh ſtirred, eſpecially in ſummer, when it is hot or dry weather, but a moiſt ſeaſon for ſowing is of great importance in the culture of Turneps, for reaſons hereafter explained: the ſeed is to be ſown broad-caſt on the ſurface, ſcattering it moderately thin with a regular caſt, and even-ſpreading hand, and directly tread it in evenly, and rake the ground; thus far is the method of ſowing Turneps in gardens; but in the field culture the plough, harrow, and roller, is uſed. See the *Field Culture*.

This ſeed being of quick germination, the plants appear in a few days after ſowing, eſpecially in moiſt weather; and in eight or ten weeks after they appear, we may expect Turneps fit to draw.

As we above obſerved, a moiſt ſeaſon is of great advantage in ſowing Turneps; it promotes a quick germination in the ſeeds, and free growth in the young plants; for when they come up freely, and continue a luxuriant growth, it ſecures them from the fly, which, in very dry weather, when the plants riſe ſtraggling, and grow ſtuntedly, while in the ſeed leaf, often proves a mortal enemy to theſe crops, frequently deſtroying whole fields of them in a few days; but when the weather is ſhowery at their firſt appearance, the plants advance ſo faſt in growth as ſoon to be in the rough leaf, and after they begin to advance in the rough leaves pretty ſtrongly, they may be conſidered to be paſt danger; ſo that the greateſt danger is the firſt week or fortnight after the plants come above ground, therefore in gardens, where there are only ſmall quantities, it will be highly beneficial to water them plentifully at that period of their growth. Many receipts have been recommended to prevent the attacks and devaſtations of this common enemy to our Turneps, ſuch as ſteeping the ſeed, previous to ſowing it, ten or twelve hours in water, wherein has been boiled or infuſed a good quantity of tobacco-ſtalks and duſt, mixing therewith flour of brimſtone, ſoot, juice of hepatic aloes, &c. alſo by ſtrewing ſoot or lime over the ground after the plants come up, which expedients frequently have ſome effect, though far from being infallible, for, in ſpite of all the methods, the fly will often devour whole crops, if ever ſo conſiderable; and when this is the caſe, nothing more can be done than to prepare the ground, and ſow it again as ſoon as poſſible.

As to the general culture of Turneps, the plants, as before obſerved, are always to remain where ſown, and all they require is, when about a month old, to be thinned to from about ſix to twelve or fifteen inches diſtance, and cleared from weeds, which work of thinning, &c. is the moſt effectually done by the hoe, and is called hoeing Turneps.

This work of hoeing Turneps is to be performed when the plants have two or three leaves about an inch broad, which ſhould always be done in dry weather, ſee HOEING, having a common large hoe five or ſix inches broad, with which cut down the ſuperabundant plants, ſingling out the others to about eight inches diſtance, though, if the turneps are to ſtand to grow to full ſize before any are drawn, they ſhould be thinned to a foot diſtance at leaſt; at the ſame time cut down all weeds, and ſtir every part of the ground, for this is highly beneficial to the growth of the plants, and if the work is duly performed in dry weather, that the weeds, &c. cut down be more effectually deſtroyed, the plants will require no further culture; for they, after the operation of hoeing, will advance ſo faſt in growth, that their leaves will ſoon ſpread and cover the ground, ſo as to ſtop the future progreſs of weeds. With reſpect to the above diſtances of thinning the Turneps, it is principally to be underſtood of ſuch that you intend ſhall grow to a tolerably large ſize before any is drawn; but as to the earlieſt crop, they need not be thinned to more than five or ſix inches diſtance, eſpecially if it is intended to begin drawing them as ſoon as they begin to turnep, as by many practiſed, gradually thinning out the largeſt

for uſe; obſerving, however, always to thin them regularly at firſt, as above, at the time of hoeing.

In three or four weeks after hoeing, the plants will begin to turnep, and in five or ſix ſome will be fit to draw young for uſe, but it will be two months from hoeing before they attain tolerable perfection, though, as above obſerved, we often begin drawing the earlieſt crop as ſoon as the root begins to turnep, which, although not larger than middling walnuts, are always highly acceptable at an early ſeaſon, as a rarity at table; they alſo ſell well at market, and thoſe of London are generally ſupplied with them ſo early as the beginning of May.

The quantities of theſe roots conſumed for family uſe almoſt the year round in London and its vicinity are amazing, when we ſurvey the vaſt crops in the extenſive garden-grounds and fields eight or ten miles round the metropolis; alſo Covent-garden, and the other gardener's markets of that city, early in a morning, to ſee the prodigious quantities that are daily brought by cart and waggon-loads, all clean waſhed and neatly bunched, from about twelve to fifteen or eighteen, &c. according to their ſize in each bunch, and which the gardeners ſell to the retailers by the dozen of bunches, generally from one to two ſhillings per dozen.

*Of the Field Culture.*

In the field culture of Turneps for autumn and winter ſervice, either for the ſupply of markets or for feeding cattle, the common ſeaſon for ſowing is any time from the beginning of June till the middle of Auguſt.

The ground is to be prepared for the ſeed by proper ploughing, and ſhould alſo be once or twice well harrowed, to render the ſurface level and fine, that the ſeeds, when ſown, may be more equally covered; the ſeed is then to be ſowed immediately, allowing not more than a pound and half or two pound to an acre, ſowing it by broad-caſt, and directly harrow it in with a ſhort-tyned harrow, and afterwards roll the ground with a large wooden horſe-roller to ſmooth the ſurface, and the ſeed will thereby be covered more effectually, the plants will riſe more regular, and will be much eaſier to hoe them, than if the ſurface is left rough.

When the plants have leaves an inch or two broad, they are to be hoed in dry weather, to deſtroy weeds, and thin the plants to twelve inches diſtance, as before obſerved; but when it is deſigned the roots ſhall grow to their utmoſt ſize for feeding cattle, it is proper to ſet them out to about fifteen inches diſtance at leaſt.

The crops of the above times of ſowing come in for uſe in September, October, and November, and continue good all winter, either for the table, or for feeding, at which time they are admirable food for ſheep and cattle, and are excellent for milch-cows, for which purpoſe the cow-farmers about London uſe vaſt quantities, many of whom have ſeveral hundred cows, but as their land conſiſts chiefly of graſs, they buy whole fields of them of the ploughing farmers ten or fifteen miles round the city, and bring them home in waggons, and give them to the cows whole, which they eat greedily, to the great encreaſe of the quantity of their milk.

*Saving the Seed.*

To ſave Turnep-ſeed, a due quantity of the roots of the autumn or winter crops may be permitted to ſtand where they were raiſed, and they will ſhoot up in March, and produce plenty of ſeed in June, July, or Auguſt, without further trouble; but if you are curious to preſerve the different varieties in as great perfection as poſſible, it is adviſeable in February to tranſplant a quantity of the fineſt roots of each ſort in ſeparate pieces, at a diſtance from each other, placing them in rows two feet aſunder, and the neceſſary culture is, to hoe the ground occaſionally to deſtroy weeds, and to watch the birds when the ſeed begins to ripen, which will be in June or July, and ſome time in theſe months, or beginning of Auguſt, will be fully ripened, when the ſtalks ſhould be cut up from the bottom, and after it has been expoſed to the ſun a few days to dry and harden, threſh it out, and put it up in bags for uſe.

BROMELIA, *Bromelia*, comprehending alſo the ANANAS, or Pine-Apple, and the PINGUIN, or Wild Ananas.

This genus comprehends moſt curious exotics for the hot-houſe, herbaceous perennials of robuſt aloeaceous-like growth, riſing with numerous, long, erect, ſharp-pointed leaves from the bottom; in the midſt an erect ſtalk from one to three feet high, crowned by oblong ovaliſh fruit; and that, being natives of the hot parts of Africa and America, they conſequently, in this country, require the conſtant ſhelter and temperature of our beſt ſtoves.

Claſs

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, a ſmall, trigonous, three-parted, permanent cup. COROLLA, three narrow erect petals, having at the baſe a three-parted nectarium. STAMINA, ſix ſhort filaments, inſerted into the receptacle, crowned by ſagittated antheræ. PISTILLUM, a germen below the receptacle, and filiforme ſtyle, ſurmounted by an obtuſe bifid ſtigma. PERICARPIUM, a large, roundiſh, umbilicated, baccaceous fruit, furniſhed with numerous, ſmall, oblong, obtuſe, ſmooth ſeeds, which in the Ananas are lodged in the knobs or tubercles of the fruit.

There are of this genus four or five ſpecies, the principal of which is that celebrated plant the Bromelia Ananas, which produces the ſo much admired fruit the Pine-Apple, and which now conſtitute the principal furniture of moſt of our hot houſes, for the ſake of the ſaid fruit, which certainly deſerves the appellation it has univerſally obtained, that of king of fruits, as, in beauty, delightful fragrance, and deliciouſneſs of taſte, it greatly ſurpaſſes all other fruits of the world.

The ſpecies are as follow: and firſt of the Pine-Apple and varieties.

[1]BROMELIA *Ananas.*

*The Ananas, or Pine-Apple Plant.*] Bromelia with a thick, fibry, perennial root, crowned by many long, erect, ſharp-pointed, ſerrated, prickly leaves, growing two or three feet high; from their centre a robuſt round ſtalk, ſupporting at top a large, oval, erect fruit, compoſed of numerous tubercles, and beautifully adorned at top with a crown of leaves, and blueiſh flowers, riſing ſingly from all the knobs or tubercles, and as the flowers fade the fruit enlarges, becomes a fleſhy ſubſtance, and as it ripens, aſſumes a golden colour, imparting a moſt fragrant odour.

Of the above ſpecies are ſeveral varieties, differing in the ſhape, ſize, and colour of their fruit, &c.

*The varieties of note are*] 1. Oval-ſhaped Pine-Apple with whitiſh fleſh, or Queen-Pine——2. Pyramidal, or Sugar-loaf Pine-Apple with yellow fleſh—3. Green Sugar-loaf Pine-Apple—4. Black Antigua, or Ripley Pine-Apple——5. Shining green-leaved Pine with ſcarce any ſpines, and with large fruit, or King Pine—6. Granada-Pine with marbled leaves and very large fruit—7. Bogwarp-Pine with broad green leaves——8. Smooth, long, narrow-leaved Pine——9. Gold-ſtriped-leaved Pine——10. Silver-ſtriped-leaved Pine.

Of the above varieties there are two principal ſorts in eſteem amongſt us in England, which are the two firſt-mentioned, viz. the Oval Pine-Apple, and the Pyramidal, or Sugar-loaf Pine-Apple, the latter of which is ſuperior to all the others in flavour, and is diſtinguiſhable by having the inner ſide of the leaves marked with purple ſtripes. Several of the other ſorts are alſo cultivated in many of our curious ſtoves, both for the ſake of the variety of their leaves, as well as that of their fruit, all of which attain due ſize, and ripen freely in our hot-houſes, though preference is generally allowed to the two firſt varieties. As to the two ſtriped-leafed kinds, i. e. the Gold-ſtriped Pine, and Silver-ſtriped ſort, are the moſt rare of any ſort in England, and are eſteemed principally for the ſingularity of their ſtriped leaves.

The four following ſpecies, not producing fruit of any conſideration, are only cultivated in ſome curious hot-houſes, for the ſake of variety.

[2]BROMELIA *Pinguin.*

*Pinguin, or Wild Ananas.*] Bromelia with many long, ſharp-pointed, prickly leaves from the bottom, and in the centre riſes an upright ſtalk a yard high, terminated by a cluſter of very ſmall fruit, reſembling a Pine-Apple.

[3]BROMELIA *Karatas.*

*Karatas, or Acaulis Wild-Pine.*] Bromelia with many very long narrow leaves from the bottom, ſtrongly armed with ſharp crooked thorns; and in the midſt of the leaves riſe a cluſter of fruits near the ground, each about four inches long, and one broad; ſomewhat reſembling the Pine-Apple.

[4]BROMELIA *Pyramidata.*

*Pyramidal Bromelia.*] Bromelia with many long, erect, aloe-like leaves, immediately from the root, ſharply indented and armed with thorns; and in the centre iſſues a ſtalk a yard high, adorned below with entire leaves, and above with flowers, forming a looſe ſpike, ſucceeded by ſmall oval fruit.

[5]BROMELIA *Lingulata.*

*Lingulated Bromelia.*] Bromelia with many erect leaves from the root, narrow at their baſe, widening gradually to the top, and with ſerrated ſpinous edges; and in the midſt of them the ſtalk, dividing into branches, ſuſtaining alternate ſpikes of cloſe-ſitting flowers, ſucceeded by ſmall, oval, pointed fruit.

Theſe

These four ſpecies are propagated by ſeed; alſo by ſuckers like the Ananas, and muſt always be kept in the ſtove.

*Culture of the firſt Species Bromelia Ananas, or Pine-Apple.*

The *Bromelia Ananas*, or Pine-Apple, and all its varieties, are herbaceous perennials of the evergreen kind, being perennial not only in root, but alſo in foliage, ſo may be ſaid to be herbaceous evergreens; and that being raiſed from ſeed, ſmall ſuckers, or the crown at top of the fruit, they, until arrived at a fruiting ſtate, conſiſt principally of an erect cluſter of long leaves ſtanding on the crown of the root, the whole plant encreaſing in ſubſtance and ſtature about two years, when they commonly produce ripe fruit, each plant one, appearing firſt in the centre of the leaves, generally in ſpring, crowning a robuſt ſtalk, which, as well as the fruit, grow perfectly erect, gradually advancing in height, and the fruit increaſing in magnitude till July, Auguſt, or September, then acquires maturity, obtaining in ſize, from about three or four to ſix or ſeven inches length, and three or four diameter, always crowned at top with a beautiful tuft of erect leaves called the crown, ſerving not only as an ornament to the fruit, but alſo for propagation; at the ſame time alſo of perfection of the fruit, the plants always emit ſuckers or off-ſets, for the like purpoſe of propagation, iſſuing both from between the leaves at bottom, and juſt under the baſe of the fruit, after which the old plants, becoming uſeleſs for fruit-bearing, may be preſerved as ſtools, to produce ſuckers; ſo that a ſucceſſion of young plants is always annually raiſed for fruiting, which is effected with great facility by the above-mentioned crowns and ſuckers: theſe being planted ſeparately in pots plunged in the bark-bed in the hot-houſe, &c as hereafter directed, where they ſoon ſtrike root and grow freely, or may even be ſtruck in a tan or dung hot-bed, made in a pit under a deep frame, or in hot-beds under a common cucumber or melon-frame, and afterwards removed to the ſtove to remain to come to perfection; though the plants are by ſome reared by the benefit of tan or dung hot-beds only, under a deep glaſs frame, hereafter deſcribed; but their culture is generally effected with greater facility and certainty in a hot-houſe, having the aid of bark-beds and occaſional fire-heat.

The appellation, Pine-Apple, given to this plant, is from the reſemblance of the figure of the fruit to the cone or fruit of the Pine-tree. See CONUS and PINUS.

This plant being a native of ſome of the hotteſt parts of Africa and South-America, in this country it requires the continual temperature of a hot-houſe, having the conſtant aid of bark hot-beds, &c. aſſiſted occaſionally in winter by actual fire, or in ſome ſuch glaſs departments, where we can employ ſuch artificial aids of heat, as ſufficiently to imitate the temperature of the native climate of this plant, which by many is now ſo well effected in our ſtoves, as to raiſe the fruit in almoſt as high a degree of perfection as it uſually attains in the above hot countries where it naturally grows.

It is raiſed in great abundance in moſt parts of the Britiſh Weſt-Indies, and moſt other of the hot parts of America, where the plant grows freely at all times in the open ground, and from which country we were formerly ſupplyed with many young plants; but our hot-houſes being now plentifully ſtocked with them, furniſh conſiderably better plants than any procured from thence; for thoſe we receive from that country are often collected from good and bad ſorts indifferently, and theſe frequently almoſt periſhed through the length of the voyage and ill-management; ſo that the practice now of procuring plants from ſo great a diſtance is hardly worth the trouble, unleſs for the ſake of ſome valuable new variety that ſhall happen to be diſcovered.

Holland was the firſt European country where the culture of this plant was attempted, and the temperature of heat diſcovered to bring it to a proper fruiting ſtate, and from which country we here in England were ſupplied with the firſt plants and hints for its culture, in which we have ſo greatly improved as to equal, if not excel, all other countries of Europe.

The principal ſeaſon of obtaining this fruit in perfection in England is from June until October, they generally ſhewing fruit in February or March, which advances gradually to perfection, acquiring maturity at different times, for the fruit of the ſame time of appearance are often a month or ſix weeks difference in their times of ripening; but the time of their greateſt perfection is Auguſt and September, though ſome plants being ſo backward in ſhewing fruit, that it ripens ſtragglingly in winter, and even ſome not until ſpring;

ſpring; but their flavour is inferior to that ripened at the afore-mentioned times; ſo that in their culture we ought to promote their ſhewing fruit only in ſpring, that they may have the ſummer to effect their growth, by which they will obtain their due ſubſtance, beauty, and deliciouſneſs of flavour.

*Of the Hot-houſe or Stoves, &c. wherein to raiſe them.*

Having before obſerved, that to cultivate theſe plants in England, or any part of Europe, they require the conſtant accommodation of hot-houſes; with reſpect therefore to theſe departments, requiſite particularly for theſe plants, it is further neceſſary to remark, that to effect their culture more commodiouſly, and ſo as to be well ſupplied with proper fruiting plants annually, it is proper to be furniſhed with two orders of ſuch hot-houſes or ſtoves; a ſmaller one to raiſe the plants, and a larger one to fruit them, each having a cavity or pit within-ſide the whole length, ſix or eight feet wide, and three deep, wherein to make the bark-bed, i. e. a hot bed formed of tanner's-bark, in which to plunge the pots containing the plants; for this kind of hot-bed is moſt neceſſary in the culture of pines, and each of which departments to be alſo provided with flues, in which to make occaſional fires in winter. See HOT-HOUSE.

The former of theſe departments, i. e. the ſmaller ſtove, is by gardeners ſometimes called the pit, ſee BARK-PIT; or if of a more capacious dimenſion, the ſucceſſion-houſe; and its uſe is by way of a nurſery-ſtove to the main ſtove or fruiting-houſe, it being deſigned ſolely for the reception and rearing the young plants, that is, the crowns and ſuckers beforementioned, which being planted ſingly in ſmall pots in autumn, as hereafter directed, are plunged in the bark-bed of this ſmall ſtove, to remain about a year, or until they attain a proper ſize and ſubſtance for fruiting, without encumbering or taking up the room in the principal fruiting-ſtove juſt-mentioned, by which means you will be able to fruit many more plants therein, than if the young and old were crowded together in the ſame department; beſides, you can regulate the heat in this nurſery-ſtove as the plants ſhall require, for they muſt not be much forced in their infant ſtate, leſt it drive them unſeaſonably into fruit, which, if it happens when the plants are leſs than fifteen or eighteen months old, the fruit, beſides coming at an untimely ſeaſon, will be ſmall and trifling; ſo that the intention is to rear the plants in this nurſery-ſtove till they are a year or two old, when they will be nearly full-grown, or, at leaſt, moſt of them will have acquired ſuch ſize and ſtrength, as to be capable of producing tolerably large fruit, and are then to be removed in autumn in their pots to the main or fruiting-ſtove.

And as to the fruiting-ſtove juſt mentioned, it is intended principally for fruiting the plants, after being reared from crowns and ſuckers in the nurſery pit or ſucceſſion-ſtove a year or two, till they obtain the ſize or bearing ſtate above-mentioned, which being removed in their pots the beginning or middle of October to this main or fruiting-ſtove, and plunged in the bark-bed thereof, where, by the management hereafter directed, they commonly ſhew fruit the ſpring following, and which gradually arrive to perfection the enſuing ſummer and autumn.

For the proper dimenſions of each of theſe ſtoves or hot-houſes, ſee HOT-HOUSE, BARK-PIT, &c.

But where large quantities of theſe plants are cultivated, many, beſides the above-mentioned ſtove departments, have alſo what is commonly called a bark-pit, formed by a deep frame of wood, or of brick-work ſix feet wide, the length at pleaſure, five or ſix feet deep behind, and four and half in front, having the top glazed, ſee BARK-PIT; and is deſigned principally wherein to make a bark or dung hot-bed, for the immediate reception of the crowns and ſuckers from the parent-plants, as an eaſe to the ſucceſſion-ſtove, by not crowding it too much, which is often at that time entirely filled with large ſucceſſion-plants for next year's fruiting; but, by the time the crowns, &c. in this pit have ſtruck root and begin to grow, the ſucceſſion-ſtove will be thinned of the largeſt plants, to furniſh the fruiting-houſe, which is generally in October, when the ſuckers and crowns in their pots may be removed to the ſucceſſion-ſtove; though when that department is ſtill crowded with larger plants, theſe ſmall ones of the ſame year are often continued in the bark-pit all winter, or longer, if neceſſary, eſpecially if the walls which form it are of brick, having flues on the back for fires, or even, if it is entirely of wood, the temperature of heat may be continued by the aid of ſtrong dung linings againſt the outſides of the back of the frame, for it is alſo very poſſible

to

to ſtrike the crowns and ſuckers, as above-noticed, by the aid of dung hot-beds only, either in the above bark-pit, or under common cucumber or melon frames, covering the top of the dung with tan, wherein to plunge the pots containing the plants.

It is alſo even practicable to rear and bring theſe plants to produce ripe fruit by the benefit of dung-heat only, under deep frames, hereafter deſcribed, which, however, though attended with conſiderably leſs expence, requires more trouble, and the ſucceſs never ſo certain nor equal to that of proper ſtoves, aided by bark hot-beds and fires in winter.

Crowns and ſuckers, however, as already obſerved, immediately from the parent-plant, may be readily ſtruck and ſet to growing in tan or dung hot-beds without fire, under common garden-frames and glaſſes, and even if the bed is compoſed of dung, with tan at top, wherein to plunge the pots of plants, they, by the aid of two new beds, with occaſional ſtrong dung linings, might be continued there all winter, or, by the additional aid of a more capacious frame, in width and depth adapted to the height of the plants, they might be carried on to a due ſize for the fruiting-ſtove. See *Raiſing them without Fire.*

In many places, however, the whole culture of theſe plants is performed by the aid of one ſtove only, not having the convenience either of a ſucceſſion-ſtove or nurſery-pit, and the plants are raiſed and fruited all in the ſame department, though by this practice not above one half of the hot-houſe can be commodiouſly occupied at one time with fruiting-plants, the other half muſt conſequently be employed in containing the ſucceſſion-plants, and crowns and ſuckers, unleſs you fill the whole pit of the ſtove with the fruiting-plants, ſo crowd the pots of young ones in between them, as frequently practiſed; however, at any rate, when the young plants are raiſed in the ſame ſtove with thoſe that are fruiting, and that we keep the ſtove in a due temperature to fruit them in full perfection, there is no certainty of keeping your crowns and ſuckers, and the ſucceſſion-plants in general, from running to fruit unſeaſonably in their infant or half-grown ſtate; hence the neceſſity is apparent of having a ſmall ſtove ſolely for theſe young plants, or, at leaſt, a bark-pit, or deep frame, which we above obſerved.

However, the moſt commodious and certain culture of this curious plant and fruit is, by the convenience of two orders of ſtoves, at leaſt, as we at firſt adviſed, having the conſtant aid of bark hot-beds.

*Of the Tanner's-bark for the Bark-bed.*

In regard to the tanner's-bark for the bark-bed, we formerly obſerved, that each of the above ſtove departments, &c. ſhould have a pit or cavity formed within-ſide the whole length, wherein to make a hot-bed of tanner's-bark, in which to plunge the pots of plants, and which is commonly called the bark-bed; this kind of hot-bed is compoſed entirely of tanner's-bark, which being of ſuch an agreeably moderate, durable, and nouriſhing heat to theſe plants, that without it we cannot bring them with certainty to fruit in any tolerable perfection; for fire-heat alone will not anſwer the purpoſe, as it dries and hardens the extreme fibres, and the plants become ſtunted, producing ſmall ill-nouriſhed fruit, ripening unſeaſonably late; whereas, by plunging the plants in the above hot-bed, the conſtant moiſt warmth it imparts to the mould and roots is excellently well adapted to the nouriſhment and growth of the plants and fruit: and that of the tanner's-bark is preferable to any compoſt of dung hot-beds for this purpoſe, and being alſo not only of three times longer duration in its heat, it never, like dung hot-beds, ſends up noxious ſteams; and as to duration, the ſame bed with a little aſſiſtance, will ſupport a growing temperature almoſt a year.

In reſpect to the time of duration juſt mentioned of the bark-bed, obſerve, it is commonly made in autumn, i. e. September or October, that it may be in good condition all winter, and it upholds a fine growing heat about four months, which, if then forked up to the bottom, renews its fermentation, and continues two or three months longer; then if in April you add about one third of new tan, the whole being again forked up to the bottom and mixed together, revives the heat ſubſtantially, and continues it in fine order till towards autumn, and by September and October it will be conſiderably exhauſted, when the whole muſt be ſcreened, and all the ſmall earthy ſubſtance cleared away, levelling the larger in the bottom of the pit, and a large quantity of new is then to be procured from the tanner's, to fill it up again to the proper height, three or four inches above the kirb, to allow for ſettling; at the ſame time ſtir up and mix the old and new together, and this work of ſcreening the old, and renewing

renewing the pit with fresh bark at the above time in autumn, is to be practised annually to each bark-bed.

For the choice of the bark, and some other particulars relative to this material, see BARK-BED.

*Of the proper Soil for the Plants.*

In respect to soil proper for the growth of those plants, they prosper freely in any rich, moderately light garden-mould, such as that of the kitchen-ground, where it is of a rich, fat, pliable temperature, and if somewhat of a loamy nature, of mellow texture, it will be an advantage, for nothing heavy, very wet, or stubborn, must be admitted; this mould may be got in readiness in a heap several months before-hand, adding thereto, if necessary, some thoroughly rotten dung; and if the soil is very light, it is proper to add about one half or a third part of fine pliable loam from the surface of a common or other pasture-ground, turning the whole over several times.

Or a compost may be prepared thus:

Procure from a rich pasture-field, or common, some mellow loamy earth, taking the top spit, not digging it out of deep pits, which is harsh and sour; to every load of this add about one third or fourth-part of a load of perfectly rotted dung of an old dung hot-bed; mix these well together, and form the whole in a ridge or long heap in the full air, in a sunny exposure, to lie at least six, but if ten or twelve months, or more, the better, turning the whole several times, that the parts may be properly incorporated, and receive equal benefit of the sun and free air; at each time of turning break all turfy lumps and clods, and when it is to be used break it fine with the spade, but not sift or screen any, which would render it too compact.

Of these composts it is proper to provide as much at first as will serve two or three years, since by lying together it will be much improved for the purpose intended, provided it is turned over three or four times annually.

Be careful never to use the earth at any time too wet.

*General Method of Propagation.*

As to the propagation of this plant, all the varieties, as before noticed, are propagated with great facility by the off-sets or suckers issuing from the lower part of the plant and base of the fruit, as well as by the crown or leafy tuft that decorate the top of it, all of which suckers, off-sets, and crowns, though devoid of roots when separated from the plant, that being planted singly in small pots of light rich compost, plunged in the bark hot-bed in the stove, &c. as hereafter directed, readily emit fibres, and grow freely, and, as already noticed, they, after two, or, at most, three years growth, produce ripe fruit, equal in size and quality to that of their respective parent-plants, observing that the same individual plant produces fruit but once; so that after they have fruited and produced a supply of suckers for encrease, which is commonly at the time of fruiting, they are good for little afterwards, except as stools to produce a few more suckers; hence it is apparent the necessity there is of raising an annual succession of fresh plants for fruiting, by the above means of suckers and crowns.

Each plant generally yields from two or three to five or six suckers at a time, but rarely more than one crown upon each fruit.

The season for propagating, both by suckers and crowns, is according to the time the plants and fruit produce them, which is principally July, August, and September, according as the fruit ripens, though the plants will grow at almost any time, observing, however, that both suckers and crowns are always fit to be taken off for propagation when the fruit is ripe, and not sooner; and as to the suckers, it is a sign of perfection when they appear brownish at bottom; they are to be slipped or drawn off carefully with the hand, not cut; the crown at top of the fruit is to be taken off also with a gentle twist; but this latter is not to be done till the fruit is served at table. When they are taken off, both the suckers and crowns should be divested of a few of the lower leaves at the bottom, where they are to strike root, then laid or hung up in a dry part of the house or stove four or five days, that the wound or moist part of the base, where they adhered to the plant or fruit, may heal and dry up before they are planted, otherwise they would be apt to rot; but in some of the stools you will often find suckers which assume a brown colour at the bottom, as above hinted, and forming little knobs round the edge, which are the embrios of future roots; these suckers being ripe, or having had their full growth on the mother-plant, do not require to be so much dried as those which appear greener, and may even be planted directly, or, at least, taken off one day and planted the next; but the crowns of those fruit which do

not ripen till late in September or October, require to be dried more than thoſe beforementioned, and if ſuckers of thoſe plants that produce their fruit later do not appear brownish at bottom, it is adviſeable to ſuffer them to remain upon the ſtools till March following, for they are very apt to rot at bottom, not only when taken off very ſucculent, but alſo when taken off later than October.

We have commonly the greateſt quantity of crowns and ſuckers from the beginning of Auguſt to the middle of September.

As to the mother-plants or old ſtools, if you are diſpoſed to have as great an encreaſe of young plants as poſſible, the ſtool, after the fruit is gathered, and the ſuckers taken off, may be trimmed, i. e. cut down all the leaves near the bottom, and then plunge the pots directly in a hot-bed of tan or dung under frame and glaſſes, and let them be duly watered, they will ſoon after produce another ſupply of ſuckers, though thoſe of the firſt production are rather preferable.

Likewiſe in caſes, when the plants produce ripe fruit and no ſuckers from the bottom at that time, as ſoon as the fruit is cut, trim the leaves of the old ſtools, as above directed, and plunge them in a hot-bed of briſk heat; it will diſpoſe them ſoon to ſend forth ſeveral ſuckers.

*Method of planting, and their Management in the Nurſery ſtove, &c.*

To proceed to the manner of planting the crowns and ſuckers, and general culture the firſt year, to prepare them for the fruiting-ſtove, obſerve as follows.

Having the bark pit in the nurſery-ſtove or frame, &c. filled with bark, ſee BARK-BEDS, and of a proper briſk temperature of heat, for the reception of crowns, as they are taken immediately from the mother-plant, at the times and manner above-mentioned, and having the proper compoſt in which to plant them, pots, and every other requiſite in readineſs as they ſhall be wanted, theſe young plants then, according as they are fit to be taken from the parent-plant, are to be planted ſingly in ſmall pots of the ſize called forty-eighths, ſee POTS, which, at the time of planting, are to be filled with the aforeſaid compoſt or mould, taking previous care to put a ſhell or piece of tile over the hole at bottom of each pot, to keep the mould hollow, that the water given the plants may paſs off freely; the pots being thus filled, one plant, i. e. crown or ſucker, is to be planted in each pot, in doing of which, be cautious not to plant them too deep, for the earth to get between their leaves, neither ſhould they be planted too ſhallow, for ſo they would be liable to be diſplaced by watering, or doing any other neceſſary culture, obſerving to preſs the earth cloſe about each plant.

According as the plants are thus potted, they are to be directly plunged in the bark-bed of your ſucceſſion-ſtove or nurſery-frame, &c. above deſcribed, obſerving that the bed be previouſly arrived to a due degree of moderate heat, and in which the plants are to be arranged according to their different ſizes, placing the largeſt next the back-part, and the ſmaller in front, and the others in proportion; that being thus regularly diſpoſed, it will add to the beauty of them, and every ſingle plant will more eaſily receive an equal benefit of the ſun, being careful to plunge each pot up to the rim in the bark.

As ſoon as they are plunged give them a gentle watering, and, if the weather is ſunny and hot, ſhade them moderately in the heat of the day, till they are firmly rooted.

Having thus planted and plunged the plants in the bark-bed, &c. they will in a week or two ſtrike root and begin to grow, when air muſt be pretty freely admitted; for at this period it is adviſeable to promote but a moderate temperature of heat, that is, not to encreaſe it conſiderably by keeping the ſtove or frame too cloſe while the heat of the bark-bed is ſtrong, which would not only draw up a vehement heat in the bed at firſt, and force the young plants too much in growth, but, by being too cloſely confined, would draw them up weak, with long, feeble, whitiſh, ſickly leaves: freſh air muſt therefore, at this time, be daily admitted, at leaſt at all opportunities, when the days are hot and calm, by ſhoving or tilting the glaſſes a little open, which muſt always be proportioned in a judicious manner, for there are no preciſe rules to be given for it; but by making uſe of your own obſervation and experience, added to theſe directions, you will ſoon attain a due knowledge in this point. From about nine or ten, to four or five o'clock, is the proper time of day for the admiſſion of air.

Waterings alſo is requiſite, though very moderately, about once a week, eſpecially until the plants begin to grow, when they may be watered more freely, which in fine warm weather ſhould be ſprinkled all over their leaves.

As

As the winter advances, be careful that the bark-bed, wherein theſe young plants are now plunged, uphold a conſtant temperature of heat, which is readily promoted by forking up the bark once or twice during this ſeaſon, according as the heat ſhall decline; likewiſe keep the internal air of due temperature, by the aid of occaſional moderate fires on nights, provided the department is furniſhed with flues, or, in default of which, by linings of hot dung againſt the outſides: freſh air muſt alſo be admitted from without judiciouſly, at all favourable opportunities, in ſunny calm days, by ſliding or tilting ſome of the glaſſes or ſaſhes a little open; and moderate waterings is neceſſary about once a week, eſpecially if the plants are in a ſtove or pit where fires are made; in other caſes it muſt be applied ſeldomer, and very ſparingly.

In reſpect to the bark bed, it generally ſupports a good temperament of heat till January or February, when, if the heat is found much abated, take up all the pots, and with a fork ſtir up the bark, as before obſerved, quite to the bottom, plunging the pots again directly, and this will promote a freſh fermentation, and greatly revive the heat, ſo as to maintain a due temperature the remainder of the winter.

And as to the fire-heat above-noticed, for warming the internal air, obſerve, that, if the plants are in the nurſery ſtove or ſucceſſion-houſe, or any other department, having flues for making fires, it is proper to begin to make moderate ones on nights towards the middle of November, or a little ſooner or later, as the froſt or other very cold or dark foggy weather ſhall render it neceſſary, being cautious never to make the fires too ſtrong for theſe young plants, leſt, by occaſioning them to ſhoot too faſt, it force them into trifling fruit the ſame winter, or enſuing ſpring or ſummer, which would be a great diſappointment in reſpect to having proper-ſized plants at the due time for the fruiting-ſtove; for if once theſe young plants draw up with long leaves, appearing white at heart, it is generally the ſigns of a too forward growth, and the conſequence of their untimely fruiting; therefore never be too eager in forwarding their growth at this ſeaſon.

In ſevere weather the glaſſes of the ſtove ſhould be defended on nights with the proper covers, either of thick canvas, oil-cloths, or tarpaulin, let down by a roll and pullies, or by ſhutters or mats.

Where theſe young plants are wintered in any detached bark-pit, or any kind of frame devoid of flues for having fires, I adviſe, in this caſe, when the winter advances, that the pit or deep frame, wherein the bark-bed is made, be lined around on the outſide with hot dung, as practiſed to cucumber or melon-beds, quite from the bottom to the height of the internal bark-bed: on top of the lining lay old hay, fern, or other ſimilar dry litter, continuing either of which materials from the top of the lining to that of the frame all around, which will preſerve the heat of the linings the longer, and prevent the froſt from penetrating the ſides of the frame, obſerving, that when the lining declines its heat, remove the litter, and add a ſufficient quantity of freſh dung on top of the former to the height of the frame; or, if the heat is conſiderably abated, ſtir up the whole with a fork, old and new together, to the above height, which will renew the heat quite from the bottom; and this ſtirring or turning over the linings, with the occaſional addition of freſh dung, in lieu of ſuch that becomes exhauſted, is to be repeated as often as it ſhall appear neceſſary during the winter or continuance of cold weather, which will not only communicate its heat to the bark-bed, but aſſiſt greatly in warming the internal air of the frame, obſerving alſo to cover the glaſſes every night and ſevere weather, and give but very little water to the plants in this department during winter.

Having in either of the above departments conducted the plants ſafe through the winter, it now remains to give directions concerning their ſpring culture.

As to their ſpring culture, the neceſſary care of preſerving heat in the bed, and internal air, with the aids of freſh air and water, as already directed, is ſtill to be obſerved with ſtrict attention; for it is of importance to remark, that from the month of March until September, is the principal growing ſeaſon of theſe plants, ſo muſt begin to encourage it as much as poſſible, though by no means force them; but that when there is a good heat in the bed, indulge them freely with freſh air, and refreſhments of water, by the rules already laid down, and hereafter directed.

At this ſeaſon the plants, for one thing, require their firſt ſhifting into pots a ſize larger, and the bark-bed to be ſtirred up again, and refreſhed with about one third of new tan.

This firſt ſhifting may be performed any time in April, though about the middle of that month is a very good time for that work, and the proper ſized pots are thoſe called thirty-twos, ſee POTS. The proper time being arrived, and the pots and proper quantity of compoſt mould brought ready, proceed to take up the plants out of the bark-bed, and turn each ſingly out of its preſent pot, with the ball of earth entire around its roots, unleſs any appear very unhealthy, or any ways defective, when it is eligible to ſhake the earth from the roots, and trim off all the long fibres and other parts that appear not alive; alſo decayed leaves on the plants in general muſt be ſtripped off, not cut, then, having put a piece of tyle or oyſter-ſhell over the holes at bottom of each pot, put in a little freſh compoſt, and on this place your plant, and fill up around the ball or root with more new mould almoſt to the brim of the pot, preſſing the earth moderately firm about the body of the plant; and when the whole is thus ſhifted, directly prepare to plunge them again in the ſame bed; previous to which obſerve, as above, to add about one third, at leaſt, of new tan to the old, or as much as will ſufficiently raiſe the bed as much as it has ſunk ſince autumn, previouſly clearing away any very crumbly or exhauſted earthy ſtuff at top or outſides; then, having filled up the pit to the uſual height with the new bark, immediately proceed to work the whole, old and new up together, with a fork, ſee BARK-BED, and directly plunge the plants as before, the talleſt at back, continuing the loweſt gradually to the front; and as ſoon as the whole is thus plunged, give a moderate watering all over the leaves and mould of the pots, to cleanſe the plants, and ſettle the new earth cloſe about their roots.

The plants having thus had their firſt ſhifting, and the bark-bed its ſpring renewal by a little new tan and freſh forking up, the principal future culture during ſummer is the neceſſary ſupply of freſh air and water; for the bark-bed will now maintain a proper heat till towards autumn, or time the plants require ſhifting again.

As the ſummer comes on, the plants muſt be indulged more freely with air and water; air muſt be admitted every day, whenſoever the weather permits, by opening ſome of the lights, more or leſs, which ſhould be done the moſt freely when the days are ſunny and the wind quiet, and in July and Auguſt, if the weather is very hot, the plants ſhould be permitted to enjoy a very large ſhare air, even ſo much as to be ſometimes almoſt fully expoſed in the middle of ſuch days; for as they will now grow freely, if they are too cloſely confined they will draw up long and tender, and become feeble and leſs able to produce fruit in full perfection of ſize and flavour; and likewiſe, by too cloſe confinement in ſummer, they will be in danger of going into fruit early in winter. Water during this ſeaſon in warm ſunny weather is neceſſary, in moderate quantities about twice a week, applying it in a morning until June; and during the hot months of June, July, and Auguſt, an evening is the moſt eligible time, ſprinkling the water occaſionally all over their leaves; which works of admitting freſh air, and giving water, is the principal culture neceſſary to theſe plants in ſummer, until the time of their ſecond ſhifting into larger pots in Auguſt.

Obſerve, however, if the bark-bed is much crowded with plants, and that by the beginning of July they have advanced conſiderably in growth, it would be of much advantage to remove ſome of the ſmalleſt plants in their pots into a bark-bed, under any common frame, till October; ſo re-plunge the larger ones at a more eligible diſtance in their preſent department, which is the moſt neceſſary culture to encourage them to bottom well.

In regard to their ſecond ſhifting, the plants in general will require it in Auguſt, at which time a quantity of the ſtrongeſt plants are to be ſhifted into proper ſized pots, wherein they are finally to remain to produce their fruit.

This ſecond ſhifting is to be performed about the beginning or middle of Auguſt; the pots proper for their reception now is called twenty-fours, but not larger than ſixteens for the ſtouteſt plants: in the execution of this work obſerve to turn the plants out of their preſent pots with the balls of earth entire about their roots, and may carefully trim off a little of the outſide mould, as alſo ſome of the extreme fibres of the roots on the outſide of the ball, ſtill preſerving the ball of earth about them; then having tiled or ſhelled the holes of the new pots, and put ſome freſh earth at bottom, to raiſe the plant to its due height, place the plant thereon, and fill up the pot around the ball with more compoſt almoſt to the top, and when they are all ſhifted, ſtir up the bark-bed to enliven the heat, and inſtantly plunge the pots again in the order of arrangement before directed, and

give

give a moderate watering all over the plants: here they may remain ſix weeks or two months, or longer; for if the bark-bed at this time of ſhifting is well forked up to the bottom, it will uphold a heat proper to ſupport the plants in a growing ſtate till October, when moſt of them will have obtained a large ſize, and the fruiting-ſtove is to be got ready for the reception of the largeſt that appear capable of fruiting in perfection the enſuing year: in the mean time be careful, after this ſecond ſhifting, to continue the admiſſion of a due portion of freſh air daily, to ſtrengthen their growth, to diſpoſe them to produce handſome fruit at the due time; ſupplying them alſo with gentle refreſhments of water once or twice a week, according to the temperature of the ſeaſon.

*Removing them to the Fruiting-ſtove, and Culture there.*

Towards the end of September the above plants in the nurſery-ſtove or ſucceſſion department will be grown to a conſiderable ſize, when the fruiting-ſtove, &c. muſt be got ready, and its bark-pit filled with entire freſh tan, for the reception of the largeſt plants; and ſuch as have not yet acquired due ſtrength for fruiting in perfection next year, may be permitted to have another year's growth in the ſucceſſion-ſtove.

If the fruiting ſtove is now occupied with plants in fruit, the ſucceſſion-plants cannot be moved thither till the fruit is moſtly all cut, which for the general part is pretty well cleared by October or beginning of November, at which time a ſufficient quantity of freſh bark or tan muſt be procured from the tanner's to fill the bark-pit of this ſtove, for the bark bed muſt be always renewed annually almoſt entirely with freſh tan at this ſeaſon, at ſame time previouſly ſcreening all the old tan to ſeparate the larger from the ſmall exhauſted parts, and all the ſmall earthy ſtuff that paſſes through the ſcreen taken away, and levelling the other along the bottom, provide as much new tan as, with this, will fill up the pit to the proper height.

As to the choice of the new bark, it ſhould be freſh, i. e. having been but ſhortly thrown out of the tan-vats, and rather large than ſmall, for the latter ſoon becomes earthy, and loſes its fermentation: when it is brought from the tanner's, it is frequently wet and unfit for immediate uſe; let it therefore be ſpread on level ground to dry a day or two, then either caſt it in an heap to acquire a proper warmth, or put it immediately into its deſtined pit in the ſtove, upon the remaining old tan, raiſing it three or four inches higher than the kirb at top, to allow for ſettling, forking up the old and new together, ſo ſuffering the whole to remain a week or ten days, to acquire a due temperature for the reception of the plants from the ſucceſſion-ſtove; for they muſt not be plunged in it before it is capable of imparting a proper warmth to the mould in the pots.

Having thus prepared the pit of this ſtove, as above, with good freſh bark, and it has obtained the due degree of heat, then immediately bring your largeſt plants from the ſucceſſion-ſtove in their pots, and plunge them with the ſame regularity I before adviſed, and allow them room, that they may bottom well, for this is of importance in reſpect to their producing large fruit: the plants being plunged, it is proper the next day, or as ſoon as the bed has communicated a proper warmth to the earth in the pots, to give them a moderate watering, both to the pots and all over the leaves, which will be a conſiderable refreſhment to the plants.

They being now placed in the fruiting-ſtove are called fruiting plants.

Their culture in this department, i. e. the fruiting-ſtove, differs little from that in their former repoſitory.

All winter the internal air of the ſtove muſt be ſufficiently ſupported by the aid of fires on nights, and ſevere froſty weather. As to the heat of the bark-bed, it will ſupport a due temperature till February, when forking it over will revive it for two months longer. Freſh air during this ſeaſon muſt ſtill be admitted with diſcretion at favourable occaſions in ſunny mild days, and moderate waterings will be needful about once a week.

With reſpect to the time to begin to make the fires, is ſome time in November, either ſooner or later in that month, according as the cold advances, for we muſt be very careful to obſerve this as ſoon as ſevere or very foggy or cold wet weather renders it neceſſary; but unleſs ſevere froſts happen, gentle fires only on nights ſhould be made until the beginning of January, when they ſhould be gradually encreaſed more briſker, in order to prepare the plants for ſhewing their fruit in February or beginning of March, being always careful to regulate your winter's heat by the thermometer, ſee THERMOMETER; obſerving the fires

are

to be made principally on nights, except in ſevere or very wet or foggy damp weather, then it is proper to continue them alſo moderately in a morning.

In very ſevere weather it is alſo eligible to cover the glaſſes on nights with ſuch covers as the ſtove is furniſhed, either by large thick canvas cloths or tarpaulins on rolls, to let down and up by pullies; or with large mats, or ſhutters; but the firſt-mentioned is the moſt ready covering for the top glaſſes, ſee HOT-HOUSE; though many uſe no other covering for their ſtoves, where fires can be made, than nailing ſtrong mats at top on nights in very ſevere weather; alſo occaſionally againſt the front and end glaſſes.

During this ſeaſon give air diſcretionally in fine mild ſunny days, from ten till about three o'clock, as favourable opportunities ſhall then offer

Give alſo moderate waterings about once a week, and not much over their leaves at this time of year, uſing the tin pipe hereafter mentioned.

Towards ſpring, when the plants begin to ſhew fruit, be ſtill careful to promote a due degree of heat in the bark-bed, and continue the fires regularly on nights, and give air and neceſſary waterings. If, in January or February, as above hinted, the bark-bed decreaſes much in its heat, fork it up, as directed for the ſucceſſion-plants, which will renew the fermentation, and continue it in fine order until April, when a little new tan muſt be added, and the whole again well ſtirred up together to the bottom.

In the beginning of April therefore, prepare to add ſome new tan, and ſtir up the bark-bed again, to promote ſuch a durable heat as will carry the plants through the ſummer, and till the maturity of the fruit now advancing in growth: to do this the more effectually, provide about one third of the pit full, or a little more or leſs, of new tan, prepared, as before, in making the bed; and after taking up all the pots of plants, throw this in upon the old tan, filling up the pit to the full height, then fork the whole up to the bottom, mixing the old and new well together; this done, level the top, and directly re-plunge the plants, and the effect of this operation will ſoon appear in the growth of the fruit; for after this fruit begins to advance, it is good culture to promote a good heat in the bed, as well as ſufficiently to preſerve a conſtant and proper temperature of internal air, according to the degrees of heat marked on the thermometer, that you may more freely apply the neceſſary aids of freſh air and water; and that by proportioning heat, air, and water, depends the whole ſucceſs of having large and well-flavoured Pine-Apples.

One caution in reſpect to watering is, that after the fruit begins to appear, I adviſe not to water too freely over the leaves, but more eſpecially when they are in bloom, leſt you waſh off the farina of the antheræ, before it has ſufficiently performed its fecundating function, and thereby prevent ſome of the knobs or tubercles from ſwelling in a due manner, which would render the fruit unſightly; therefore, in watering at this period of their growth, it is proper to uſe the tin pipe hreafter mentioned, which is alſo very convenient for watering at all other times, and more eſpecially in winter, when the plants ſhould never be ſo much wetted as to occaſion water to ſtand in their hearts.

As the ſummer and warm weather advances, gradually decreaſe the ſtrength and uſe of fire heat, and by degrees uſe it only occaſionally, ſo as to leave it wholly off in May.

Continue during ſummer to admit freſh air daily into the ſtove, by ſliding the front or top lights more or leſs open, according to the power of the ſun's heat, ſtill obſerving, that from about eight or nine in the morning; till four or five in the evening, is the proper time for doing this: alſo continue to give water freely all ſummer, about twice a week, at leaſt, in hot weather, performing it either in a morning or an evening, which, after the bloſſom of the fruit is paſt, and it advances in magnitude, may be given in occaſional refreſhments all over their leaves, as this will promote a lively appearance in the plants, and encourage the free growth of the advancing fruit; for the heat of the bark-bed being promoted by the means adviſed to be practiſed in April, if you are careful during the hot weather to indulge the plants freely with freſh air and refreſhments of water, agreeable to the preceding rules, the fruit will encreaſe freely in bulk, and advance faſt to perfection, ſo as thoſe which appeared early in ſpring will probably arrive to maturity in June or July.

They, however, in reſpect to the times of ripening, generally come dropping in from June or July to October or November, but are commonly in greateſt perfection in Auguſt and September.

The

The firſt ſign of perfection in moſt ſorts is, their aſſuming a ſingularly beautiful golden yellow, though ſome diſcover different tints peculiar to them; but the moſt certain ſign of full growth and ripeneſs in this fruit, is its delightful fragrance: obſerve therefore theſe tokens of perfection, and let the fruit be gathered before it becomes ſoft; for it would then be greatly diminiſhed in its perfume and delicate poignancy of flavour.

The manner of gathering this fruit is, to cut it from the plant with ſeveral inches of the ſtalk, preſerving alſo its crown of leaves at top.

To have it eat in the higheſt perfection of flavour, it ſhould be cut in a morning before nine o'clock, and laid in a cool dry place till dinner-time, or till wanted, but its juice is always more poignant and rich when eaten the ſame or next day, though they will keep a week or longer, if required upon any particular occaſion.

It is always ſerved to table with its crown of leaves on, and when the fruit is to be eaten, the crown is twiſted off and reſerved for planting, to become a new plant, which, in its turn, produces a freſh fruit, as well as ſuckers, for future propagation.

If too many of theſe fruit are like to arrive to maturity together, their ripening may be retarded by removing ſome of them to one end of the ſtove by themſelves, and ſo ſhade the glaſſes with mats in ſunny days.

As to the old plants, after the fruit is gathered, they bear no more, ſo are only fit for ſtools to produce ſuckers, having their leaves trimmed down cloſe, and plunged in the bark-bed, or any other briſk hot-bed, as we have before directed.

*Neceſſary Obſervations.*

In reſpect to the tin pipe before recommended to be uſed occaſionally in watering theſe plants, it is extremely uſeful and convenient, for the more ready conducting the water, in the quantity intended, to any particular plant in any part of the bark bed: its dimenſions may be ſix feet long, an inch and half diameter at the upper end, the other about half an inch, though it may be of two different joints to lengthen or ſhorten at pleaſure; at the largeſt end ſhould be a kind of funnel, either fixed, or to take off and on occaſionally, to receive the water from a watering pot. By the aſſiſtance of ſuch a pipe, the water is readily conveyed to all the plants ſeparately in any quantity, without pouring any into the hearts of them when not intended, or without wetting the bark-bed more than what is neceſſarily applied to moiſten the earth in the pots, &c. This pipe ſhould be particularly uſed in winter; alſo occaſionally in ſpring during the bloom of the fruit.

Soft water ſhould always be uſed for watering theſe plants, either that of a river, pond, or rain water, being careful in applying this article never to give it in too great quantities, to wet the mould conſiderably, eſpecially in winter.

In winter it is proper to have a ciſtern, or ſome other conveniency placed in the ſtove to contain water, that the chill may be a little taken off previous to watering the plants therewith.

With regard to the fuel for making the fires in the ſtoves, ſeveral ſorts are uſed.

The beſt fuel for this uſe is coal, which makes the moſt ardent, regular, and durable fires of any other materials whatever, and therefore, where it can be obtained at a moderate expence, I ſhould particularly recommend it for this purpoſe: but, in default of coal, wood is next to be preferred, and the larger the principal part is, the better for the duration of the fires. Next to wood is ground-peat and turf, but theſe are ſoon exhauſted, unleſs the fire-place is purpoſely conſtructed, ſee HOT-HOUSE. There is a ſort of fuel by ſome uſed, to be had at the tan-yards, made of old tan, &c. into ſquare lumps, which is alſo called peat; but all theſe are inferior to coal, though, where this article is ſcarce, one or other of theſe muſt ſuffice.

It is to be obſerved, the fires in each department are to be made chiefly from November until April or beginning of May, and ſhould be made every evening about four, five, or ſix o'clock, which ſhould be attended twice or thrice till bed-time, ſo as to warm the flues ſufficiently to ſupport a due temperature in the air of the ſtove till morning, when, in very ſevere froſt, and very wet or foggy damp weather, a moderate fire ſhould alſo be made, but in mild dry weather none is neceſſary at that time of day.

To regulate you in regard to the ſtrength of the fires, and proper times to make them, it is proper to have a good thermometer always hung up in the middle of the ſtove, having the proper degrees of heat marked *Ananas*, never permitting it to be more than five or ſix degrees above, nor leſs than that below the mark.

*Raiſing*

*Raiſing theſe Plants without Stoves and Fire-heat.*

We having occaſionally obſerved, that it was poſſible to raiſe and fruit this favourite plant without the aid of ſtoves or fire-heat, by the heat of hot-beds only, under proper frames: the hot-beds for this purpoſe are either of tanner's-bark, aſſiſted by occaſional dung linings, or may be compoſed of dung, having a foot of tan or ſaw-duſt at top, in which to plunge the pots, and aſſiſted alſo by proper linings of dung.

This method, however, though apparently conſiderably the leaſt expenſive, is attended with much more trouble and uncertainty than the ſtove culture already treated on, having the conſtant aid of bark hot-beds, and fire-heat in winter.

However, for the advantage of thoſe who cannot eaſily obtain a plenty of tanner's-bark, and who have no mind to go to the expence of erecting ſtoves, and burning fire ſix months in the year, and are diſpoſed to make trial of raiſing Pines by the above methods, we ſhall proceed to give ſome hints for the manner of effecting it, though we do not recommend it as a generally ſucceſsful practice.

I before noticed in the ſtove culture, that the crowns and ſuckers immediately from the mother-plant may be readily ſtruck, i. e. rooted, and ſet to growing in a tan or dung hot-bed, under a common cucumber or melon-frame; the dung-bed having ten or twelve inches depth of tan at top, or, in default thereof, ſaw-duſt, but tan is beſt, in which to plunge the pots containing the plants, and by ſhifting them into one or two new ſuch ſubſtantial hot-beds, with the addition of occaſional linings of the ſame material, the plants may be continued there all winter, or even until the following autumn, provided the frames were of due depth for the plants to grow.

But for this purpoſe it is proper to be provided with two different ſized wood-frames, furniſhed with ſuitable glaſs lights, particularly for this method of culture, one by way of a nurſery-frame, to ſtrike and rear the plants, and another of a greater depth, fo fruiting them, as adviſed for the ſtoves.

The firſt of theſe frames being intended as a nurſery-frame for rearing the crowns and ſuckers, its dimenſions may be ten or twelve feet long, ſix wide, three and a half deep at back, and two and half in front, with three ſliding lights at top, and if half the depth of the front was glazed it would be an advantage; which frame, at the proper time for planting the crowns and ſuckers, i. e. Auguſt and September, is placed upon a bark-bed, or ſubſtantial dung hot bed covered with tan, to plunge the pots in, or, for want of that, ſaw-duſt, but the former is greatly preferable; obſerving, if you uſe dung-beds, three or four different new ones, with occaſional linings, as hereafter deſcribed, will be required to ſupport the growth of the above young plants a year, or till fit for the fruiting-frame, being careful to ſupply them at due times with freſh air and water, as directed in the ſtove-culture, though, in this place, as having no fires to dry the damps, they muſt be very ſparingly watered in winter.

The fruiting frame being intended to fruit the plants, muſt be deeper than the former, and the whole front and ends, as well as the top, glazed, and may be made to place on the top of a raiſed pit of the ſame width and length, and three feet and half deep, formed either by a wall of brick or ſtrong inch planking, in which to make the hot-bed; which pit is more particularly eligible, if you intend to have a bark hot-bed: but as to the dimenſions of the frame itſelf, it may be twelve feet long, ſix in width, four and half deep in the back, and two and a half depth in front, having three ſliding ſaſhes in the front, and one at each end, and the whole covered at top with three glaſs lights to ſhove up and down; the glazing at top done imbricatum, as directed for the hot-houſe, ſee HOT-HOUSE; having alſo a painted canvas or old ſail-cloth on a roll, or ſome other covering, to uſe on nights, to defend the glaſſes. As to the pit, it may be ſunk eighteen inches, if dry ground, allowing width and length enough to build a nine-inch brick wall on every ſide, to form the cavity of the pit of due dimenſions to receive the frame at top of it, which wall is to be three feet ſix inches high from the bottom; or, if the back part was of inch deal, would be more convenient to admit the benefit of lining, to renew the heat; or, inſtead of brick, a pit formed entirely of poſt and planking; or a moveable wood one would anſwer the ſame purpoſe: upon this brick pit, or wood frame, the glaſs frame of the aforeſaid dimenſions is to be placed, and the hot-bed is to be made in the pit to its full depth. To render it ſtill more convenient, one ſuch frame might be made to ſerve two pits, making it to ſlide from one to the other, having a partition between; and when one bed has declined its heat,

make

make a fresh one in the spare pit, so slide the frame over it, and move the plants therein; the utility of this will be very obvious in practice, especially if the hot-bed is composed of dung, which will require renewing three or four times in the course of the year.

This is the general construction of the fruiting-frame.

In the pit of this frame a hot-bed of tan, or of dung covered with tan, &c. before hinted, is to be made the latter end of September, for the reception of the plants from the nursery frame, observing, if the bed is of dung, make it substantial enough for the top to be within eight or ten inches of the top of the pit when fully settled, upon this lay the tan or saw-dust above-mentioned, and in which plunge the plants in the same order as in the hot-house, giving fresh air and water, agreeable to the directions in the stove-culture, but being still careful to water with great moderation in these frames during winter, and cover the glasses every night.

If the hot-bed of this frame is of tanner's-bark, it, by the aid of dung linings at back of the pit, will support a due temperature till February, then stirring it up, as directed in the stoves, renews the heat till April, and then, by adding a little new tan, and another forking up, and occasional linings, it will support a sufficient heat to bring the fruit to maturity; but if the bed is of dung covered with tan, &c. two new beds, with occasional linings, will be requisite to carry the plants through the winter; that is, one bed when the plants are first placed in the frame in September, and another new one in the middle or end of December, and about two more to bring the fruit to perfection: hence the utility appears of having two pits, as you can then conveniently make a new bed in the spare-pit in due time, to acquire a proper temperature to be ready to receive the plants in their pots immediately from the declined hot-bed, at the same time shoving the frame from thence over the new one. Observe, in the mean time, during winter, that as soon as you perceive the heat of the bed, either that of tan or dung, begins to abate, you begin to line the back part of the pit and frame on the outside with hot dung, both to enliven the heat of the bed, and assist in warming the internal air of the frame: this lining should be laid three feet wide, at least, at bottom, and a little sloping at top, that the wet may pass off freely; neither should it be raised to the full height at first, but a little at a time, as the frost or severe weather increase, till at last it become as high as the whole back-part of the pit and frame together, continuing it also, as the cold advances, round the ends and front of the pit, at each time laying hay, fern, or other dry litter upon the lining, which preserves the heat the longer, and prevents the frost from penetrating the frame; and by thus gradually lining the beds, as the severity of the weather shall demand, it will maintain the due temperature of heat much longer, and more regular than if the whole quantity was to be added at once; observing, when the heat of these linings is much decreased, it must be renewed by the addition of some fresh dung, and the whole forked over to the bottom, which is to be repeated as you shall see occasion.

By observing the above directions in the management of the hot-bed, and giving fresh air at all due opportunities consistent with the rules laid down in the stove culture, and moderate waterings at times in fine sunny weather, the plants will shew fruit in February or March, which will ripen at the usual time in as good perfection as can be expected.

BROOMS, for the use of gardens.

In pleasure-grounds Brooms are almost daily wanted, especially in summer, and the best sorts for this use are those of Birch, made of the finest brush-wood, that will not soon become stubbed; nor should they be made very large and clumsey, which would tear up and deface the grass and gravel.

Heath Brooms are sometimes used, but these are not near so good as Birch ones for gardens.

In default of Birch, Beech-Brooms are also sometimes used, which being made flat, spreading, and light, they will answer tolerably for sweeping the mowings of short grass, and fallen leaves off grass-ground; but are not so fit for use on fine gravel, except lightly to whisk it from fallen leaves.

BRUNSFELSIA.

There is but one species, a shrubby exotic of the stove, garnished with simple leaves and funnel-shaped flowers.

Class and order, *Pentandria Monogynia*.

*Characters.*] CALIX is monophyllous, bell-shaped, five-parted, and permanent. COROLLA, a funnel-shaped petal, the tube long, but spreading and five-parted at top. STAMINA, five filaments inserted into the corolla,

and oblong antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and thick ſtigma. PERICARPIUM, a globular berry of one cell, having numerous ſeeds.

The ſpecies is,

BRUNSFELSIA *Americana.*

*American Brunsfelſia.*] Brunsfelſia with a woody, branching, rough ſtem ſix or eight feet high, garniſhed with oblong, entire leaves on foot-ſtalks, and large whitiſh flowers by threes or fours at the ends of the branches, ſucceeded by round, ſaffron-coloured, ſoft fruit.

This plant may be raiſed here from ſeeds in the ſpring, ſown in pots, and plunged in a bark-bed; and may alſo be propagated by cuttings in the ſame ſeaſon planted in pots, plunging them alſo in a bark-bed or other hot-bed under glaſſes; and the plants muſt always remain in the ſtove.

BRYONIA, the White Briony, or Wild White Vine.

The plants are herbaceous climbers, conſiſting of annuals and perennials; of the latter are about two ſpecies that merit notice by way of variety, one a hardy plant of Engliſh growth, the other an exotic that requires ſhelter in winter.

Claſs and order, *Monoecia Syngeneſia.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant, having a monophyllous bell-ſhaped cup, five-parted at top. COROLLA is bell-ſhaped, five-parted, and adheres to the calix. STAMINA, the male flowers have three ſhort filaments, two of which have double antheræ, the other one. PISTILLUM, in the female flowers a germen under the corolla, a trifid patent ſtyle, and ſpreading emarginated ſtigma. PERICARPIUM, a ſmooth oval berry, having oval ſeeds adhering to the ſkin.

[1]BRYONIA *Alba.*

*Common White Briony.*] Briony with a large, thick, fleſhy, white root, ſending up annually very long climbing ſtalks and branches, garniſhed with large, palmated, rough, callous leaves, and numerous cluſters of white flowers in May and June, ſucceeded by bright red berries.

[2]BRYONIA *Africana.*

*African Tuberous-rooted Briony.*] Briony with a large tuberous root, ſending up annually ſeveral ſlender rambling ſtalks, having palmated, five-parted, ſmooth leaves, their lobes cut and pinnatifid, and cluſters of greeniſh flowers, ſometimes ſucceeded by berries having ripe ſeed.

Both the ſpecies have perennial roots, but their ſtalks die annually in autumn.

The *Bryonia Alba* is a wild plant of England, inhabiting dry banks under hedges, where the roots acquire a monſtrous ſize, ſending up ſtrong climbing branches, running many feet long, and attach themſelves to the buſhes, or the firſt thing they encounter in their progreſs, and make a ſingular appearance, but it is ſeldom admitted in gardens, though a plant or two for variety merits a place in large grounds as climbers.

The root of this ſpecies is alſo in great requeſt for medical uſes.

Its propagation is eaſily effected by ſowing the berries in ſpring in a dry light ſoil where the plants are to remain, and when they come up, thin them to a conſiderable diſtance.

The African ſort muſt be kept in pots, to be moved under ſhelter of a frame or greenhouſe in winter.

It is raiſed by ſeeds in a hot-bed in ſpring.

BRYONA NIGRA. See TAMUS.

BUBON, Macedonian Parſley.

This genus compriſes herbaceous and ſhrubby plants; the former have little merit, but of the latter are two ſpecies proper to be admitted in the green-houſe collection.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbelliferous flowers, having a five-leafed involucrum; the general umbel compoſed of about ten ſmaller; each ſmaller one of fifteen or twenty rays, and a ſmall permanent calix to each floret. COROLLA, each floret of the umbel conſiſts of five ſpear-ſhaped inflexed petals. STAMINA, five filaments and ſimple antheræ. PISTILLUM, an oval germen below the corolla, two reflexed ſtyles, and blunt ſtigmas. PERICARPIUM, none; an oval two-parted fruit, having two ſeeds.

The ſpecies of note are,

[1]BUBON *Macedonicum.*

*Macedonian Herbaceous Bubon.*] Bubon with many compound leaves from the root, on longiſh foot-ſtalks, each leaf compoſed of many oval rhomb-ſhaped indented lobes, and in the midſt a branching flower-ſtalk about fifteen inches high, having all the branches terminated by white umbels in July, and ripe ſeed in autumn.

[2]BUBON *Galbanum.*

*Shrubby Galbanum-bearing Bubon.*] Bubon with an erect woody-ſtalk growing eight or ten feet high, having a purpliſh-coloured powdered bark, leaves at the joints, compoſed

poſed of many rhomb-ſhaped, indented, ſmooth folioles, and the ſtalks ſurmounted by yellow umbels in September, but no ſeeds in England.

[3]BUBON *Gummiferum.*

*Shrubby Gummiferous Bubon.*] Bubon with an erect woody ſtem, garniſhed below with leaves compoſed of many rhomboid, ſawed, ſmooth folioles, thoſe above pinnatifid, narrow, and tridented, and the ſtalks crowned by white umbels in September, but rarely any ſeeds here.

Theſe two ſhrubby kinds, on breaking any part of them, impart a gummy cream-coloured matter, of which is prepared the *Galbanum* of the ſhops.

The *Bubon Macedonicum* is cultivated in ſome gardens for variety. It is propagated by ſeeds in ſpring, ſown in a bed of common earth, and in autumn tranſplant the plants into a warm border, and ſome in pots for occaſional ſhelter. In about three years they will flower and perfect ſeeds, then totally periſh.

The two ſhrubby Bubons are natives of Africa, and require ſhelter of a green-houſe here in winter, ſo muſt always be cultivated in pots.

They are raiſed from ſeed procured from Africa, ſowing it as ſoon as poſſible in pots of light earth, to be occaſionally ſheltered from froſt, and in ſpring plunge them in a hot-bed, where the plants will riſe, and be fit to plant in ſeparate ſmall pots in May or June, plunging them alſo in a moderate hot-bed, and ſupply them with occaſional ſhade, water, and freſh air, to which fully expoſe them in July, and in October remove them to the green-houſe.

BUDDLEJA, *Buddleja.*

It compriſes two ſhrubby plants of the hot-houſe, decorated with ſimple leaves, and monopetalous flowers in ſpikes.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX is ſmall, divided into four parts, and permanent. COROLLA, a bell-ſhaped quadrifid petal. STAMINA, four ſhort filaments in the diviſions of the corolla, and ſhort antheræ. PISTILLUM, an oval germen, ſhort ſtyle, and blunt ſtigma. PERICARPIUM, an oblong capſule of two cells, and numerous ſeeds.

The ſpecies are,

[1]BUDDLEJA *Americana.*

*American Buddleja.*] Buddleja with a woody whitiſh ſtem and oppoſite branches, growing eight or ten feet high, garniſhed with oval, ſawed, oppoſite leaves, downy underneath, and yellow flowers in branching ſpikes from the ends of the branches.

[2]BUDDLEJA *Occidentalis.*

*Occidental Buddleja.*] Budleja with a woody ruſſety ſtem, growing fifteen or eighteen feet high, ſending out many ſlender branches, adorned with ſpear-ſhaped, pointed, entire leaves, placed oppoſite, and large, looſe, whorled ſpikes of white flowers at the end of every branch.

Theſe two plants are of American growth, and preſerved here in our ſtoves for variety.

They are propagated by ſeeds procured from America, which ſow in pots of light earth; plunge them in a hot-bed, and give light waterings thrice a week, and the plants are to be tranſplanted into ſeparate pots, and placed again in the hot-bed, or in that in the ſtove, where they muſt be always continued.

BULBOCODIUM, Mountain-Saffron.

Two ſpecies only belong to this genus, ſmall, bulbous-rooted, flowery perennials of the common ground, having funnel-ſhaped hexapetalous flowers three or four inches high, ſix ſtamina, and one ſtyle.

The ſpecies are,

[1]BULBOCODIUM *Serotinum.*

Late-flowering Mountain-Bulbocodium, with narrow ruſh-like leaves.

[2]BULBOCODIUM *Vernum.*

Spring-flowering Spaniſh Bulbocodium, with ſpear-ſhaped concave leaves.

They may be propagated by off-ſets at the decay of the flower and leaf every ſecond or third year; alſo by ſowing the ſeed in pots in autumn, ſheltering them in a frame from froſt, and the plants will appear in ſpring, which, at the decay of the leaves, may be taken up for planting in the borders in October, where they will flower the year following.

BULBUS, a Bulb, or Bulbous root, *Radix Bulboſa*; or, according to naturaliſts, a kind of great bud produced under-ground upon the crown of the root of certain herbaceous perennials, ſuch as the onion, lily, tulip, &c. hence denominated Bulbous-rooted plants.

In Bulbous plants, what we commonly call the root is defined to be only a ſort of large bud, compoſed moſtly of the rudiments of leaves, which encloſe and ſecure the embryo of the future ſhoot of the flower; for, at the lower part of this bulb may be obſerved a fleſhy knob or tubercle, from which

proceed a number of fibres attached thereto, is properly ſpeaking the true and genuine root from which the flower-ſtem immediately riſes, and that the upper part or bulb is, as before hinted, in moſt ſorts, partly the remains or rudiments of former leaves, as well as the rudiments of future ones, ſerving for a certain time as a cradle or nurſery, to defend from the injuries of weather the embryo plant, that is, the leaves and future flower-ſtem in miniature, which, after being repaired a certain number of times annually, the whole bulb and root periſhes, not, however, till it has produced from its ſides annually ſeveral ſmaller bulbs, off-ſets, or ſuckers, for perpetuating the ſpecies; for each ſucker becomes an individual, producing flowers and ſeed like the parent; forms alſo new ſuckers, which, in their turn, produce others, and in this manner multiply the ſpecies as certainly as the ſeed: for it is obſervable, that the remains of the former leaves ſunk below, and the rudiments of the future ones, forming ſeveral coats or rinds, whereof the bulb conſiſts, ſucceſſively periſh and ſhrink up into ſo many dry ſkins, betwixt which, and in their centre, are formed other leaves and rinds, and thus the bulb is perpetuated, till arrived at a certain ſtate of growth.

Bulbous-roots differ eſſentially from tuberous-roots, which conſiſt of an entire ſolid fleſhy ſubſtance, as turnep, potatoe, carrot, radiſh, &c. See TUBEROUS-ROOTS.

Of Bulbs there are two principal ſpecies or kinds, viz. Tunicated Bulbs——Squamous Bulbs.

Their deſcriptions are,

[1]BULBUS TUNICATUS, Tunicated, or Coated Bulbs, compoſed of ſeveral tunics, or coats, cloſely enfolding each other, as in the *Allium Cepa*, or onion, &c.

[2]BULBUS SQUAMOSUS, Squamous, or Scaly Bulbs, conſiſting of many ſcales, or thin plates, or ſmall oval parts placed over each other imbricatum, i. e. in the manner of ſcales of fiſh, or tiles on an houſe, as in the *Lilium*, or lily.

The above two ſpecies of bulbs comprehend ſome eſculents of the kitchen-garden, ſuch as garlick, onions, leeks, ſhallots, &c. and a numerous train of flowery plants, moſtly herbaceous perennials, producing beautiful garden-flowers, and moſt of them hardy enough to ſucceed in the beds and borders in the full ground.

The principal Bulbs of the flowery tribe are of the following genera:

Amaryllis, including the Guernſey lily, bella-donna lily, Jacobæa lily, &c.—Narciſſus, or daffodil, including jonquils—hyacinth—tulip—fritillaria, and crown-imperial—Lily, including martagons—ornithogalum, or ſtar of Bethlehem—galanthus, or ſnow-drop——leucojum, or great ſnow-drop—ſcilla, or ſea-onion—colchicum—albuca, or baſtard ſtar of Bethlehem—muſcaria, or muſk and grape hyacinth—iris, the bulbous and Perſian—hæmanthus, or blood-flower——Allium, or moly—crocus, including ſpring and autumn kinds—bulbocodium—pancratium, or ſea daffodil. For the different ſpecies and varieties of each ſort, ſee their reſpective genera.

Moſt ſorts of Bulbous roots multiply exceedingly by off-ſets, by which every particular ſort is continued, and new varieties are obtained from ſeed. See the culture of the reſpective ſorts.

Bulbous-plants for the moſt part may be ſaid to be perennial, for, although the ſame individual root exiſts but for a certain time, ſome not more than a year after having attained a flowering ſtalk, others longer, they, previous to their diſſolution, afford from their ſides a ſupply of ſuckers or off-ſets to perpetuate the reſpective kinds; ſo that, at the end of many years, what is ſtill often conſidered as the ſame individual root, is, in reality, another, as to every particle thereof.

All Bulbs renew their leaves and flower-ſtems annually, and their principal ſeaſon of flowering is at different times, from March to October, ſome producing their flowers at one time, and their leaves at another, as in ſome ſpecies of amaryllis and colchicum; others produce their flowers and leaves together, as the hyacinth, tulip, narciſſus, &c. and the leaves and flower-ſtem of all the ſorts periſh annually, at a certain period after flowering, at which time the root begins its period of reſt, drawing no nouriſhment from the ground, remaining in that inactive ſtate ſix weeks or two months; within this period of inactivity of theſe roots, before they put out new fibres to prepare for the future flower, is the only proper time to remove them, either to ſeparate the off-ſets for propagation, or to plant the roots in freſh prepared earth, or remove them to any other part of the garden, or to ſend to any diſtance; likewiſe to reſerve the Bulbs out of ground for autumn planting,

planting, when the beds or borders can be more conveniently prepared again for their reception; for moſt ſorts, taken up at the above-mentioned period of reſt, may be kept out of ground ſeveral months, even if occaſion requires; ſome ſorts from the time the flowers and leaves decay in May, June, or July, until the following ſpring, as often practiſed, when intended by ſpring planting to retard the time of flowering, to obtain a longer ſucceſſion of bloom, by ſucceeding that of the autumn plantations.

It is however particularly neceſſary to take up all the choice kinds of Bulbs annually, to ſeparate the off-ſets for encreaſe, as well as to freſh prepare the earth of the beds and borders, to promote the merit of the ſucceeding year's bloom; this is particularly proper for the curious tulips, hyacinths, narciſſus, &c. as to the more inferior ſorts of Bulbs in general, they ſhould alſo be removed every other year, or as often as their off-ſets are conſiderably encreaſed in number, which, if permitted to remain ſo long as to encreaſe into large bunches, they will cramp each other in growth, and produce but ſmall ill-nouriſhed flowers.

It is alſo proper to remark, that all Bulbs taken up at the above period of reſt in ſummer, I ſhould adviſe, where practicable, to plant the principal part again the following autumn, in October or November, as they will flower much ſtronger than thoſe kept out of ground till ſpring.

BULBUS CAULINUS, a Cauline, or Stem-Bulb, i. e. Bulbs growing on the ſtem or ſtalk, oppoſed to thoſe before deſcribed, which grow only under-ground upon the root.

Theſe Stem-bulbous plants have alſo a Bulbous root under ground, from which ſprings the ſtem that produce the Cauline Bulbs here alluded to, which plants are denominated bulbiferous, or bulb-bearing; of this kind are ſeveral ſpecies of *Allium*, ſuch as common garlick, rocambole, and ſeveral others of that genus, bearing ſeveral Bulbs, or ſmall cloves, on the ſummit of the ſtem, at the origin of their umbel of flowers, which, being planted, freely grow, become plants, and bear Bulbs as above; ſo that theſe kinds of bulbiferous plants are encreaſed both by the off-ſets from the root or main Bulb under-ground, as well as thoſe elevated upon the ſtem: the ſame obtains in ſome ſpecies of lily, ſuch as the *Lilium Bulbifera*, the bulb-bearing and fiery lily; alſo often in ornithogalum, or ſtar of Bethlehem, and ſome other liliaceous plants, which emit bulbs at the wings or angles of the leaves.

By the ſituation of theſe kinds of Cauline Bulbs, on different parts of the ſtem, furniſh eſſential marks for diſtinguiſhing certain ſpecies.

BUPHTHALMUM, including the *Aſteriſcus*, or Ox-Eye.

This genus furniſhes herbaceous and ſhrubby plants proper for the embelliſhment of the pleaſure-ground and green-houſe, all of which are garniſhed with ſimple leaves, and compound, radiated, and moſtly yellow flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, compound radiated flower, having an imbricated general cup, encloſing numerous florets. COROLLA, many hermaphrodite and female florets; the former compoſe the diſc, the latter the radius. STAMINA, in the hermaphrodite florets five filaments, having cylindric antheræ. PISTILLUM, in the hermaphrodite florets, an oval germen, ſingle ſtyle, and ſtigma; in the females a double-headed germen, ſimple ſtyle, and two ſtigmas. PERICARPIUM, none; a ſingle naked ſeed in each floret.

The ſpecies of moſt account are as follow: the firſt three are hardy herbaceous perennials of the full ground.

[1]BUPHTHALMUM *Helianthoides.*

*Helianthus-leaved American Ox-Eye.*] Buphthalmum with a perennial root, and annual ſtalks four or five feet high; oval-heart-formed, three-veined, ſawed leaves, placed oppoſite; and the branches terminated by large, radiated, yellow flowers, in leafy cups, appearing in July and Auguſt.

[2]BUPHTHALMUM *Salicifolium.*

*Willow-leafed Alpine Ox-Eye.*] Buphthalmum with a perennial root, and annual ſtalks about two feet high; ſpear-ſhaped, ſawed, hairy leaves, placed alternate; and the branches ending in radiated, bright, yellow flowers, in naked cups, appearing in June, July, and Auguſt.

[3]BUPHTHALMUM *Grandiflorum.*

*Smooth Willow-leafed Great-flowered Ox-Eye*] Buphthalmum with perennial roots; annual ſtalks two feet high; narrow, ſpear-ſhaped, ſmooth, ſlightly-indented leaves; and radiated yellow flowers, in naked cups, at the end of the branches.

The

The three following are of ſhrubby growth, and require ſhelter in winter.

[4]BUPHTHALMUM *Maritimum.*

*Maritime Sicilian Ox-Eye.*] Buphthalmum with a perennial root; very branching, perennial, firm ſtalks, about a foot high; wedge-ſhaped, hairy, alternate leaves; the branches crowned by radiated yellow flowers in blunt leafy cups, having foot-ſtalks, appearing moſt part of the year.

[5]BUPHTHALMUM *Fruteſcens.*

*Shrubby Ox-Eye of Jamaica.*] Buphthalmum with woody ſtalks and branches, riſing eight or ten feet high, adorned with ſpear-ſhaped, ſilvery, hoary leaves, of very different ſizes, placed oppoſite on foot-ſtalks, having two teeth near the baſe of each leaf, and pale yellow flowers in ſcaly cups from the ends of the branches, appearing from July until October.

*Variety.*] Shrubby Jamaica Ox-Eye with thick oblong leaves, having no teeth on the foot-ſtalk.

[6]BUPHTHALMUM *Arboreſcens.*

*Shrubby Bahama Ox-Eye.*] Buphthalmum with ſeveral ſhrubby ſtems directly from the root about a yard high, ligneous below, and ſucculent above, garniſhed with ſpear-ſhaped, thick, ſucculent, ſmooth, green leaves, placed oppoſite, and bright yellow flowers on longiſh foot-ſtalks at the ends of the branches, in July, Auguſt, and September.

*Variety.*] Shrubby Bahama Ox-Eye with hoary leaves.

All theſe ſix ſpecies are exotics, though the three firſt are hardy, the other three are tender; all of which flower here very ornamentally in ſummer and autumn, but rarely any but the three firſt ſorts afford ſeed in this country.

The firſt three ſpecies being hardy flowering perennials that proſper in any common ſoil, are proper furniture for the ornament of large gardens, in ſpacious borders, or in vacant ſpaces towards the fronts of the ſhrubbery compartments, where they will effect variety, and appear very ornamental ſeveral months in ſummer.

The fourth ſort, *Buphthalmum Maritimum*, or Sea Ox-Eye, requires ſhelter from froſt, ſo muſt be cultivated in pots, and in winter placed near a green-houſe or garden-frame, to have occaſional ſhelter in bad weather.

The fifth and ſixths ſorts and varieties require conſtant ſhelter of a green-houſe in winter, ſo muſt be always continued in pots, and placed to accompany the exotics of that department.

*Propagation of all the Sorts.*

The three firſt herbaceous kinds multiply freely by their roots, and by which they may be propagated abundantly in autumn or ſpring, either by taking off ſome ſlips from the roots, or to take them up, and divide them wholly into ſeveral parts, planting the ſlips in the places where it is deſigned they ſhall remain.

They may alſo be propagated plentifully by ſeeds, in a bed of common earth, in ſpring or autumn.

The Maritime ſort, and the other two ſhrubby kinds, are propagated eaſily by cutings of their branches, any time from April to July, planting them in pots of light earth, which, if plunged in a moderate hot-bed, will facilitate their rooting greatly, though thoſe planted in June and July will frequently emit roots tolerably well without that aſſiſtance, allowing occaſional ſhade and waterings.

After they are ſtruck, and advanced a little in growth, plant them in ſeparate pots, and let them remain in the full air till the end of October, then move them to the places of ſhelter before-mentioned.

BUPLEURUM, Hare's-Ear, and Shrubby Æthiopian Hartwort.

This genus retains both herbaceous and ſhrubby plants; the former poſſeſs little merit, but of the latter are two or three beautiful evergreen ſhrubs, one for the ſhrubbery, the others for the green-houſe.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbelliferous flower, having a many-leafed involucrum to the general umbel, and to the ſmaller umbels but five leaves; the main umbel compoſed of about ten ſmaller ones, and ſcarce any calix to the florets. COROLLA, each floret compoſed of five whole inflexed petals. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, a germen below the corolla, two reflexed ſtyles, and minute ſtigmas. PERICARPIUM none, a roundiſh compreſſed two-parted fruit, having two oblong ſeeds.

The ſpecies that merit culture are,

[1]BUPLEURUM *Fruticoſum.*

*Shrubby Æthiopian Hartwort.*] Bupleurum with a ſhrubby ſtem, dividing into numerous branches, forming a buſhy head five or ſix feet high, adorned with oblong-oval, entire leaves, of a pale green colour, placed alternate,

nate, and yellow flowers in umbels at the ends of the branches, in July and Auguſt, ſometimes ſucceeded by ripe ſeeds.

[2]BUPLEURUM *Differme.*

*Shrubby Differme-leaved Cape Hare's-Ear.*] Bupleurum with a ſhrubby branching ſtem, growing five or ſix feet high, garniſhed with two-formed leaves, the ſpring leaves being decompounded of many plane finely-cut lobes, ſucceeded in ſummer by others that are long, narrow, ruſh-like, angular, and trifid, growing in cluſters, and greeniſh flowers in ſpreading umbels at the ends of the branches in July, ſucceeded by ſeeds in autumn.

[3]BUPLEURUM *Villoſum.*

*Shrubby Hairy Æthiopian Hare's-Ear.*] Bupleurum with a ſhrubby branching ſtalk five or ſix feet high; oblong, indented, hairy leaves, downy below, their baſe half embrace the ſtalks; and ſmall umbels of flowers at the ends of the branches in July.

The firſt of theſe ſpecies have great merit as a hardy evergreen for the ſhrubbery, though it was formerly retained as a green houſe plant, being deemed too tender to proſper in the full ground; but experience has proved it to be of a tolerable hardy temperature, ſo as to ſucceed in the open air all the year in a dry ſoil; and being a handſome buſhy ſhrub, makes a fine appearance in the fronts of the ſhrubbery clumps.

The ſecond and third ſpecies being tender, muſt always be retained in pots, to have ſhelter of a green-houſe in winter; ſo muſt be allowed a place among the green-houſe exotics.

*Propagation.*

All the ſorts may be propagated both by ſeeds and by cuttings.

The ſeeds may be ſown in autumn ſoon after they are ripe in pots of light mould, placing them in a frame, to have ſhelter from froſt in winter, and in ſpring plunge them in a hot-bed, particularly the two green-houſe kinds, which will ſoon bring up the plants; theſe are to be innured to the full air, and tranſplanted into ſeparate ſmall pots, giving ſhade and occaſional waterings all ſummer; and in October placed in a green-houſe or frame; and in April following thoſe of the firſt ſort may be planted out in the nurſery.

By cuttings they may be raiſed in ſpring in pots of light earth, plunging them in a moderate hot-bed, where they will readily take root.

But the common Shrubby Æthiopian Hartwort may alſo be raiſed by cuttings in the common ground, planted in July, Auguſt, or September, and ſheltered occaſionally from froſt during winter; or they may be planted in pots at the above time, and placed in a garden-frame for occaſional ſhelter from froſt; and in either method the cuttings will emit roots in the ſpring, giving water freely all ſummer, and ſhelter again in winter; and in ſpring following plant them out in a ſheltered place in the nurſery.

BUTOMUS, Flowering Ruſh, or Water Gladiole.

There is but one ſpecies, an herbaceous, flowery, perennial aquatic, of tall growth, crowned by umbellate flowers.

Claſs and order, *Enneandria Hexagynia.*

*Characters.*] CALIX, umbellate flowers in a ſingle umbel, having a three-leaved involucrum. COROLLA, each floret of the umbel is compoſed of ſix roundiſh concave petals. STAMINA, nine awl-ſhaped filaments, and double lamellated antheræ. PISTILLUM, ſix oblong pointed germina, and ſingle ſtigmata. PERICARPIUM, ſix oblong pointed capſules, having ſingle cells filled with oblong ſeeds.

The ſpecies is,

BUTOMUS *Umbellatus.*

*Umbellated Butomus.*] Butomus with a thick, oblong, fibry root, crowned by many long flaggy leaves, and a thick, ſtrong, ſmooth flower-ſtalk, from three to five or ſix feet high, ornamented at top by a large umbellate cluſter of flowers, in June and July, ſucceeded by abundance of ſeed.

*Varieties of this are*] White-flowering Butomus—Red-flowered Butomus—Deep-purple-flowered Butomus.

Theſe plants are acquatics, and adorn our river-ſides, and other watery places, in moſt parts of Britain; but as they produce very ornamental flowers, all the varieties merit culture in gardens, accommodated with ſituations properly adapted for their growth, ſuch as in very moiſt places, by the ſides of any piece of water, rivulet, or any place of copious moiſture, where the roots may be moſtly in water, particularly any boggy or marſhy part, where theſe and ſeveral other of the aquatic tribe may be introduced, which will flouriſh, and render ſuch places very ornamental.

Their propagation may be effected by ſeed, or by the roots.

By ſeed, it may be ſowed thick in any watery or boggy place, as above, as ſoon as it is ripe, and left to nature. By roots, they may be removed any time after flowering, and

ſuch

ſuch that admit of it, may be divided, planting them at once in the places allotted them, where they will abide for years, and flower annually.

BUXUS, the Box-tree.

The plants of this genus are hardy evergreen ſhrubs, well calculated for ornamental purpoſes in ſhrubbery works, &c. of which there are but two ſpecies, one of them a large ſhrub, that admits of ſeveral beautiful varieties proper for evergreen plantations; the other is alſo a pretty evergreen of very dwarfiſh growth, but its chiefeſt merit is, for forming edgings to flower-beds and borders, for which purpoſe it is ſuperior to all other plants.

The wood of the large ſort is alſo of ſingular value for innumerable different ſorts of curious utenſils.

Claſs and order, *Monoecia Tetrandia*.

*Characters.*] CALIX, male and female flowers; the males have a three, and the females a four concave-leafed cup. COROLLA, in the males two, and the females three ſmall concave petals. STAMINA, the males have four filaments, and double antheræ. PISTILLUM, the females have a roundiſh trigonous germen, three ſhort ſtyles, and hiſpid ſtigmas. PERICARPIUM, a roundiſh trilocular capſule, each cell having two oblong ſeeds.

The ſpecies are,

[1]BUXUS *Arboreſcens*.

*The Tree-Box.*] Buxus with a tree-like ſtem, dividing into numerous branches, forming a regular head, growing twelve or fifteen feet high, and very cloſely adorned with ſmall ſtiff ſhining leaves.

*Varieties of this.*] Tree-Box with oval leaves, or Broad-leaved Tree-Box—Tree-Box with narrow leaves, or Narrow-leaved Tree-Box—Silver-ſtriped-leaved Tree-Box———Silver-edged-leaved Tree-Box—Gold-ſtriped Tree-Box—Gold-edged Tree-Box——Gold-tipped Tree-Box—Curled-leaved Striped Tree-Box.

[2]BUXUS *Suffruticoſa*.

*Dwarf Shrubby Box.*] Buxus with many ſmall, ſhort, very branchy ſtems, immediately from the root, riſing a foot and half high, cloſely adorned from the very bottom with ſmall, round, ſtiff leaves.

*Varieties.*] Dwarf Shruby Green Box—Dwarf Shrubby Striped Box.

The flowers of all theſe plants are very inconſiderable, ſo that the beauty of the ſhrubs conſiſts in their numerous, ſhining, evergreen leaves.

All the ſorts are ſo hardy, that they proſper in any expoſure and ſoil, and no weather injures them.

The firſt ſpecies, *Buxus Arboreſcens*, and its varieties, being of beautiful growth, are elegant furniture for the ſhrubbery plantations, for having numerous branches, very cloſely garniſhed with their ſmall ſhining leaves, effect a very ſtriking and agreeable contraſt at all ſeaſons, in aſſemblage with the larger-leaved evergreens.

This ſhrub is alſo ſometimes uſed in forming low evergreen hedges for ornament, and is likewiſe ſometimes planted as ſingle objects, trained into pyramids, globes, &c.

This ſort merits culture alſo for its wood, which, being very hard, is of ſingular uſe to the mathematical-inſtrument-makers, engravers, and turners, for making innumerable ſmall utenſils.

The wood is ſo compact and heavy, that it will ſink in water.

If therefore any one would cultivate this tree for its wood, may plant it on almoſt any dry poor ſoil, even on the declivities of chalky or gravelly barren hills, where they will grow freely, as is evident by the vaſt numbers that adorn Box-hill in Surry, about twenty miles from London, which bring a conſiderable income to the owner; and what is remarkable, the wood is ſold by weight, at ſo much per pound, which renders it ſtill more valuable to the cultivator.

The ſecond ſpecies, Dwarf Shrubby Box, is a valuable little plant, for its uſefulneſs in forming edgings to beds and borders, for which uſe there is no plant ſo proper, it fixes its roots ſo firmly in the ground, and its branches coming out ſo thick and cloſe to the very ſurface, that it anſwers effectually the purpoſe of a beautiful edging, and of ſecuring the earth of the beds or borders from being forced out, either by heavy rains, or doing the neceſſary work; ſo that, as an edging, it is both uſeful and ornamental.

It may alſo be trained as a dwarf ſhrub, permitting it to take its natural growth, when it will make proper furniture for the fronts of ſmall clumps.

This ſort is alſo by the gardeners about London trained in different figures, as globes, pyramids, and the like, for market, which, as it bears the ſmoke, is proper to plant in pots, to adorn court-yards and balconies.

*Propagation of all the Sorts.*

The Tree-Box and varieties may be raiſed abundantly by ſeeds, layers, and cuttings, though

though the two latter are the methods by which they are moſt commonly propagated, and indeed is the only method of propagation for the variegated ſorts, ſo as to continue the different kinds with certainty.

If it is however intended to raiſe the common green ſort by ſeed, ſow it in autumn ſoon after they ripen, in a border of light earth half an inch deep, and the plants will come up in ſpring, and in two years will be fit to plant out in the nurſery-lines.

To encreaſe them by layers, it may be done any time in the year; but from Michaelmas to March is the moſt eligible ſeaſon.

Cuttings of all theſe tree ſorts may be planted in autumn, or even any time in winter or ſpring, but the ſooner the better: chuſe ſhoots of one or two year's wood, about eight, ten, or twelve inches long; plant them in a ſhady border half way in the earth, and ſix inches diſtance, and give water in dry weather.

The Dwarf Box propagates very plentifully by numerous off-ſets or ſuckers from the roots, which may be parted any time from September to April, or even later, upon occaſion; obſerving, thoſe of them you intend to train as ſhrubs, are to be planted ſingly in rows in the nurſery a foot aſunder; but when intended for edgings, they are to be planted cloſe to one another, in the following manner.

*Of planting the Dwarf Sort for Edgings.*

As before noticed, the Dwarf Box is the beſt plant for edgings, and its propagation is effected abundantly by dividing the plants into as many parts as are furniſhed with fibres; alſo the ſlips of the branches, having no roots, will grow, but as the plants encreaſe greatly from the bottom, furniſhed with plenty of fibres, and are eaſily parted, it is moſt adviſeable for edgings, to uſe entirely thoſe ſlips that are provided with roots.

For the purpoſe of edgings, ſuch plants as are ſhort and buſhy are to be preferred, rejecting ſuch as have long, naked, ſticky ſtems and branches, and preference is to be given to thoſe whoſe roots are ſhort and very fibrous.

The plants are cultivated for ſale, purpoſely for edgings, in many places, particularly in the nurſeries and other gardens about London, which being planted in cloſe rows in the manner of edgings, is commonly ſold by meaſurement, generally from three-pence to ſix-pence per yard, running meaſure, and one yard of good cloſe Box will, when parted, plant three or four.

In ſlipping or parting the Box for edgings, it is not proper to divide it into very ſmall ſlips, and, if poſſible, let each ſlip be furniſhed with fibres; for although the naked or rootleſs ſlips will grow, they are improper to be planted with the rooted plants, becauſe many may fail, and occaſion gaps in the edging. The plants when ſlipped ſhould be trimmed at root and top, cutting off or ſhortening long ſticky roots, and only trim the ſtraggling tops even; but by no means cut them too cloſe to appear ſtumpy.

The manner of planting the edging is this.

To plant a cloſe regular Box-edging, the edge of the bed or border which is to be planted muſt be made up full and even by line, then a ſlight trench muſt be cut about ſix inches deep, in which to plant the Box almoſt to the top, obſerve the following directions.

In the firſt place, proceed to ſtake out the intended width of your border, walk, &c. and place for the edging; then, if not done before, dig the edge along full and regular, and directly tread the top evenly all the way, to ſettle the earth equally, that it may not ſink in hollows hereafter; then, having previouſly marked on the ſtakes the proper height and level for the edging, ſtretch a line, if for ſtraight work, along the edge, agreeable to the ſaid mark of level, and with a ſpade make up the ground even to the line, finiſhing it level and ſmooth about a ſpade's-breadth all the way along the top; this done, ſtrain the line tight, and proceed to cut out a ſlight neat trench for the reception of the edging: the trench muſt be cut on the walk-ſide of the line, about ſix inches deep, cutting the ſide next the line nearly perpendicular, and as even as poſſible, turning the earth thereof towards the walk or alley, and it is then ready for the plants.

The Box being trimmed, as before directed, proceed to planting, placing the plants cloſe againſt the upright ſide of the trench, and ſo cloſe together, as at once to form a cloſe and regular edging, with the tops all of an equal height even with the line. As you proceed in planting, draw with the hand a little earth up to the plants, juſt to fix them in due poſition till the line or row is finiſhed, then with the ſpade trim in the remainder of the

earth almoſt even with the tops of the edging, and preſs it evenly thereto with the foot, to fix the plants as they are to remain, and the work is finiſhed.

When the edging is thus planted, obſerve, if there are any irregular parts, projecting either on the ſides or top, to go over it lightly with the garden-ſhears, and trim off any ſuch irregularities.

If theſe edgings are planted late in the ſpring, or early in autumn, while the dry hot weather continues, it will be neceſſary to give occaſional waterings, but more particularly thoſe planted late in ſpring.

The planting of Box-edgings may ſeem a tedious work to thoſe of little practice; but an expert hand will plant many yards in a day. The jobbing-gardeners about London are extremely clever at this work, they having great practice; for thoſe kind of edgings ſtill prevail greatly in the numerous pleaſure or flower-gardens in the environs of that city. I have known ſome of theſe gardeners for a wager plant ſixty yards in an hour, previouſly, however, preparing the trench, and trimming the box ready for planting.

As to the general culture of theſe Box-edgings, it conſiſts principally in clipping or ſhearing them with garden-ſhears once a year at leaſt, to continue them in regular order, and within due bounds, in reſpect to height and breadth, for they ſhould not be ſuffered to grow above three or four inches high, nor more than about two broad, for if more than that, they aſſume a clumſey appearance; beſides, when permitted to grow high and thick, they afford harbour for ſlugs, ſnails, and other deſtructive vermin.

The time of year to clip or ſhear theſe edgings is June; this is to be underſtood of thoſe that are cut once a year; but to have them extremely neat, they ſhould be clipped twice in the ſummer, i. e. May, and the beginning or middle of Auguſt.

It is adviſeable to clip them in moiſt weather, as they then cut freer, and the beauty of the edging is better preſerved, than when ſhorne in a dry and hot time, which is apt to occaſion the leaves to turn brown, and have a ruſty unſightly appearance for a long time. The ſame alſo happens when cut early in ſpring while froſty nights prevail.

When any of theſe edgings are grown very broad and clumſey, they ſhould be taken up, ſlipped or parted, and replanted in a compact neat edging, as above directed. The ſame ſhould likewiſe be practiſed to ſuch edgings as have large gaps in different parts, and ſuch alſo that are irregular by having high and low places, and where the plants have become naked and ſtubby.

---

# C.

CACALIA, Foreign Colt's-foot.

This genus furniſhes ſome hardy, herbaceous, tall, flowery perennials of the common ground, and ſome of ſhrubby growth for the green-houſe, garniſhed with ſimple leaves, and compound flowers in umbels at the ends of the ſtalks and branches.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, compound flowers, having many florets included in an oblong, ſcaly, general cup. COROLLA, ſeveral tubulous funnel-ſhaped florets five-parted at top. STAMINA, five ſmall filaments, and cylindric antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and two oblong revolute ſtigmas. PERICARPIUM none, a naked ſeed in each floret, crowned with down.

The ſpecies that merit culture are as follow: the three firſt ſpecies are hardy herbaceous perennials.

1 CACALIA *Alpina.*

*Alpine Purple Cacalia.*] Cacalia with fleſhy ſpreading roots, ſending up many kidney-ſhaped, thickiſh, indented leaves, on ſingle foot-ſtalks, and amongſt them the flower-ſtalk a foot and half high, branching upward, and all the branches terminated by umbels of purpliſh flowers, three in each cup.

*Varieties.*] Alpine Purple Cacalia with hoary leaves——with hairy thick leaves——ſmooth green leaves.

2 CACALIA *Suaveolens.*

*Sweet-ſcented Canada Cacalia.*] Cacalia with ſtrong very-ſpreading roots; ſtrong, erect, annual ſtalks ſix or ſeven feet high, garniſhed with

with triangular, ſpear-ſhaped, indented leaves, placed alternate, and white flowers terminating all the ſtalks in umbels.

[3]CACALIA *Atriplexifolia.*

*Atriplex-leaved Virginia Cacalia.*] Cacalia with a thick root, having many tubers, ſending up ſtrong annual ſtalks four or five feet high, adorned with roundiſh, heart-ſhaped, ſinuated, alternate leaves, and yellowiſh flowers crown the ſtalks in umbels, having five florets in each cup.

The above three ſpecies flower annually in June, July, and Auguſt, ſucceeded by plenty of ſeeds in October, when their ſtalks die to the ground, and new ones riſe in ſpring.

The four following are ſhrubby ſucculent exotics of the green-houſe.

[4]CACALIA *Ficoides.*

*Shrubby Fleſhy-leaved African Cacalia.*] Cacalia with ſhrubby, ſtrong, ſucculent ſtems and branches, growing ſeven feet high; fleſhy, taper, lance-ſhaped, pointed, compreſſed, powdered leaves; and white flowers in ſmall umbels at the ends of the branches, in autumn, winter, or ſpring.

[5]CACALIA *Kleinia.*

KLEINIA, *India Cacalia, or Cabbage-tree.*] Cacalia with a ſhrubby, thick, ſucculent ſtalk and branches, compoſed of many ſwelling diviſions or joints; long, narrow, ſpear-ſhaped leaves, their foot-ſtalks leaving ſcars; and carnation-coloured flowers in large cluſters at the ends of the branches, from Auguſt to October.

[6]CACALIA *Anteuphorbium.*

*Anteuphorbium, or Shrubby Æthiopian Cacalia.*] Cacalia with many ſhrubby, ſlender, ſucculent ſtalks, branching irregularly; oval-oblong, flat, ſucculent, alternate leaves, having three lines at the baſe of the foot-ſtalk.

[7]CACALIA *Papillaria.*

*Shrubby Papillary Cacalia.*] Cacalia with a ſhrubby, large, ſucculent ſtalk, branching irregularly; and narrow ſucculent leaves, their foot-ſtalks remaining on the branches like thorns.

The three firſt ſpecies and varieties are very hardy herbaceous perennials of the flowery tribe, which although not of any ſtriking beauty, are proper furniture for large pleaſure-grounds, to encreaſe the variety in ſpacious borders, or in the clumps between deciduous ſhrubs, or the border of ſhady walks, &c.

Their propagation is by dividing their roots any time in autumn, winter, or ſpring.

They may alſo be raiſed abundantly by ſeeds, either ſown, or permitted to ſcatter which, by means of their downy pappus, are often wafted to a conſiderable diſtance, and where they fall come up freely.

The four ſhrubby ſucculent ſorts, requiring a green-houſe here all winter, muſt always remain in pots of light ſandy earth, giving moderate waterings in ſummer, but as little as poſſible in winter, as being of a very ſucculent nature.

Theſe plants being ſingular in their growth, merit a place in every curious collection.

Their propagation is eaſily effected by cuttings of their branches, any time from March to July. Let the cuttings be five or ſix inches long, permitting them to lie a fortnight to heal the cut part; then plant them in pots of light mould, which you may plunge in a moderate hot-bed; though thoſe planted in ſummer generally take root freely without ſuch aſſiſtance.

CACTUS, *Melo-Cactus*, Melon-Thiſtle; Includes alſo the *Cereus*, or Torch-Thiſtle, and the *Opuntia*, or Indian Fig.

This genus furniſhes a curious collection of ſucculent exotics, of ſingularly ſtrange and different growths, inhabitants of the hot parts of America, and retained here for curioſity in our ſtoves and green-houſes.

Claſs and order, *Icoſandria Monogynia.*

*Characters.*] CALIX, a monophyllous, tubular-concave, deciduous cup. COROLLA, many broad obtuſe petals, the exterior ones ſhort, the inner ones largeſt and connivent. STAMINA, numerous filaments inſerted in the calix, and erect antheræ. PISTILLUM, a germen below the receptacle, cylindric ſtyle, and headed multifid ſtigma. PERICARPIUM, an oblong baccaceous fruit of one cell, having numerous ſeeds.

As the *Melo-Cactus*, or Melon-Thiſtle, aſſume very different ſtructures and appearances from the *Cereus*, or Torch-Thiſtle, and the *Opuntia*, or Indian Fig, many ſtill conſider them as three different genera; but their characters being the ſame, Linnæus ranges them all in the genus *Cactus*, under which we ſhall alſo place them, though, for diſtinction ſake, in three different claſſes, i. e. the *Melo-Cactus*, or Melon-Thiſtle; the *Cactus-Cereus*, or Torch-Thiſtle; the *Cactus-Opuntia*, or Indian-Fig.

*Firſt Claſs, the Melo-Cactus, or Melon-Thiſtle.*

The ſpecies of *Cactus* called Melon-Thiſtle, are plants of very ſingular ſtructure, being ſhaped like a great melon, having neither

viſible ſtem, branches, nor leaves, but appear like a large roundiſh fleſhy maſs or lump, ſitting cloſe to the earth, growing a foot or more high, ſome deeply ribbed longitudinally, and all of them cloſely armed with robuſt thorns, and ſome are crowned with a large tuft of downy matter, intermixed with ſharp ſpines.

There are but two real ſpecies of this ſort, which are,

[1]CACTUS *Melo-Cactus.*

*Great Melon-Thiſtle.*] Cactus with a roundiſh body a foot or more high, having fourteen or fifteen longitudinal angles or ribs, each beſet with nine or ten very thorny tubercles, and at top a large downy prickly crown, from which iſſue the flowers and fruit.

*Varieties.*] Great Melon-Thiſtle with ſtraight angles——with angles ſpirally twiſted——with contorted angles——with broad recurved ſpines.

[2]CACTUS *Mammillaris.*

*Mammillary, or Smaller Melon-Thiſtle.*] Cactus with a roundiſh oblong body near a foot high, cloſely covered with ſmooth tubercles, each armed with brown thorns diſpoſed in a radius, and between the tubercles whitiſh flowers in Auguſt, ſucceeded by oblong crimſon fruit ripening in winter.

*Variety.*] Small Melon-Thiſtle with white ſpines.

All the ſorts are perennial both in root and top, and are of many years duration.

Theſe very ſingular plants are natives of America, growing in the crevices of rocks, having ſcarce any earth for their ſupport, where the firſt ſort grows near a yard high, and half a one or more in diameter.

In this country they are preſerved as plants of curioſity, and require the conſtant accommodation of our beſt ſtoves, and muſt be planted in pots of light ſandy earth, placing them upon the top of the flues or ſhelves in winter, and in the bark-bed in ſummer, giving but very moderate watering in the hotteſt weather, and none at all in winter, they being of themſelves very ſucculent and replete with moiſture.

*Their Propagation.*

The propagation of theſe plants in England is by ſeed, in pots of light ſandy earth, plunged in the bark-bed, where they will ſoon come up, which, after having advanced a little in growth, ſhould be pricked in ſeparate very ſmall pots, plunging them alſo in the bark-bed, and they will make great progreſs, though it will be ſome years before they acquire any conſiderable ſize.

Young plants ſometimes iſſue from the ſides of the old ones; theſe may be taken off and planted, managing them as above.

But ſome, to have large plants as ſoon as poſſible, procure them from the Weſt-Indies in tubs of dry rubbiſhy compoſt, being careful during the voyage to guard them from cold and every ſort of moiſture, and as ſoon as they arrive, plant them in pots, and plunge them in the bark-bed till rooted.

*Second Claſs.*

CACTUS CEREUS, the *Cereus*, or Torch-Thiſtle, and Creeping Cereus.

This claſs conſiſts alſo of ſucculent perennial exotics of America, of ſingular ſtructure and port, and retained here for variety in our ſtoves.

Claſs, order, and characters, the ſame as the *Cactus Melo Cactus.*

The Cactus of this claſs are vaſtly different in ſtructure and general habit from thoſe of the preceding; thoſe of this claſs advance with long, angulated, naked, ſucculent ſtalks; ſome erected ſingly like a column to thirty or forty feet in height, having neither branches nor leaves; others are of creeping growth, with long, climbing, rooting ſtalks, branching and mounting themſelves upon ſupport to a great diſtance, and ſome trail upon the ground; all of which are for moſt part leafleſs, but moſt of them produce moſt elegant multipetalous flowers, which, in ſome of the climbing kinds, are of wonderful ſize and beauty, ſpreading like an umbrella a foot or more in diameter; and what is more remarkable, they appear only on nights, and which being ſo extremely fugaceous, that, opening fully about ten or eleven o'clock, they continue expanded three or four hours, then begin to ſhut and fade, and by ſix or ſeven in the morning are quite cloſed, hang drooping, and in a manner withered and decayed, never opening any more, though they are often ſucceeded by freſh ones on the ſame plant the following night; and thoſe of all the ſorts, in their native ſoil, are ſucceeded by a large, roundiſh, eatable fruit, but rarely ripen in perfection here.

They are preſerved here in many of our hot-houſes as curioſities, and, as ſuch, highly demand the attention of the curious.

The

The ſpecies of this claſs are,

[1]CACTUS-CEREUS *Hexagonus.*

*Great Upright Sexangular Torch-Thiſtle.*] Cactus with an upright, ſexangular, ſtrong, fleſhy, branchleſs ſtalk or column, growing thirty or forty feet high, armed with ſpines in radiated cluſters; and from the angles large white flowers in prickly cups on thick fleſhy foot-ſtalks, appearing in July, but rarely any fruit in England.

[2]CACTUS-CEREUS *Tetragonus.*

*Upright Smaller Quadrangular Torch-Thiſtle.*] Cactus with an upright, four-angled, fleſhy ſtalk, five or ſix feet high, ſending out many erect ſide-ſhoots, the angles compreſſed and armed with cluſters of ſpines.

[3]CACTUS CEREUS *Pentagonus.*

*Upright Pentangular Torch-Thiſtle.*] Cactus with an upright, five-angled, jointed column, twelve or fifteen feet high, having the joints far aſunder, and the angles armed with ſpines.

[4]CACTUS-CEREUS *Heptagonus.*

*Upright Septangular Torch Thiſtle.*] Cactus with an upright, oblong, ſeven-angled, fleſhy ſtalk, having the angles armed with ſpines.

[5]CACTUS-CEREUS *Repandus.*

*Upright Repand-octangular Torch-Thiſtle.*] Cactus with an upright, ſomewhat ſlender, eight or nine-angled ſtalk, the angles compreſſed and undated, armed with cluſters of ſpines at a diſtance, and greeniſh flowers in June, ſucceeded by large yellowiſh pear ſhaped fruit, ſometimes ripening in England.

[6]CACTUS-CEREUS *Peruviana.*

*Upright Peruvian Octangular Torch-Thiſtle.*] Cactus with an upright, eight or nine angled, fleſhy ſtalk, twenty or thirty feet high, the angles ſlight, obtuſe, and ſpinous, flowering in July, ſucceeded by a reddiſh, ſmooth palatable fruit.

[7]CACTUS-CEREUS *Lanaginoſus.*

*Upright Novem-angular Downy Torch-Thiſtle.*] Cactus with an upright, ſlightly nine-angled, thick, fleſhy, downy ſtalk, many feet high, armed with ſpines ſhorter than the down.

[8]CACTUS CEREUS *Royeni.*

*Royen's Upright Decem-angular Torch-Thiſtle.*] Cactus with an upright, articulated, ten-angled, fleſhy ſtalk, the articuli or joints oval, and the ſpines and down of equal length.

The following are the creeping Torch-Thiſtle.

[9]CACTUS-CEREUS *Grandiflorus.*

*Climbing Pentangular Grand-flowered Torch-Thiſtle.*] Cactus with climbing, five-angled, jointed, ſlender, branchy ſtalks, rooting at the joints, and extend conſiderably, producing grand, ſnowy white flowers, having large bright-yellow cups, expanding almoſt a foot diameter, of ſplendid beauty and moſt fragrant odour, opening in an evening, and by next morning are cloſed, hang drooping, and decay.

[10]CACTUS-CEREUS *Triangularis.*

*Climbing Triangular Torch-Thiſtle.*] Cactus with climbing, three-angled, jointed, ſlender, branchy, prickly ſtalks, rooting at the joints, and extend to a great diſtance, producing large, beautiful, nocturnal flowers, decaying next morning.

[11]CACTUS-CEREUS *Flagelliformis.*

*Trailing Decem-angular Flagelliform Torch-Thiſtle.*] Cactus with trailing, finely ten-angled or fluted, long, ſlender, prickly ſtalks, not jointed, rooting, nor climbing, but, if not ſupported, extend along the ground, producing many elegant bright-purple flowers annually in May of two or three days duration.

In all the ſorts, the flowers are compoſed of many broad petals, and each flowers ſtand on a ſhort foot-ſtalk.

All theſe ſpecies of *Cactus Cereus*, or Torch-Thiſtle, are ſucculent perennial exotics of the ſtove, perennial both in root and top, continuing their growth many years, always aſſuming a green colour.

They are all natives of the warm parts of America, and in this country require a ſtove; muſt therefore be always kept in pots of light, dry, ſandy earth, and continued conſtantly in that department; for, although they will live in the open air in hot weather in ſummer, they are too apt to imbibe moiſture, and being themſelves very humid, may occaſion them to rot, nor will they ſo certainly flower as when retained in the ſtove.

Be ſure always to pot them in light dry earth, and give them but very moderate waterings in ſummer, and very little, or none at all, in winter.

The upright kinds arrive to a great height in America; and in this country, in our ſtoves, they often obtain ten or fifteen feet ſtature, and were there room, they would apparently grow ſeveral feet higher; but when they reach the top, we are obliged to ſhorten them, in which caſe they iſſue forth ſide-ſhoots, proceeding in an upright direction like the main ſtem, and, if taken off and planted, they readily emit roots, and become proper plants.

The

The creeping kinds will alſo extend themſelves conſiderably, provided they have ſupport, ſo ſhould be placed near the walls of the ſtove, and their branches trained thereto, which, of the *Grandiflorus* and *Triangularis* kinds, will root in the plaiſter-work as they aſcend.

Moſt of the ſpecies, both the upright and creeping kinds, produce flowers in this country, though not all of them annually, and ſome not in two, three, or more years; for they have no certain period of flowering here, and the flowers are very rarely ſucceeded by fruit.

No flowers however are, at any rate, to be expected till the plants have obtained ſeveral years growth, to acquire due ſtrength.

The firſt and twelfth of theſe ſpecies are the hardieſt of all, and may be preſerved in a good green-houſe, giving no water in winter, and will endure the open air from June till September, but rarely flower well unleſs indulged with a ſtove.

*Propagation of all the Sorts.*

They are all propagated by cuttings of their ſtems and branches, in pots plunged in a bark-bed or other hot-bed, in May, June, or July.

When intended to propagate any of the upright ſorts, ſuppoſing the plant to have only one ſtem and no ſide-ſhoots, there is no other method of encreaſing it than by cutting off the top to what length you pleaſe, which cutting, after lying in a dry place about a fortnight to heal the ſucculent wound, is to be planted in a pot of light compoſt, and plunged in the bark-bed, &c. and it will readily ſtrike root and grow. The remaining part of the old plant, from which the above cutting was taken, will ſoon put forth lateral ſhoots, which, when from three to ſix or eight inches long, may be taken off, and planted ſingly in pots, as above directed, and the old plant continues to furniſh a ſupply of freſh ſhoots annually.

The creeping kinds having ſeveral ſtalks and branches, may be propagated plentifully, taking off cuttings of them from about three to five or ſix inches long, treating them as above.

Cuttings of all theſe plants will keep two or three months out of the earth, in a dry place, if neceſſary.

*Third Claſs.*

[12]CACTUS-OPUNTIA, the *Opuntia*, or Indian Fig, or Prickly Pear.

This claſs of Cactus conſiſts alſo of curious ſucculent exotics, moſtly of American growth, and require the aid of green-houſes and ſtoves in this country.

Claſs, order, and character, the ſame as the CACTUS *Melo-Cactus*.

The plants of this claſs are compoſed of a multitude of thick, fleſhy, compreſſed, prickly leafleſs branches, growing out of one another in many oval and oblong articuli or joints, ſome compreſſed or flat, others ventricoſe or bellied; ſome looſely diſpoſed and ſpread near the ground, and ſome grow erect; all the ſorts producing multipetalous concave flowers from the ſurface and upper edge of all the articulations, ſucceeded by large, oblong, ſucculent, fig-ſhaped, prickly fruit, which in ſome of the ſorts ſometimes ripen in our gardens.

The plants in general are perennial in root, ſtem, and branches, have ſcarcely ever any leaves, but their ſucculent branches always aſſume a green colour.

The ſpecies of this claſs are,

[1]CACTUS-OPUNTIA *Opuntia*.

*Common Opuntia, or Indian Fig.*] Cactus with low, ſpreading, looſe branches, compoſed of many oval compreſſed joints, having knots on the ſurface, armed with ſlender briſtly ſpines, and yellow flowers at the upper parts of the articuli, ſucceeded by oblong, prickly, purple fruit, ſometimes ripening in England.

[2]CACTUS-OPUNTIA *Ficus Indica*.

*Greater Common Indian Fig.*] Cactus with many ſomewhat erect branches, compoſed of many oblong, oval, compreſſed joints, armed with long briſtly ſpines in radiated cluſters, and yellow flowers from the edges of the articuli, ſucceeded by large, purple, prickly fruit.

[3]CACTUS-OPUNTIA *Tuna*.

*Tuna Major, or Great Indian Fig.*] Cactus with erect ſtrong branches ſeveral feet high, compoſed of many large oval articulations, armed with numerous cluſters of long awl-ſhaped ſpines, and yellowiſh flowers.

[4]CACTUS-OPUNTIA *Cochinillifer*.

*The Cochineal Great Indian Fig.*] Cactus with erect, ſtrong, very green, articulate branches, riſing eight or ten feet high, compoſed of many oval, oblong, compreſſed, ſmooth articuli, almoſt without ſpines, and ſmall purpliſh flowers from the ſurface, ſucceeded by a large ſucculent fruit, having a blood-red pulp, on which feeds the cochineal inſect, ſo valuable in dying ſcarlet colour.

Upon

Upon this ſpecies, which is a native of Mexico and the Weſt-India iſlands, is found the inſect or bug called cochineal, which is uſed by the dyers as their principal baſis for ſcarlet colour. It is a ſix-legged viviparous inſect, produced from an egg in its perfect form, not undergoing any transformation: it has no wings, nor, indeed, has it uſe for any, the greateſt part of its life being ſpent on the vegetable whereon it feeds.

[5]CACTUS-OPUNTIA *Curaſſavicus.*

*Low Ventricoſe Opuntia of Curaſſoa, or Pin-pillow.*] Cactus with low, ſpreading, jointed branches, compoſed of many cylindric, very ſwelling, ventricoſe or bellied articulations, cloſely ſet with white ſpines; by the Americans is called Pin-pillow.

[6]CACTUS-OPUNTIA *Spinoſiſſima.*

*Moſt Spinous Opuntia, or Robinſon Cruſoe's Coat.*] Cactus with jointed branches, compoſed of very long, narrow, compreſſed joints, very cloſely armed with cluſters of long, ſlender, browniſh ſpines, croſſing each other every way; hence ſometimes called Robinſon Cruſoe's Coat.

[7]CACTUS-OPUNTIA *Periſkia.*

*Periſka, or American Gooſeberry.*] Cactus with a woody, taper, prickly ſtem; ſlender, ſpreading, ſucculent branches, armed with long whitiſh ſpines; lancelate-oval, thick, ſucculent leaves, whitiſh flowers, and a gooſeberry-ſhaped fruit.

[8]CACTUS-OPUNTIA *Phyllanthus.*

*Sword-blade Notched Opuntia.*] Cactus with many long, articulate, ſmooth, ſpineleſs branches, compoſed of long, ſword-ſhaped, very flat, thin joints, having repand indented edges, and from the indentures many pale yellow flowers.

Theſe are all the principal ſpecies of the Cactus-Opuntia cultivated in the Britiſh gardens.

The firſt of theſe ſpecies, *Common Opuntia*, is the hardeſt of all the ſorts, as it may be preſerved in England by the ſhelter of a green-houſe or garden-frame in winter, and it will ſometimes live all the year in the full ground under a warm wall; it is however proper to keep ſome in pots, to have ſhelter from froſt.

All the other ſorts require a ſtove moſt part of the year; for, although they will live in the full air two or three months in ſummer, and in a good green-houſe in winter, they, for want of a due temperature of warmth, are apt to aſſume a yellowiſh hue, and gradually dwindle off; but when kept moſtly in the ſtove, they always retain their reſpective natural green colour, and are more prolific in their flower and fruit: they, however, at any rate, muſt never be fully expoſed, but only two or three months in the heat of ſummer, and but very little in wet ſeaſons.

All the ſorts ſhould always be continued in pots of light ſandy ſoil, or dry rubbiſhy compoſt, giving frequent light waterings in ſummer, and alſo now and then lightly in winter, eſpecially thoſe in the ſtove.

*Their Propagation.*

They are propagated very eaſily by cuttings or joints of their branches, which may be taken off and planted in pots of light ſandy compoſt any time from the beginning of May to the end of July, but the ſooner the better.

The cuttings are to be cut off in joints, which, previous to planting, muſt, like other ſucculents, be laid in a dry place ten or fifteen days, to heal over the cut part; then plant them in pots as above, and if the hot-houſe kinds are then plunged in the bark-bed, or other hot-bed, it will greatly promote their rooting; but the green-houſe ſort, Common Opuntia, will readily ſtrike root without that aid, though they may be greatly forwarded by ſuch aſſiſtance, giving all the ſorts now and then moderate waterings, juſt to moiſten the earth a little.

CALENDULA, the Marigold.

This genus of plants conſiſts of herbaceous buſhy annuals, one low perennial, and one ſhrubby plant: the former compriſes hardy culinary herbs and flowery plants, and the two latter ornamental plants for the green-houſe, all of which have ſimple leaves, and compound radiated flowers.

Claſs and order, *Syngeneſia Polygamia Neceſſaria.*

*Characters.*] CALIX, a compound radiated flower, having a ſimple multipart general cup. COROLLA is compound, and conſiſts of numerous tubular hermaphrodite florets in the diſk, and many long flat females compoſe the rays. STAMINA, the hermaphrodites five ſhort filaments and cylindric antheræ. PISTILLUM, the hermaphrodites an oblong germen, ſlender ſtyle, and blunt bifid ſtigma; the females a trigonous germen, ſlender ſtyle, and reflexed ſtigma. PERICARPIUM none. SEMEN, a ſingle, oblong, incurved ſeed, in the female florets.

The ſpecies of note are as follow: the three firſt

firſt ſpecies and varieties are hardy annuals of the full ground.

[1]CALENDULA *Officinalis.*

*Officinal, or Common Garden Marigold*] Calendula with a ſhort ſtalk, dividing low into many buſhy branches a foot or two high, cloſely garniſhed with oblong oval leaves, and numerous radiated golden flowers at the ends of the branches, ſucceeded by boat-ſhaped, incurved, rough ſeeds.

*Varieties of this are*] Common Marigold with ſingle yellow flowers——with double yellow flowers,——Giant Common Marigold with very double flowers—with ſingle lemon-coloured flowers——double lemon-coloured flowers—with ſingle and double gold coloured flowers——with party-coloured flowers——with reflexed flowers——with proliferous or childing flowers, having many ſmall flowers iſſuing from the calix of the main one all around; of which there are, the Small Proliferous Marigold—Great Proliferous Marigold.

All theſe varieties are hardy annuals, riſing from ſeed in the full ground in ſpring, commonly flower in May or June, continuing a plentiful ſucceſſion until November, ſucceeded by abundance of ſeed, which, if gathered with care from the beſt of each reſpective ſort, may all be continued in diſtinct perfection; this ſhould be particularly obſerved in the Giant and other fine double and Poliferous kinds.

[2]CALENDULA *Pluvialis.*

*Cape Leafy-ſtalked Violet and White Calendula.*] Calendula with ſlender, very leafy, declining ſtalks, ſix or eight inches long; ſpear-ſhaped, ſinuated-indented leaves; and flowers from the ends of the branches, having the rays violet-coloured without, and white within, and purple bottoms.

[3]CALENDULA *Nudicaulis.*

Naked-ſtalked Violet and White Æthiopian Low Calendula.

The two following are green-houſe perennials.

[4]CALENDULA *Graminifolia.*

*Graſs-leafed Low Perennial Cape Calendula*] Calendula with ſeveral tufted heads near the root, covered with long, narrow, graſſy leaves, and amongſt them naked ſtalks eight or nine inches long, each crowned by one large radiated flower, having the rays purple without, white within, and purple bottoms, appearing from April till autumn.

[5]CALENDULA *Fruticoſa.*

*Shrubby Cape Calendula.*] Calendula with ſhrubby ſlender ſtalks and branches, growing ſix or ſeven feet high, garniſhed with oval leaves, and the branches terminated by radiated flowers, having the radius purple without, white within, and purple middles, appearing ſeveral months in ſummer.

The flowers of all the ſorts being compound and radiated, they, in their ſingle ſtate diſplay a naked diſc, or middle, compoſed of numerous, very ſmall, tubular florets; one or two ſeries of flat ſpreading ones form the radius, ray, or border; but in the full double flowers, the plenitude conſiſts of numerous flat florets, continued in many ſeries from the circumference to the very centre, forming a large full flower.

The firſt ſort, *Calendula Officinalis*, in its common ſingle-flowered ſtate, is regarded only as a pot-herb, and its flowers are the only parts uſed; but ſome of the full double varieties and proliferous kinds demand attention alſo as ornamental plants for the beauty of their flowers, which will effect an agreeable diverſity in the common compartments of the pleaſure ground, in aſſemblage with other hardy annuals.

Likewiſe the ſecond and third ſorts, being hardy annuals, will flower abundantly, and form a good variety in the open borders in June, July, and Auguſt.

The fourth and fifth ſorts, Graſs-leaved and Shrubby Calendula, producing many flowers in long ſucceſſion, are alſo worthy of a place in our gardens; but being impatient of froſt, muſt be kept in pots, to have ſhelter of a green-houſe or frame in winter.

*Propagation of all the Sorts.*

All the annual ſorts are propagated by ſowing the ſeeds in beds or borders in March or April, either in the places where they are to remain, or for tranſplanting.

When intended to cultivate the firſt ſort for culinary uſes, may either ſow the ſeeds where the plants are to remain, by broadcaſt on the ſurface, and rake them in, or ſow them in ſmall ſhallow drills a foot aſunder, covering them half an inch deep, and when the plants in either method have leaves an inch broad, hoe them out to twelve inches diſtance; or they may be ſown thick for tranſplantation, and when the plants have four or five leaves, plant them out in rows the above diſtance.

Their flowers being the uſeful parts, they will be fit for uſe in conſtant ſucceſſion from time

time to time in dry weather, and, after drying them in the ſhade, ſhould be put up in paper bags for uſe.

To propagate the annual kinds in general as flowering plants, ſow them either in patches in the borders, &c. where they are to remain, ſowing four or five ſeeds in each patch half an inch deep, but leave only one of the beſt of the plants in a place; or the plants may be raiſed in a bed or border, and when they have four or five leaves, tranſplant them in the order juſt directed.

They will flower and ripen ſeeds abundantly from June to the end of October.

The fourth ſort is propagated by ſlipping the heads any time from March till September, planting them in pots, which, if plunged in a hot-bed, or in the common earth, and cloſe covered with a hand-glaſs, and occaſionally ſhaded and watered, they will readily grow, hardening them gradually to the air.

The ſhrubby ſort is propagated by cuttings of its branches, in pots of light earth, in April, May, or June, plunging them in a moderate hot bed, or, in default thereof, plunge them to the rims in the common ground, giving ſhade and water.

CALIX, the empalement or flower-cup, which is the green outer part of a flower, that immediately incloſes and ſupports the bottom of the corolla or petals. See COROLLA.

According to modern botaniſts there are ſeven ſpecies of Calix, viz.

[1]*Perianthium*, which is conſiderably the moſt common ſpecies, and is that ſort of Calix which cloſely ſurrounds the flower. When we ſpeak therefore of the proportion, figure, or ſingularity of the Calix, we would be underſtood to mean that ſpecies of Calix called Perianthium. See PERIANTHIUM. The other ſpecies, which differ remarkably both in appearance and ſtructure from this, are always denominated by their own proper names to avoid confuſion, and which are termed

[2]*Involucrum* is a Calix at a diſtance from the flower, and belong principally to the umbelliferous plants. See INVOLUCRUM.

[3]*Amentum*, or Katkin, is compoſed of a multitude of ſcales, faſtened to an axis or thread. See AMENTUM.

[4]*Spatha*, a ſheath, which burſts lengthways, and protrudes one or more flowers, as in the Narciſſus, &c. See SPATHA.

[5]*Gluma*, the huſky Calix of the graſſes. See GLUMA.

[6]*Calyptra*, the Calix of the moſſes, is membraneous, very thin, and ſhaped like an extinguiſher, and is placed over the antheræ. See CALYPTRA.

[7]*Volva*, the Calix of the *fungi*, or muſhroom tribe is membraneous, and torn on the ſides. See VOLVA.

The uſe of the Calix is to incloſe, ſecure, and ſupport the other parts of the flower; to be their ſecurity before its opening, by intercepting all extremities of weather, and afterwards to be their ſupport, by containing all the parts in their due and moſt graceful poſture. Hence we have the reaſon why the Calix is frequently various, and ſometimes wanting. Some flowers have none, as tulips, and many other liliaceous plants; becauſe having a fat, firm leaf or petal, and each leaf likewiſe ſtanding on a broad and firm baſis, they are thus ſufficient in themſelves. Carnations, on the contrary, have not only a Calix, but that for greater ſupport, it is long, and of one piece; for otherwiſe, the foot of the petals being very long and ſlender, moſt of them would break out of compaſs; in the ſame flower the top of the Calix is indented into five parts, that the indentments, by lapping over the petals before their expanſion, protects them; and afterwards the ſame parts, by ſpreading regularly under the Corolla when expanded, affords it ſupport. The Calix or cup in moſt plants is ſingle; in ſome genera of the mallow tribe, as *alcea*, the holyhock, and *Altheæ*, marſh-mallow, it is double, or of two ſeries.

With reſpect to the number of leaves or pieces of which the Calix is compoſed, is either of one leaf, *monophyllum*; or of two, *diphyllum*; of three, *triphyllum*; or four, *tetraphyllum*; of five *pentaphyllum*, &c. or many leaves, *polyphyllum*; and when one is leaf divided into two, three, four, five, or more parts, it is termed *monophyllum-bifidum*, *trifidum*, *tetrafidum*, *quinquefidum*, &c. which leaves and diviſions are either equal, as in moſt plants; or unequal, as in rock-roſe, &c. in which, two of the five leaves of which the Calix conſiſts, are alternately leſs than the other three.

With reſpect to proportion, the Calix is generally ſhorter than the corolla in moſt plants, though in ſome genera it is equal, and in ſome longer.

With reſpect to compoſition, the Calix ſometimes conſiſts of a number of leaves laid over each other like tiles or ſcales, *imbricatum*, as in hawk-weed, &c. ſometimes of ſcales that ſpread wide and are diffuſed, or diverge on all ſides *ſquarroſum*, as in the thiſtle.

As to duration, the Calix either falls off at the firſt opening of the flower, *Calix caducum*, as in the poppy. With the flower, *Calix deciduum*, as in the barberry and the croſs-ſhaped flowers; or continues till the maturity of the fruit. *Calix perſiſtens*, as in the lip and maſqued flowers, and ſeveral others.

Laſtly, a Calix is proper to one flower, as in moſt plants with ſimple flowers; or common to many, as in ſcabious and the compound flowers.

CALLA, *Æthiopian Arum*.

Of this genus is one beautiful, herbaceous, flowery perennial of the green-houſe, adorned with large radical leaves, and a two-foot ſtalk, crowned by ſpadiceous yellowiſh flowers.

Claſs and order, *Gynandria Polyandria*.

*Characters.*] CALIX, a monophyllous, oval, heart-ſhaped, coloured, permanent ſpatha, protruding a digitated, ſingle, erect club or ſpadix, covered with the fructifications. COROLLA, no petals. STAMINA, many very ſhort filaments, and ſmall yellow antheræ. PISTILLUM, a roundiſh germen, ſimple ſtyle, and acute ſtigma. PERICARPIUM, each germen becomes a globular, pulpy, unilocular berry, containing a few obtuſe ſeeds.

The ſpecies is,

CALLA *Æthiopica*.

*Æthiopian Arum, or Sweet Calla.*] Calla with a tuberous, thick, fleſhy, brown root, crowned by cluſters of large heart-ſhaped, arrow-pointed leaves, on very long foot-ſtalks; and amongſt them upright flower-ſtalks two feet high, terminated by a ſingle ſpatha, protruding a yellowiſh ſpadix, covered with whitiſh fructifications of a muſky fragrance, ſucceeded by roundiſh red berries.

It is furniſhed with leaves all the year, flowers in May, and the whole plant effects an agreeable ſingularity.

This ſpecies being an exotic of Africa, requires ſhelter here in winter, ſo muſt be continued in pots of light earth, to be moved to a green-houſe or garden-frame in that ſeaſon, but ſhould be placed in the full air from May till October.

It propagates exceedingly by off-ſets, which may be ſeparated in September, planted ſingly in ſmall pots, and they will flower the year following.

CALTHA, Marſh Marygold.

One ſpecies only belong to this genus, a low, herbaceous, flowery perennial of but ſix or eight inches ſtature, producing many ſhowy yellow flowers.

Claſs and order, *Polyandria Polygynia*.

*Characters.*] CALIX none. COROLLA, five large, ſpreading, concave petals. STAMINA, numerous filaments, and obtuſe erect antheræ. PISTILLUM, ſeveral oblong compreſſed germina, no ſtyles, but ſimple ſtigmas. PERICARPIUM, ſeveral ſhort acuminate capſules, containing many roundiſh ſeeds.

The ſpecies is,

CALTHA *Paluſtrus*.

*Marſh Marygold.*] Caltha with fibrous perennial roots, crowned by many round crenated leaves on ſhort foot-ſtalks, and amongſt them ſeveral branching flower ſtalks ſix or eight inches high, ſurmounted by large bright-yellow flowers, in April, May, and June.

*Varieties.*] Common Single-flowered Marſh Marygold—Double Marſh Marygold.

The ſingle kinds have but five petals, but the doubles are multiplied to the very centre, forming a large, fair, full flower.

This ſpecies, in its ſingle ſtate, ornaments our moiſt meadows contiguous to brooks, rivers, or other waters, in many parts in great abundance, among which the double was found, and which merits a place among our hardy flowering perennials in the embelliſhment of ſhady borders, though it will proſper in any ſituation.

Its propagation is eaſily and abundantly effected by ſlipping or parting the roots in autumn, and each ſlip will flower the following year.

CALLICARPA, *Callicarpa*.

This is a hardy deciduous ſhrub of four or five feet ſtature, dividing low into numerous branches, garniſhed with roundiſh, acute, ſomewhat hoary leaves, and numerous ſmall, reddiſh, monopetalous, four-parted flowers in whirls, having numerous ſtamina and ſtyles.

It is proper for the ſhrubbery, and is propagated by ſeeds, layers, and cuttings.

CALYCANTHUS, Carolinian All-Spice tree.

This genus furniſhes a hardy, deciduous, aromatic ſhrub, for the ſhrubbery plantations.

Claſs and order, *Icoſandria Polygynia*.

*Characters.*] CALIX is monophyllous, cut into many ſpear-ſhaped coloured folioles. COROLLA none; the calicinal folioles ſupply the place of petals. STAMINA, many filaments, and oblong ſulcated antheræ. PISTILLUM, numerous germina, and naked ſtigmas. PERICARPIUM none; the calix thickens to an oval fruit, containing many ſeeds.

The ſpecies is,

CALYCANTHUS *Floridus*.] Calycanthus with a ſhrubby brown ſtem, branching four or

or five feet high, having an aromatic bark; large oval, pointed leaves, by pairs oppoſite; and dull-purple ſtarry flowers, placed ſingly towards the ends of the branches, having the inner petals the longeſt.

In America it has the appellation of All-ſpice, from the aromatic ſpicy odour of its bark.

This ſhrub ſhould have a warm ſituation and dry ſoil, in the fronts of the principal ſhrubbery compartments. And its propagation is by layers of the young branches, or one year's ſhoots, which in one year will be rooted fit for tranſplantation.

CALYCULA, the Calix of a floret in an aggregate flower.

CALYCULATUS *Calix*, an augmented Calix, or a flower-cup furniſhed with a leſſer flower cup, or ſmall leaves placed cloſe to the baſe of the cup, or to the flower.

CALYPTRA, the Calix of the moſſes. See CALIX.

CAMPANIFORMES *Plantæ*, plants that produce Campanulate, or bell-ſhaped flowers, ſuch as the *campanula* or bell-flower, *trachelium* or throat-wort, *convolvulus*, *lobelia* or cardinal's flowers, *aſclepias*, *atropa*, *bryonia*, *tamus*, *apocynum*, *hibiſcus*, or *altheæ frutex*, &c.

CAMPANULA, Bell-flower.

This genus furniſhes a beautiful collection of herbaceous annual, biennial, and perennial flower-plants; the perennials are much the moſt numerous, and grow from about two to ſeven feet high, garniſhed with ſimple leaves, and numerous monopetalous, very conſpicuous, bell-ſhaped, blue, purple, and white flowers.

Claſs and order, *Pentandria Monogynia*.

*Characters.*] CALIX, a monophyllous, five-parted cup placed on the germen. COROLLA, a ſingle bell-ſhaped petal, five-parted at top, and in the bottom, a five-parted Nectarium. STAMINA, five ſhort filaments inſerted into the top of the valves of the Nectarium, and oblong compreſſed antheræ. PISTILLUM, an angular germen below the receptacle, ſlender ſtyle, and tripartite ſtigma. PERICARPIUM, a roundiſh, angular capſule of three or five cells, and the ſame number of holes for the diſperſion of the ſeeds.

The ſpecies of moſt note are: the firſt four are hardy perennials.

[1]CAMPANULA *Pyramidalis.*

*Pyramidal, or Steeple Bell-flower.*] Campanula, with large, tuberous, milky roots, upright, ſtrong, ſmooth ſtalks, a yard or more high, garniſhed with oblong oval, a little ſerrated, ſmooth leaves, decreaſing in ſize upward, and numerous, large, bell-ſhaped flowers, forming a pyramid from the middle to the top of the ſtalk.

*Varieties.*] Pyramidal blue flowered Campanula——with white flowers——with double flowers.

[2]CAMPANULA *Perſicæfolia.*

*Peach-leaved Campanula.*] Campanula with very fibrey roots, crowned by numerous oboval leaves; many upright, angular ſtalks, two feet and a half high, garniſhed with long, narrow, ſtiff, cloſe-ſitting leaves, and towards the top many large, bell-ſhaped, expanded flowers in June and July.

*Varieties of this are*] Peach-leaved, ſingle, blue flowered Campanula——with double blue flowers——with ſingle white flowers——double white flowers.

[3]CAMPANULA *Trachelium.*

*Great Throat-wort, or Nettle-leaved Campanula.*] Campanula with fibrey roots, upright, angular, hairy ſtalks, two or three feet high, emitting ſhort ſide-branches, ornamented with oval, oblong, deeply ſawed, foot-ſtalked, hairy leaves; and towards the top, trifid foot-ſtalks ſupporting ſpreading bell-ſhaped flowers having hairy cups, appearing in June.

*Varieties of this are*] Great Throat-wort with ſingle blue flowers—double blue flowers—ſingle white flowers——double white flowers—ſingle and double pale purple flowers.

[4]CAMPANULA *Latifolia.*

*Great Broad-leaved Campanula, or Giant Throat-wort.*] Campanula with thick, fleſhy, milky roots, upright, ſtrong, round, taper, unbranching ſtalks, ſix or ſeven feet high, garniſhed with broad, oval-ſpear-ſhaped, ſerrated, alternate leaves, and the upper part with bell-ſhaped, deeply cut, ſpreading flowers growing ſingly on ſhort foot-ſtalks.

*Varieties.*] Great broad-leaved Campanula with ſingle blue flowers—double blue flowers—ſingle and double white flowers—ſingle and double pale-red flowers—with ſtriped flowers.

The following is a hardy biennial:

[5]CAMPANULA *Medium.*

*Middle, or Biennial Campanula, commonly called Canterbury Bells.*] Campanula with thick fibrey roots, crowned by many oblong, rough, hairy leaves; an upright, robuſt, furrowed, pyramidally branching ſtalk, two feet high, garniſhed with long, narrow, ſawed, hairy leaves, placed alternate, and numerous large bell-ſhaped, ventricoſe flowers, on long foot-ſtalks, ariſing pyramidally almoſt the whole length of the ſtalk, appearing in June and July, ſucceeded by quinquelocular capſules.

*Varieties.*] Canterbury Bell-flower with blue flowers—purple flowers—white flowers——with ſtriped flowers——with double flowers: the two latter of which are rare.

The two following are hardy annuals.

[6]CAMPANULA *Speculum.*

*Venus Looking-glaſs.*] Campanula with a very branching, diffuſed, angular ſtalk, about a foot high, ornamented with oval, oblong, cloſe-ſitting leaves, and all the numerous branches terminated each by one ſmall, bell-ſhaped, five-parted flower, in long ſolitary cups, ſucceeded by priſmatic capſules, flowering moſt part of ſummer and autumn.

*Varieties.*] Venus Looking-Glaſs with bright blue flowers—with white flowers—pale purple flowers.

[7]CAMPANULA *Hybrida.*

*Leſſer Venus Looking-glaſs.*] Campanula with a low ſtalk, eight or ten inches high, branching from the bottom, garniſhed with oblong, crenated, cloſe-ſitting leaves, and all the branches terminated by ſmall, bell-ſhaped, five-parted flowers, in aggregate cups, ſucceeded by priſmatic capſules, flowering in June and July.

The two following are green-houſe perennials.

[8]CAMPANULA *Canarienſis.*

*Canary Bell-flower.*] Campanula with thick, fleſhy, milky, penetrating roots; upright round ſtalks ſeven feet high, ſending out many ſide branches, garniſhed with ſpear-ſhaped, indented foot-ſtalked leaves, placed oppoſite, and from the joints large, perfectly bell-ſhaped, flame-coloured, reddiſh, ſtriped flowers, hanging downward, ſucceeded by quinquelocular capſules; flowering in September and October, often continuing till ſpring.

[9]CAMPANULA *Americana.*

*American Bell-flower.*] Campanula with a thick fleſhy root, crowned by a cluſtered head of oblong, crenated, rigid leaves, an upright branching ſtalk a foot and a half high, adorned with heart and ſpear-ſhaped membraneous-bordered leaves, having ciliated foot-ſtalks; and from the axillas many long pedunculi, each terminated by a large, bell-ſhaped, five-parted, ſpreading flower, in July and Auguſt.

*Varieties.*] American Bell flower with ſingle white flowers——ſingle blue—double blue.

The flowers of all the ſpecies and reſpective varieties conſiſt of only one large bell-ſhaped petal, which in different ſpecies is more or leſs five-parted and ſpreading, and which in moſt of the ſorts is ſucceeded by plenty of ſeeds in our gardens.

The firſt four ſpecies are hardy, very beautiful, flowery perennials; they are perennial only in root, which is of many years duration, crowned with numerous leaves, and amongſt them riſe the flower-ſtalks annually in ſpring, flowering chiefly in June, July, and Auguſt, ſucceeeded by abundance of ſeed, and ſoon after die down to the root; they producing numerous flowers in long ſucceſſion, renders them choice furniture for the pleaſure-ground, and grow freely in the common borders, or other compartments, in any expoſure. The firſt ſort, however, being ſomewhat impatient of wet and very ſevere froſt, ſhould have a dry ſoil and ſheltered ſituation; and ſome ſhould alſo be placed in pots, to be moved to occaſional ſhelter in ſevere weather; and in ſummer, when in flower, they may be moved in their pots to adorn any particular part, for they are very flowery and ornamental; and if their ſtalks are trained to ſticks, fan-faſhion, they will appear to conſiderable advantage, and in which order they are often placed to adorn halls and other apartments in ſummer, placing them in the chimnies, where they will continue a long time ornamental.

The fifth ſort *(Campanula Medium)* and varieties are moſt elegant biennials, and fine furniture for any part of the pleaſure-ground; but as being biennials, never flower but once, they riſing from ſeed one year, the next they ſhoot up ſtalks, flowers, and perfect ſeeds, and ſoon after totally periſh; ſo that a ſupply muſt be annually raiſed from ſeed.

The two annual ſorts are proper furniture to adorn the fronts of borders, on the ſides of ſpacious walks, in patches, among other hardy annuals. See ANNUAL PLANTS.

The two green-houſe ſorts are plants of ſuperior beauty when they flower, particularly the *Campanula Canarienſis.* The roots of both are durable, but the leaves and ſtalks are renewed annually, and flower freely, but rarely afford us ſeeds in England: they muſt be kept in pots of light earth, and moved to the ſhelter of a green-houſe or garden-frame in winter.

### *Propagation of all the Sorts.*

The firſt four ſpecies and varieties are propagated plentifully by ſlipping or parting their roots in September, October, or early in ſpring. They may be alſo raiſed abundantly by ſeed, in a bed or border of common earth in March, ſowing it on the ſurface, and rake it in; and the plants ſhould be pricked out in July,

July, which in October or November tranſplant into the borders, where they will flower the following ſummer. But as there ſeldom riſe any but ſingle flowers from ſeeds, the double kinds therefore are increaſed with certainty no other way than by dividing the roots, every off-ſet or ſlip of which having fibres will readily grow; but it is not proper to part them too ſmall, unleſs when intended to have as great an increaſe as poſſible, in which caſe the ſmall ſlips ſhould be planted in nurſery-beds a year to get ſtrength; but the large ſlips may be planted at once, where they are to remain to flower.

But it is proper to obſerve of the firſt ſort (*Pyramidal Campanula*), that the roots do not multiply ſo faſt as the others, nor are they of ſo long duration; it is therefore neceſſary to raiſe a ſupply of them often from ſeed, and ſeedling-plants generally flower ſtrongeſt. Let ſeeds therefore be ſown in autumn, or early in ſpring, in large pots, boxes, or tubs of light rich compoſt, covering the ſeed half an inch deep, and place them in a frame to have occaſional ſhelter of glaſſes in very cold, wet, or ſevere froſty weather, but fully expoſe them in mild days. By this care the plants will appear in April or May, and by September will be of due ſize to tranſplant, doing it when their leaves decay, planting them in a high-lying bed or border of light earth, at ſix inches diſtance, with their crowns half an inch deep. Here let them remain two years, giving occaſional ſhelter in winter, and weeding and water in ſummer; then in autumn finally tranſplant them, ſome into pots, others cloſe under a warm wall, and ſome diſperſe in open dry borders among other perennials.

The fifth ſort (Canterbury-bell) and varieties, being biennials, can only be raiſed from ſeed, ſown annually in March, April, or May: ſow it in a bed or border of good earth by broad-caſt, and rake it in, and the plants will be fit to prick out in June or July, planting them ſix inches apart, to remain till autumn or ſpring following; then tranſplant them, with little balls of earth to their roots, in the places where they are to flower.

The two annual ſorts are alſo raiſed from ſeed, ſowing it a quarter of an inch deep, in ſmall patches, in different parts of the borders, in the place where they are to flower, permitting ſeveral plants to remain in each patch.

The Canary Campanula is propagated by off-ſets of the roots in July, when the ſtalks decay; theſe being ſucculent milky roots, it is neceſſary, when you ſlip them, that the ſlips lie ſeveral days in the dry, to heal over the wounded parts; then plant them ſingly in pots of light ſandy earth, place them in the ſhade, and moiſten the earth occaſionally in dry weather.

The American ſort is alſo propagated by off-ſets from the roots of the old plants in September.

CANNA, Indian flowering Reed, or Indian Shot, ſo called from the figure of their black ſeeds.

The plants are herbaceous perennials of America, preſerved here in hot-houſes for the beauty of their monopetalous flowers, produced in ſpikes upon ſtalks, from about a yard to ſix or ſeven feet high.

Claſs and order, *Monandria Monogynia.*

*Characters.*] CALIX, a three-leaved coloured abiding cup. COROLLA, one petal cut into ſix ſpear-ſhaped ſegments, and a two-parted nectarium. STAMINA, no filaments, but a linear antheræ, attached to one ſegment of the nectarium. PISTILLUM, a roundiſh germen under the Calix, a flat ſtyle, and linear ſtigma. PERICARPIUM a roundiſh, three-furrowed, trilocular capſule, containing globular ſeeds.

The ſpecies are,

[1] CANNA *Indica.*

*Common Indian Flowering Reed.*] Canna with a tuberous, thick, fleſhy root, crowned by many large, oval, ribbed leaves, a foot long, almoſt half as broad, pointed at both ends, and an upright herbaceous ſtalk four feet high, terminated by looſe ſpikes of flowers, of different colours in different varieties.

*Varieties are*] Common Indian Flowering Reed with ſcarlet flowers—red flowering—yellow flowering—and with ſpotted flowers.

[2] CANNA *Glauca.*

*Glaucous, or Sea-green-leaved Canna.*] Canna with tuberous, knotty, fleſhy roots, upright ſtalks ſeven feet high, leaves a foot and a half long, and the ſtalk terminated by thick ſpikes of large, pale, yellow flowers.

Theſe plants make a good appearance when in flower, which in England is in June, July, and Auguſt, ſucceeded by ſeeds in autumn. The plants muſt always be kept in pots of rich earth, to be moved to ſhelter in winter.

They are propagated by ſeeds in a hot-bed in ſpring; and in ſummer, when the plants are a little advanced in growth, prick them ſeparately in ſmall pots of rich earth, plunging them alſo in the hot-bed, giving ſhade, water, and freſh air, to which harden them by;

by degrees till they bear it fully till October, then place them in a ſtove or very good green-houſe.

CANNABIS, the Hemp Plant.

There is but one ſpecies, an herbaceous, tall, ſtrong annual, valuable for the bark of its ſtalk for making hemp for cordage and coarſe cloth, and for its ſeed for oil, &c.

Claſs and order, *Dioecia Pentandria.*

*Characters.*] CALIX, male and female flowers on different plants, the males having a five-parted cup; that of the females is monophyllous, oblong, pointed, and permanent. COROLLA, no petals. STAMINA, the males have five filaments, and ſquare antheræ. PISTILLUM, a ſmall germen, two long ſtyles, and acute ſtigmas. PERICARPIUM, it is very ſmall, and the ſeed is lodged in the calix.

The ſpecies is,

CANNABIS *Sativa.*

*Manured Hemp.*] Cannabis with upright, ſtrong, branchy ſtalks, ſix or ſeven feet high, adorned with large finely-digitated leaves, of about ſeven long narrow lobes.

*Varieties.*] Manured Hemp with male flowers——with female flowers, or female hemp.

Both the varieties are alike uſeful, as hemp for cordage, &c. but it is the female ſort only, that produce the ſeed, for oil and other uſes.

A few of theſe plants may be admitted as annuals in the pleaſure-ground, for the variety of their majeſtic growth and numerous fingered leaves, ſowing the ſeed in April where the plants are deſigned to remain.

In the huſbandry culture of this plant, it delights in a moiſt, rich, deep ſoil, prepared for the ſeed, by ploughing and harrowing; and April is the time for ſowing, allowing two buſhels to an acre, ſowing it by broadcaſt and harrow it in; and when the plants are come, hoe them to a foot diſtance, and they will be fit to pull for uſe in autumn.

It is pulled at two different times, the male plants generally about the middle of Auguſt, or when they have ſhed their farina to fecundate the females, ſoon after which they begin to decay, and ſhould be pulled; but the females muſt ſtand till October to ripen their ſeed. Both ſorts, when pulled, are bound in bundles a yard in compaſs, and after drying a few days, are ſtacked up or houſed for uſe.

CAPITULUM, a little roundiſh head of flowers, a mode of infloreſcence, or way of flowering, in which many ſmall flowers or florets are collected into a cloſe roundiſh head or knob, appearing as one flower, as in *gomphrena*, or globe amaranthus; and *cephalanthus*, or button-tree.

A *Capitulum* is either,

*Globoſum*, round or globular, as in *gomphrena globoſa*; *dimidiatum*, half globular or hemiſpherical; *ſubrotundum*, roundiſh; *ovatum*, egg-ſhaped; *pyramidatum*, pyramidal ſhaped; *pedunculatum*, the florets having little foot-ſtalks; *folioſum*, leafy, or intermixed with leaves; *nudum*, naked, having no leaves; *hiſpidum*, hiſpid, briſtly.

CAPPARIS, the Caper Shrub.

There are ſeveral ſpecies, moſtly of ſhrubby growth; one of which is cultivated in many of our gardens as a green-houſe plant, and which is the true Caper-Shrub, a native of Italy, the flower-buds of which pickled, are the Capers uſed in ſauces, &c.

Claſs and order, *Polyandria Monogynia.*

*Characters.*] CALIX, the cup is cut into four concave gibbous parts. COROLLA, four large, obtuſe, ſpreading petals. STAMINA, numerous filaments, and verſatile antheræ. PISTILLUM, a pedicillated germen, no ſtyle, but an obtuſe ſeſſile ſtigma. PERICARPIUM, a fleſhy, pedicillated, unilocular berry, and numerous ſeeds.

The true Caper is,

CAPPARIS *Spinoſus.*

*Spinous Capparis, or True Caper-Shrub.*] Capparis with ſhrubby ſpinous ſtalks and branches, forming a buſhy head, growing three or four feet high, garniſhed with roundiſh, ſmooth, entire leaves, placed alternate; and from the ſides of the branches many ſingle foot-ſtalks, each ſuſtaining one large, expanded, white flower.

The flower-buds, before the petals begin to expand, are proper for Capers; but for which uſe theſe are not to be expected in due quantity in this country.

This plant muſt be kept in pots of light ſandy earth, to be placed in a green-houſe in winter; but it is generally more prolific in flowers, when in a hot-houſe during that ſeaſon.

It is propagated by ſeed from abroad; and by layers of its youngeſt branches: ſow the ſeeds in pots of light ſandy compoſt in ſpring, and plunge them in a hot-bed. By layers, the young branches may be layed in ſpring or ſummer, giving each a ſmall ſlit, and they will probably be rooted in a year, though they are often two before it is effected.

CAPSICUM, *Capſicum*, or Guinea Pepper.

This genus furniſhes ornamental and uſeful plants, conſiſting of herbaceous tender annuals, and ſhrubby hot-houſe perennials, all of upright growth, with branchy heads, from two to five feet high, garniſhed with ſimple leaves, and ſmall wheel-ſhaped, five-parted, white flowers, ſucceeded by elegant ſcarlet, or yellow fruit; in which conſiſts the principal merit of the plants, being beautiful when growing, and are an excellent pickle, of a hot ſpicy nature.

Claſs and order, *Pentandria Monogynia.*

*Characters* ] CALIX, a monophyllous cup, divided into five erect permanent ſegments. COROLLA, a ſmall wheel-ſhaped acutely five-parted patent petal. STAMINA, five filaments, and connivent antheræ. PISTILLUM, an oval germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, the germen ſucceeds to a baccaceous, hollow, bilocular fruit, of uncertain figure, furniſhed with numerous compreſſed ſeeds.

Modern botaniſts allow but two real ſpecies of this genus, an herbaceous annual, and a ſhrubby perennial; but both of which vary wonderfully into numerous varieties, in regard to the ſhape, ſize, and poſition of growth of the fruit.

The ſpecies are,

[1]CAPSICUM *Annua.*

*Annual Herbaceous Capſicum.*] Capſicum with an upright herbaceous ſtalk, dividing into a branchy head, about two feet high, garniſhed with long, broad, entire leaves; and from the ſides of the branches numerous ſmall, wheel-ſhaped, quinquefid, white flowers, ſucceeded by beautiful ſcarlet or yellow pods, of an indeterminate figure and ſize, from half an inch to half a foot long.

The varieties of this, in reſpect to the ſhape, ſize, and poſition of growth of the fruit, are very numerous, which may be divided into ſix claſſes, as thoſe of each claſs are pretty permanent.

Varieties are,

*Long-podded Annual Capſicum.*] Capſicum with oblong, pendulous or hanging, ſcarlet pods——with oblong, pendulous, yellow pods——with upright, oblong, ſcarlet pods——with ſhort upright pods——with divided pods——with very taper pods a ſpan long.—All of which varieties often riſe from the ſame ſeed of the Common Long-podded, Red, or Yellow Capſicum, rarely altering from one to the other in colour, only in the ſize and poſition of growth.

*Heart-ſhaped Capſicum.*] Capſicum with roundiſh, heart-ſhaped, hanging pods——with oblong, heart-ſhaped, hanging pods——with heart-ſhaped upright pods—with round, heart-ſhaped, upright pods——with very large roundiſh upright pods, of each of which there are red and yellow colours.

*Angular heart-formed Capſicum.*] Capſicum with upright, angular, heart-ſhaped, furrowed and wrinkled ſcarlet pods——with upright, angular, heart-ſhaped, flat-topped, ſcarlet pods——with upright, angular, bell-ſhaped, ſcarlet pods; and the plants have generally broad wrinkled leaves.

*Great Angular Pickling Capſicum, or Bell Pepper.*] Capſicum with upright, ſwelling, fleſhy-ſkinned, wrinkled red pods, flatted and angular at top——with hanging or pendulous pods; the pods of theſe varieties having a thicker, more fleſhy, and tender ſkin, are the beſt of all for pickling.

*Cherry-fruited Capſicum.*] Capſicum with low ſpreading branches, leaves in cluſters, and round, ſmooth, red, cherry ſhaped fruit.

*Olive-ſhaped Capſicum.*] Capſicum with an erect branchy head, and olive-ſhaped fruit.

Each of the above claſſes of varieties, though allowed to be only varieties of one common parent, yet by care in ſaving the ſeeds of the plants of each claſs, they continue pretty diſtinct or permanent, and ſeeds of either generally produce the like kinds, as expreſſed under each head.

All the varieties flower in June and July, and the pods and ſeeds ripen in Auguſt, September, and October.

The following are the ſhrubby perennial ſpecies and varieties.

[2]CAPSICUM *Fruteſcens.*

*Shrubby Perennial Capſicum.*] Capſicum with a ſhrubby perennial ſtem, divided into a branchy, buſhy head, four or five feet high, garniſhed ſome with long narrow, and others with broad, and with purple veined leaves, and ſmall wheel-ſhaped, five-parted, white flowers, ſucceeded by many very ſmall fruit of different figures in different varieties.

*Varieties of this are*] Shrubby perennial Capſicum, with pyramidal yellow fruit——Shrubby, pyramidal, red, barberry-fruited Capſicum, or barberry pepper—Shrubby, conical red-fruited Capſicum, or hen pepper—Shrubby, conical, golden-fruited Capſicum ——Shrubby, oval, very ſmall, red-fruited Capſicum, or bird pepper: all theſe, though ſuppoſed only varieties of the ſame ſpecies, are pretty permanent from ſeed, i. e. the ſeed

of any particular variety, if ſaved with care, generally produce plants and fruit of the ſame kind.

All theſe plants, both annual and ſhrubby kinds, being natives of both Indies, are conſequently of tender quality here. The annuals require to be raiſed and forwarded in hot-beds, raiſing them from ſeed in March or April, and continuing them under occaſional ſhelter until the end of May, or beginning of June. And the ſhrubby kinds require almoſt the conſtant temperature of a ſtove, or, at leaſt, although they will ſucceed in a moderate hot-bed under a deep frame in ſummer, where they can have occaſional ſhelter of glaſſes in nights and bad weather: they muſt be placed in a ſtove in autumn, to remain all winter.

The annual kinds in general, conſidered as plants of ornament, are of a regular branchy growth, and very flowery; but their greateſt merit is in the beauty of their fruit, which being numerous, and of different forms, ſizes, poſitions of growths, and colours, intermixed with the green leaves and white flowers, make a fine appearance the latter part of ſummer, either in the borders, &c. or in pots to adorn courts or other compartments.

And for uſeful purpoſes, the young or half-grown fruit is eſteemed the fineſt pickle in the world; all the ſorts may be uſed for this purpoſe, but the great angular-podded kind claims preference.

The ſhrubby ſorts make a fine appearance in autumn and winter in the ſtove, with their ripe fruit, and which often continues on the plants till ſpring.

The pods of all the ſorts are very hot and ſpicy: the inhabitants of America uſe them in all their ſauces, and the negroes devour them greedily; whence the plants have the appellation of Negro, or Guinea Pepper.

The ripe ſeed of all the ſorts is inſupportably acrid, as many have experienced by ignorantly chewing it, or by waggiſh perſons rubbing it, for diverſion, on the edges of drinking cups, &c. And the ripe pods thrown in the fire, occaſion vehement ſneezing, coughing, and frequently vomiting.

*Propagation of all the Sorts.*

All the ſorts are eaſily raiſed from ſeed, in a hot-bed, in March or beginning of April. But firſt of the annual ſorts.

A hot bed is to be prepared at the above time, which will ſerve for theſe and many other tender annuals, place a frame and glaſs thereon, and then lay in five or ſix inches depth of rich light earth; the ſeed may then either be ſown on the ſurface, or in ſmall drills, or in pots, plunging them in the mould, obſerving in either method to cover it about a quarter of an inch deep: the plants will ſoon appear, obſerving to give air daily in common with other plants of the bed, by tilting up the light. See ANNUAL PLANTS. Alſo give frequent very moderate waterings; and when they are two or three inches high, having three or four leaves, it will be of much advantage to prick a quantity of them out upon another hot-bed, at four inches diſtance, giving water, and ſhade them occaſionally from the ſun, till rooted; after which admit air freely every favourable day, and moderate waterings two or three times a week; and by the middle of May harden them gradually to the full air, into which they ſhould be tranſplanted the beginning of June, removing them with a ball of earth to each root, and place ſome in different parts of the flower-borders, and ſome in pots, giving due waterings in dry weather, till they have taken good root.

But thoſe you intend for pickling, ſhould be planted out in a rich warm border, in the kitchen-garden, in rows a foot and a half or two feet diſtance, and about fifteen inches diſtant in the line, giving water as above directed.

The ſhrubby ſorts are alſo raiſed from ſeeds, as directed for the annuals, and the plants ſhould be pricked ſingly in ſmall pots, and plunged upon another hot-bed, under frames and glaſſes, giving air and water as before obſerved; and when they are conſiderably advanced in growth, remove them, with the balls to their roots, into larger pots, plunging them alſo in a moderate warmth under a deep frame, where they may remain to have occaſional ſhelter of the glaſſes till autumn; then remove them in their pots to the ſtove, where their fruit will form a fine variety all winter.

**CAPSULA**, Capſule, one of the eight ſpecies of pericarpium, or ſeed-veſſel.

This ſpecies of ſeed-veſſel, *Capſula*, is a dry hollow pericarpium, of one or more elaſtic valves, which opens or ſplits, in ſome determinate manner, for diſcharging the ſeeds when ripe, and differs eſſentially from the other ſeven ſpecies of ſeed-veſſel. See PERICARPIUM, &c.

A Capſule conſiſts of one or more cells, *Locu-*

[*Loculamenta*] when of two or more, they are divided from each other by partitions, having a *Columnella*, or little column of membraneous ſubſtance, paſſing through it, to connect the ſeveral partitions with the ſeed. When the Capſule conſiſts of a ſingle cell only, it is botanically termed *unilocular*; if of two, *Bilocular*; if three, *trilocular*; if four, *quadrilocular*; if five, *quinquelocular*; if ſix, *ſexlocular*; and if many, *multilocular*.

When it is compoſed of two valves, or parts that open, it is termed *bivalve*; when of three, *trivalve*; when of four, *quadrivalve*; and of five, *quinquevalve*, &c. See VALVULA.

When of different figures, they are termed *trigona*, when three-cornered; *tetragona*, four-cornered; *pentagona*, five-cornered; *turbinata*, top-ſhaped; *inflata*, ſwoln or puffed out; *ventricoſa*, big-bellied; *flaccida*, feeble, flaccid; *globoſa*, round, globular; *ovata*, egg-ſhaped; *cordata*, heart-ſhaped; *obcordata*, heart-ſhaped, with its tip downwards; *columnaris*, column-ſhaped; *acuminata*, pointed, tapering to a point; *teres*, ſlender and cylindrical; *conica*, conic-formed; *bicornis*, two-horned; *tricornis*, three-horned; *lunalata*, creſcent-ſhaped; *compreſſa*, flat, preſſed together; *lanceolata*, lance-ſhaped; *ſubrotunda*, roundiſh; *oblonga*, oblong, longer than broad; *bicarinata*, two-keeled; *tricarinata*, three-keeled; *alata*, winged; *ſucculenta*, ſucculent, pulpy; *carnoſa*, fleſhy; *lignoſa*, woody ſubſtance; *coriacea*, leathery ſubſtance; *membranacea*, membraneous, of thin dry membranes; *didyma*, twin capſules; *emarginata*, notched in the margin; *biſulcata*, two-furrowed; *triſulcata*, three-furrowed; *ſtriata*, ſtreaked, or ſuperficially furrowed; *glabra*, ſmooth; *echinata*, (hedge hog) prickly; *tomentoſa*, downy, *hiſpida*, briſtly or ſhaggy; *nuda*, naked, oppoſed to *hiſpida*; *pellucida*, pellucid, or tranſparent; *colorata*, coloured, as in *celaſtrus*; *elaſtica*, elaſtic, burſting elaſtically like a ſpring, and darting the ſeeds from their departments with great velocity, as in ſome ſpecies of *impatiens*, or balſamine, and many others. See ELASTICA.

The number of Capſules ſucceeding each flower, is generally the ſame as the *germina*, or ſeed-bud; for the Capſule and all other ſeed-veſſels is nothing elſe than the ſeed-bud, or germen, arrived at maturity. See GERMEN. The ſeed-veſſel therefore conſiſts either of one Capſule, as in lychnis; two, as in pœony; three, as in lark-ſpur; four, as in rhodiola, or roſe-root; five, as in columbine, &c.

Capſules in ſplitting, or opening, are divided externally into one or more pieces, or openings, called *valves*. See VALVULA. This opening of the Capſule for diſcharging the ſeeds when ripe, is ſometimes at the baſe, ſometimes on the ſide, through a ſmall hole, as in *campanula*; in ſome horizontally; and in ſome longitudinally, as in *convolvulus*; but the moſt uſual opening, in moſt plants, is at the top, and burſt in as many different ways as there are valves.

CARDAMINE, Ladies Smock, or Cuckoo flower.

It compriſes ſome low, herbaceous, flowering perennials of ornamental appearance, proper for adorning the pleaſure ground.

Claſs and order, *Tetradynamia Siliquoſa*.

*Characters.*] CALIX, four oval, oblong, deciduous leaves. COROLLA, four oblong cruciforme petals, the lower part erect, and ſpreading above. STAMINA, ſix filaments, four the length of the calix, and two much longer, and heart-ſhaped erect antheræ. PISTILLUM, a cylindric germen, no ſtyle, but a capitated ſtigma PERICARPIUM, a long, cylindric, compreſſed, bilocular pod, opening ſpirally, and darting out the ſeeds with elaſtic force.

There is but one ſpecies that have claim to attention, which admits of ſome varieties, which are,

CARDAMINE *Pratenſis*.

*Common Meadow Ladies Smock* ] Cardamine with creeping ſtringy roots, crowned by many winged roundiſh-lobed leaves, ſpreading on the ground, and ſeveral ſmall ſtalks, a foot high, garniſhed with lanceolate-lobed leaves, and many flowers, in May and June.

*Varieties of this are*] Common Ladies Smock with ſingle purple flowers——with double purple flowers——ſingle white flowers——with double white flowers.

The flowers of the ſingle kind have four petals, but thoſe of the double ſorts are multiplied to the very center. The ſingle ſorts embelliſh the meadows in great abundance in May, from whence the double ſorts were firſt accidentally obtained, which are highly ornamental and proper furniture for the flower-borders, and will proſper in any ſituation, but delights moſt in moiſt ſhady places, where they generally produce larger, more beautiful, and durable flowers. They are all eaſily

propagated by ſlipping or dividing the roots in autumn or early in ſpring, and all the ſlips, if not parted very ſmall, will readily flower the following May.

CARDUUS, the Thiſtle.

It comprehends many hardy herbaceous annuals, biennials, and perennials, growing from one to five or ſix feet high, having compound flowers in ventricoſe, ſcaly, very prickly cups, but being moſtly very troubleſome weeds, are rarely admitted in gardens.

CARDUUS *Benedictus*. See CENTAUREA.

CARICA, the Papaw, or Pepo-tree.

This genus furniſhes two curious hot-houſe exotics of tree-like growth, adorned with beautiful, large, divided leaves, and monopetalous and quinquepetalous, white, yellow, and purple flowers, ſucceeded by very large, fleſhy, eatable fruit.

Claſs and order, *Dioecia Decandria*.

*Characters.*] CALIX, male and female flowers on ſeparate plants, the males having ſcarce any cup, and the females a ſmall permanent one, quinquefid at top. COROLLA, the males a funnel-ſhaped, long, tubular petal, cut into five narrow, blunt, revolute ſegments; and in the females five long ſpear-ſhaped petals turned back at top. STAMINA, ten filaments, five of them alternately ſhorter than the other, and oblong antheræ. PISTILLUM, an oval germen, very ſhort ſtyle, and five broad crenated ſtigmas. PERICARPIUM, a large, oblong, fleſhy, baccaceous, unilocular fruit, full of ſmall oval ſeeds.

The ſpecies are,

[1]CARICA *Papaya*.

*Common Indian Papaw.*] Carica with an upright, thick, ſoft, hollow, naked ſtem, riſing twenty feet high, garniſhed upward with very large, divided, deeply ſinuated-lobed leaves, ſpreading two or three feet on every ſide, and male flowers in white cluſters on long foot ſtalks, yellow or purple female ones growing cloſe round the ſtem, ſucceeded by very large, fleſhy, yellow, different-ſhaped fruit.

*Varieties.*] Common Papaw with male flowers—with female flowers,—With melon-ſhaped fruit—with gourd-ſhaped fruit——with pear-ſhaped fruit—with pyramidal fruit.

[2]CARICA *Poſopoſa*.

*Branching Surinam Papaw.*] Carica with an upright branching ſtem twenty feet high; large divided leaves, having entire lobes, ſpreading widely every way; and reddiſh male flowers in cluſters, and female ones cloſe to the ſtem, ſucceeded by very large, pear-ſhaped, yellow fruit.

Both the ſpecies produce male and female flowers on ſeparate plants, ſo that the female plants only produce the fruit.

All the varieties are very ornamental in their beautiful, very large, many-lobed leaves, making a fine appearance in the ſtove at all ſeaſons, and ſome of them flower here annually; and thoſe of the females are ſucceeded by ripe fruit, which, however, ſeldom ripen in perfection enough to be eatable.

Theſe plants are propagated by ſowing the ſeed in a hot-bed in March or April, and when the plants are two inches high, prick them in ſeparate ſmall pots of light rich earth, and plunge them in a bark-bed; and towards autumn place them in the ſtove to remain, giving but very light waterings in winter, but in ſummer it muſt be frequently repeated; and as the plants advance in growth, ſhift them into larger pots; at each ſhifting be careful to preſerve the ball of earth to the roots.

The plants are free ſhooters; and in this country they often attain from ten to twenty feet ſtature in three or four years.

CARPINUS, the Hornbeam-tree.

This genera furniſhes two ſpecies and ſome varieties of hardy deciduous foreſt and ornamental trees, of ſtature from ten to ſeventy feet, garniſhed with ſimple oblong leaves, and amentaceous or katkin flowers.

Claſs and order, *Monoecia Polyandria*.

*Characters.*] CALIX, male and female flowers apart on the ſame plant, growing each in a looſe ſcaly amentum, each ſcale containing one flower. COROLLA, no petals in the males, but a cup-ſhaped ſix parted corolla in the female katkins. STAMINA, ten filaments, and compreſſed hairy antheræ. PISTILLUM, two ſhort germens, four ſtyles, and ſimple ſtigmas. PERICARPIUM, none; the amentum enlarges, containing at the baſe of each ſcale an oval angular nut.

The ſpecies are,

[1]CARPINUS *Betulus (Vulgaris.)*

*Common Hornbeam.*] Carpinus with an upright ſtrait ſtem from thirty to ſeventy feet ſtature, feathered from the bottom, and terminating in a very branchy head, adorned with oval, oblong, rough leaves, withering in autumn, but remain firmly attached to the branches till ſpring, and with plane ſcales to the cones, furniſhing abundance of ripe ſeed in autumn.

*Varieties*

*Varieties of this are*] Common Hornbeam with plain green leaves—Variegated-leaved Common Hornbeam——Virginia Hornbeam growing thirty or forty feet high, closely garnished with longish, rough, deep-green leaves, falling off in autumn, and the longest cones——Oriental Hornbeam growing ten or twelve feet high, closely branching from the bottom horizontally, garnished with oval spear-shaped leaves, and very short cones.

[2]CARPINUS *Ostrya.*

*Ostrya, or Hop Hornbeam.*] Carpinus with an upright stem, attaining twenty feet stature, terminating in a regular head, garnished with oval, oblong, rough leaves, and hop-like fruit, having inflated scales.

*Variety.*] Virginian Flowering Hop-Hornbeam growing thirty feet high, having long rough leaves and yellowish flowers, succeeded by hop like fruit.

All the varieties of both these species of *Carpinus* are very hardy, and will prosper in almost any soil and exposure, and of which there are varieties well adapted both for use and ornament.

As to the Common Hornbeam, it flourishes not only in good ground, but in any hungry barren soil, light or stiff, as well as in all hilly and other bleak exposed places, and is very proper to be planted as a forest tree, and for ornament in parks, either as single standards, or in clumps or large plantations; and as it retains its leaves all winter, it affords shelter to less hardy trees, and is therefore well adapted to border plantations, to break the northerly and boisterous winds.

This tree is also remarkably well adapted for hedges, either by way of ornament or shelter, for it is feathered to the very bottom, and may readily be trained to any desired height.

As the timber of this tree is valuable for many œconomical uses, a wood of them may be easily raised on any soil to advantage, planting four or five year old plants in rows four or five feet distance, and half that in the lines, and after a few years growth every other tree in the row may be thinned for use, so continuing to thin them as often as their heads touch.

The other sorts are also very proper for large ornamental plantations to encrease the variety, and the oriental kind is particularly well adapted for low close hedges; all the others, being also generally pretty well feathered, may also be used occasionally for that purpose.

*Propagation of all the Sorts.*

The common sort may be raised plentifully from seed sown in autumn in four feet wide beds, covering it an inch deep, and in the second spring the plants will rise, which in a year or two should be transplanted in the nursery, in rows two feet and half distance, and half that in the rows; and when from three to six or eight feet high, are fit for any plantation, useful and ornamental.

This sort may also be raised abundantly by layers in autumn, which will be rooted and fit to transplant by that time twelvemonth.

All the other sorts may also be raised easily from seed and layers, but the latter method is the only way to continue the different varieties distinct.

CARTHAMUS, Bastard Saffron.

The plants of this genus consists of some ornamental herbaceous annuals and perennials, producing stalks two or three feet high, crowned by yellow and blue compound flowers.

Class and order, *Syngenesia Polygamia Æqualis.*

*Characters.*] CALIX, a compound flower, having the general cup composed of many leafy scales broad at the base. COROLLA is composed of many hermaphrodite florets, divided at top into five erect segments. STAMINA, five short filaments, and cylindric tubular antheræ. PISTILLUM, a short germen, slender and simple stigma. PERICARPIUM, none; a single seed in each floret lodged in the calix.

The species are,

[1]CARTHAMUS *Tinctorius.*

*Dyer's Carthamus, or Common Bastard Saffron.*] Carthamus with an upright, smooth, branchy stalk a yard high, garnished with oval, entire, spiny serrated, close-sitting leaves, and all the branches crowned by large single heads of saffron-coloured florets, extending an inch above the calix.

The flowers of this species are used in dying, and for medicinal purposes.

[2]CARTHAMUS *Lanatus.*

*Woolly Carthamus, or Yellow Distaff Thistle.*] Carthamus with bottom leaves, pinnatifid, hairy, and prickly; an upright woolly stalk two feet high, branching above, garnished with sinuated, hairy, spinous leaves, their base embracing the stalks, and all the branches surmounted by single heads of yellow flowers.

[3]CARTHAMUS *Cæruleus.*

*Blue Perennial Carthamus* ] Carthamus with upright,

upright, channelled, ſingle ſtalks, two feet high; broad, ſpear-ſhaped, indented, ſpinous leaves; and one blue flower terminate each ſtalk.

[4]CARTHAMUS *Tingitanus.*

*Tangier Blue Perennial Carthamus.*] Carthamus with the radical leaves pinnated; upright ſlightly branching ſtalks a foot and half high, garniſhed with pinnatifid prickly leaves, and one blue flower terminates each ſtalk.

The flowers of all the ſorts are compound, conſiſting of many florets in very large, leafy, ſcaly, cups, which, in all the ſorts, appear in July and Auguſt, and the ſeed ripens in autumn: they all ſucceed in the open borders, and will add to the variety of flowering plants.

The two firſt ſorts are hardy annuals, and may be ſown in March in the places where it is deſigned they ſhall flower; or if ſown in a hot-bed it will forward them, ſo plant them out in May.

The two perennial ſorts are propagated by parting their roots in autumn or ſpring; or by ſeeds in a bed of light earth in March.

CARUM, *Carvi*, or Caraway.

It compriſes but one ſpecies, an herbaceous, umbelliferous, aromatic biennial, eſteemed for its ſeeds for cookery and medical uſe.

Claſs and order, *Pentandria Digynia.*

*Characters.*] Umbelliferous flowers, each general umbel compoſed of ten ſmaller, and each floret of five petals, having five ſtamina, two ſtyles, and two ſeeds.

The ſpecies is,

CARUM *Carvi.*

*Common Carvi, or Caraway.*] Carum with a long, taper, perpendicular, white root, crowned by winged, finely, many-parted leaves, on long foot-ſtalks, and one or two erect, channelled, branchy ſtems, two feet high, having all the branches terminated by umbels of white flowers in June, and ripen ſeeds in autumn.

It is propagated by ſeed in the open ground in ſpring or autumn, ſowing them either in ſhallow drills, or by broad-caſt, and rake them in; and when the plants are come up two or three inches high, hoe them to five or ſix inches diſtance, which in ſpring following will ſhoot up ſtalks, and produce flowers and ſeed, and the plants ſoon after periſh.

If the ſeeds are ſown in autumn, the plants will come up, ſtand the winter, and produce ſeeds the following ſummer.

CASSIA, Wild Senna.

It conſiſts of trees, ſhrubs, and herbaceous plants, of American growth, adorned with winged many-lobed leaves, and quinquepetalous flowers, cultivated here in our ſtoves and pleaſure-grounds for variety.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, five concave-coloured deciduous leaves. COROLLA, five roundiſh, concave, patent petals. STAMINA, ten declinated filaments, having to the three lower ones large, arched, beaked, open-pointed antheræ, which in the three upper ones are very ſmall, and in the four ſide ones open without beaks. PISTILLUM, a taper germen, ſhort ſtyle, and blunt ſtigma. PERICARPIUM, an oblong pod, having tranſverſe partitions, containing roundiſh ſeeds.

The ſpecies chiefly cultivated in our gardens are,

[1]CASSIA *Fiſtula.*

*Purging Tree-Caſſia of Alexandria.*] Caſſia with an upright trunk, dividing into many branches, and attains forty or fifty feet ſtature; winged leaves of five pair of oval ſharp-pointed lobes; and from the ends of the branches long ſpikes of deep yellow flowers, ſucceeded by round hard pods one or two feet long, containing the ſeeds lodged in a black, ſweetiſh, purging pulp, uſed in medicine.

[2]CASSIA *Biflora.*

*Two-flowered Shrub-Caſſia.*] Caſſia with ſhrubby ſtalks and branches three or four feet high; winged leaves of ſix pair of oblongiſh ſmooth lobes, having ſubulated glands between, and foot-ſtalks from the axillas, each ſupporting two flowers, ſucceeded by jointed plane pods.

[3]CASSIA *Ligufirina.*

*Privet-lobed Shrub Caſſia.*] Caſſia with a ſhrubby ſtalk, branching three or four feet high; winged leaves of ſeven pair of ſmall ſpear-ſhaped lobes or folioles, the laſt pair the ſmalleſt; and from the upper parts, bunches of yellow flowers, ſucceeded by oblong compreſſed ſeed-pods.

[4]CASSIA *Marilandica.*

*Maryland Herbaceous Wild Senna.*] Caſſia with black, fibrey, perennial roots; upright annual ſtalks near a yard high; winged leaves of eight or nine pair of oval oblong lobes; and the ſtalks terminated by looſe ſpikes of yellow flowers, but rarely any ſeeds here.

The flowers of all the ſorts ſeparately are compoſed of five concave petals, appearing in July, and other times in ſummer, ſometimes ſucceeded by pods in England.

The

The firſt three ſorts being natives of warm climates, in this country muſt be potted, and retained always in the ſtove; the firſt of which, *(Caſſia Fiſtula)* though in its native ſoil, Ægypt and India, it obtains a conſiderable ſtature, rarely grows higher than eight or ten feet here; ſo that this and the other two ſhrubby ſorts are within the limits of our ſtoves, where they will flower annually and make a good appearance, and their long pods will effect a ſingular variety.

The above three plants ſhould be kept in pots of light earth, plunged in the bark-bed of the ſtove, giving frequent waterings in ſummer, but more ſparingly in winter.

The fourth ſort *(Caſſia Marilandica)* is hardy enough to proſper in a dry ſoil in the full air, and is proper furniture for the common flower-borders, where its flowers will make a beautiful appearance.

*Propagation.*

The firſt three ſhrubby ſorts are raiſed from ſeeds procured from abroad, ſowing them in ſpring in pots of light ſandy earth, plunging them in a hot-bed, and when the plants are three inches high, prick them in ſeparate ſmall pots, plunging them alſo in a hot-bed or bark-bed of the ſtove, giving ſhade and water, and freſh air occaſionally, in common with the other plants of that department.

The herbaceous ſort is alſo raiſed from ſeeds procured from America, ſowing them in April half an inch deep in a warm border; the plants will riſe in a month, which in September or October may be planted out in the borders. Alſo by ſlipping the roots.

CASSINE, Hottentot Cherry, and Cape Phillyrea, formerly *Maurocenia.*

Of this genus are two beautiful evergreen African ſhrubs for the green-houſe, adorned with ſimple leaves, and cluſters of white flowers.

Claſs and order, *Pentandria Trigynia.*

*Characters.*] CALIX, a ſmall, five-parted, permanent cup. COROLLA is divided into five ſuboval obtuſe ſegments. STAMINA, five ſpreading filaments, and ſimple antheræ. PISTILLUM, a conical germen, no ſtyle, but three reflexed ſtigmas. PERICARPIUM, an umbilicated trilocular berry, having three ſeeds.

The ſpecies are,

[1]CASSINE *Maurocenia.*

*Maurocenia, or Hottentot Cherry.*] Caſſine with a woody branching ſtem ſix or eight feet high; ſuboval, thick, entire, rigid leaves; and ſmall cluſters of white flowers at the ſides of the branches, ſucceeded by large, roundiſh, red, cherry-like fruit, ripening here in winter.

[2]CASSINE *Phillyrea.*

*Phillyrea of the Cape of Good-Hope.*] Caſſine with a woody branchy ſtem, five or ſix feet high; oblong, ſawed, ſtiff, oppoſite leaves; and ſmall cluſters of white flowers at the ſides of the branches, ſucceeded by red berries, but ſeldom appear in England.

For the other ſpecies formerly of this genus, *Caſſio-berry Buſh*, and *Yapon*, ſee VIBURNUM and PRINOS.

The flowers ſeparately of both ſorts have the corolla divided into five ſpreading ſegments, and the ſeaſon of flowering is July.

Both of the above ſpecies having ſingularly beautiful leaves, appearing very ornamental all the year, merit places in every green-houſe collection; they muſt be kept in pots of rich light earth, and continued in the open air all ſummer, and the green-houſe in winter, managing them as other woody exotics of that department. See GREEN-HOUSE PLANTS.

*Propagation.*

They are propagated by ſeeds, and by layers of their young branches.

Sow the ſeed in ſpring in pots of light earth plunged in a hot-bed, or the ſtove bark-bed, and when the plants are two or three inches high, prick them in ſeparate pots, placing them alſo in a hot-bed, and afterwards gradually harden them to the full air for the remainder of the ſummer.

By layers, chuſe young ſhoots, lay them in ſpring or autumn, and by autumn following they will be rooted, and fit to be planted in ſeparate pots.

CASTRATIO, Caſtration of Plants.

Caſtrated plants are ſuch which are deprived of the male organs, i. e. the antheræ, either by nature, or by having them cut off, as ſometimes practiſed, to try experiments with reſpect to the doctrine of the ſexes of plants. See SEXUS.

CATANANCHE, *Catananche*, or Candia Lion's-foot.

This genus furniſhes hardy herbaceous ornamental plants, obtaining two feet ſtature, adorned with long jagged leaves, and terminated by compound blue flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, compound flowers, having

having a ſcaly, elegant, permanent, general cup. COROLLA, ſeveral broad, tongue-ſhaped, five-parted, hermaphrodite florets. STAMINA, five filaments, and cylindric pentagonal antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and two revolute ſtigmas. PERICARPIUM, none; oval ſeed, crowned by a downy pappus, lodges in the calix.

There are two ſpecies, a perennial and annual, the former of which only merit culture, which is,

CATANANCHE *Cærulea.*

*Perennial Blue-flowered Catananche.*] Catananche with a fibrey perennial root, crowned by long, narrow, jagged, hairy, proſtrate leaves; upright branchy ſtalks two feet high, garniſhed with ſmall leaves, and all the branches terminated by ſingle heads of blue flowers, having purple bottoms, golden antheræ, and ſilvery cups.

*Variety.*] Perennial Blue Catananche with double flowers.

Theſe are very ornamental flowery perennials, both in their ſingle and double ſtate, continuing in flower from May till September, and ſucceed in the full ground in dry and ſomewhat ſheltered borders, where they will endure many years, and produce flowers and ripe ſeed annually; but being ſomewhat tender, it is proper to keep ſome alſo in pots for ſhelter in winter by way of reſerve.

As to their propagation, the ſingle ſort is propagated by ſeeds ſown half an inch deep, in a bed of light earth in March or April.

Both ſingle and double may alſo be propagated plentifully by ſlipping their roots in autumn, or early in ſpring, but do not ſlip them too ſmall, becauſe the larger the root, the greater number of ſtalks they ſend up for flowering.

CATERPILLARS, deſtructive inſects in our kitchen-gardens, particularly to the cabbages and ſavoys in the end of ſummer.

The ſorts which principally infeſt our gardens, is that yelloviſh green dark-ſpotted Caterpillar, generated from the eggs of the white butterfly, which they are continually depoſiting every where, and in a few days are metamorphoſed to living inſects, ſpreading themſelves ſurpriſingly, and devour the leaves of all the cabbage tribe, firſt attacking the outward leaves, and, if not prevented, continue their depredations to the very heart of the plants.

When our greens, &c. are thus attacked, we have no other remedy than to pick the vermin off repeatedly by hand, which may appear a tedious proceſs, though, in ſmall gardens, it may be ſo far practicable, as greatly to diminiſh their numbers, eſpecially if undertaken before they ſpread conſiderably from their neſt; but in large open grounds the plants often eſcape, when thoſe in more confined places are ſeverely attacked, and more particularly thoſe in the corners of gardens, near walls, buildings, or hedges, which ſhould caution us not to plant any of the cabbage tribe too near ſuch places, nor, if poſſible, where much crowded with trees, for the ſame reaſon.

Beſides the above ſort of Caterpillar, there is a large, dark-coloured, tough-ſkinned ſort, generated in like manner in the heart of the encloſed leaves of the autumn cabbages, ſavoys, &c. and detach themſelves from their lodgement by eating holes through all the leaves.

This Caterpillar alſo burrows in the earth, to the deſtruction of all ſorts of young plants, by eating their ſhanks aſunder; but as it burrows juſt within the ſurface of it, may be readily found, by ſtirring the ground with the fingers about the place.

Our fruit-trees are alſo often attacked in very dry weather by Caterpillars, to the deſtruction of their leaves, &c. nor is there any certain method to deſtroy them, but by picking their neſt off by hand, when practicable, before the vermin begin to ſpread themſelves; or if they have already ſpread, to daſh the trees frequently with water from an engine.

CATESBÆA, Lily-thorn.

There is but one ſpecies, an exotic ſmall-leafed ſhrub of the hot-houſe.

Claſs and order, *Tetrandia Monogynia.*

*Characters.*] CALIX, a monophyllous, four-parted, permanent cup. COROLLA, one funnel-ſhaped, very long, tubular petal, broad and four-parted at top. STAMINA, four filaments, and oblong, erect antheræ. PISTILLUM, a roundiſh germen under the corolla, long ſtyle, and ſimple ſtigma. PERICARPIUM, an oval unilocular berry, containing angular ſeeds.

The ſpecies is,

*Cateſbæa Spinoſa.*] Cateſbæa with a woody, ruſſety, ſpinous ſtem, branching alternately, riſing eight or ten feet high; ſmall roundiſh leaves in cluſters; and very long, pendulent, yellow flowers, ſingly from the ſides of the branches, ſucceeded by oval, fleſhy, ſaffron-coloured berries.

This

This ſhrub muſt be always kept in pots of light ſandy compoſt, and retained conſtantly in the ſtove.

It may be propagated by ſeeds, and by cuttings of its young ſhoots; the ſeeds are procured from abroad, which ſow in pots of light earth, and plunge them in the bark-bed. Cuttings may be planted any time from April till July, in pots plunged in the tan-bed; and if cloſe covered with hand-glaſſes, will facilitate their rooting.

CATKIN, an amentaceous flower, i. e. conſiſts of a great number of chaffy ſcales and flowers, diſperſed along a ſlender thread-like receptacle, hanging downward, and is the male flowers of the trees which produce them, as birch, beech, pine, fir, poplar, walnut, hazel, &c. See AMENTUM.

CAULESCENS *Planta*, from *Caulis* the ſtem, having a ſtem or trunk as in moſt plants, oppoſed to *Acaulis*.

CAULIS, a Stalk or Stem, the firſt and moſt common ſpecies of *Trunk*, expreſſive of that part of a plant or tree which ariſes immediately from the root, produces and ſupports the branches, leaves, flowers, and fruit. See TRUNCUS.

A Stalk, Stem, or Trunk, is either ſimple, ſimple-branching, or compound-branching.

As for example, ſimple Stalks are ſuch as riſe ſingly, and continue undivided from the root to the top; ſimple-branching Stems may be deemed ſuch as either riſe wholly undivided, but ſend out many ſide or lateral branches, or ſuch that proceed ſingly to ſome conſiderable length, and then divide into branches near the top; compound-branching Stems are ſuch that ſoon divide into others, and theſe ſubdivide into many *ramuli* or branches.

As Stems aſſume different directions, ſhapes, and other appearances, the botaniſts diſtinguiſh them accordingly by the following different terms:

*Cauli integri*, entire or ſimple Stalks, and which are either *erecta*, erect, or upright, as in moſt plants; *flexuoſa*, of different directions at each joint; *reclinatus*, reclinating, or bending archways to the ground; *volubilis*, voluble, twining or winding aſcendingly round other plants or any ſupport, either to the left, as in honeyſuckle, hop and black briony; or to the right, as in convolvulus, kidney-bean, &c. *oblique*, growing aſlant; *procumbens*, lying along the ground; *repens*, creeping along the ground, rooting at every joint.

*Cauli Ramoſus*, ſimple-branching Stems, which are alſo either erect, flexuoſe, reclining, voluble, &c. as above, and have different terms according to their modes of branching, as *ramoſus*, branching out laterally; *ramoſiſſimus*, very branchy; *aſcendens*, the branches gradually curving upwards; *diffuſus*, diffuſed, or very ſpreading branches; *brachiata*, large arms, or branches in pairs, each pair ſtanding at right angles with thoſe immediately above and below; *fulcratus*, ſupported by branches deſcending to the earth; *prolifer*, prolific, branching only from the apex or ſummit.

*Caulis Compoſitus*, compound branching Stems, and, according to their modes of branching, are termed *dichotomus*, forked or divided into others, the diviſions by two and two; *ſubdiviſus*, the diviſions ſubdivided into many branches irregularly.

*Articulatus*, articulate, or jointed, compoſed of many joints, having knots at certain diſtances.

*Paraſiticus*, paraſitic, growing out of, and ſupported on other plants or trees, as the miſſetoe.

When Stems are of different figures, they are denominated *Caulis teres*, cylindrical and taper; *anceps*, anticipal, or two-edged; *trigonous*, three-angled; *triqueter*, triquetrous, having three plane ſides; *tetragona*, ſquare, or four-ſided; *pentagona*, five angled; *polygona*, many angled.

When furrowed, ſmooth, rough, &c. they are *Caulis ſulcatus*, deeply furrowed; *ſtriatus*, ſtreaked, or ſuperficially furrowed or fluted; *glaber*, a ſmooth ſurface, oppoſed to *ſcaber*, rough, ſcabby, or full of rigid points or tubercles; *villoſus*, hairy or ſhaggy; *hiſpidus*, hiſpid or briſtly; *aculeus*, prickly; *ſpinoſus*, ſpinous, thorny; *tomentoſa*, tomentoſe, or downy.

Leafleſs and leafy Stalks are termed *Caulis nuda*, naked or leafleſs; *foliatus*, folioſe, or ornamented with leaves, as obtains in moſt plants.

As to duration, Stems are either of one year's duration, *Caulis annua*; of two, *Caulis biennis*; of many years duration, *Caulis perennis*, as obtain in all trees and ſhrubby plants.

CEANOTHUS, New-Jerſey Thea, ſo called from the leaves being there uſed as tea.

This genera retains three ſpecies of the tree and ſhrub kind, one for the ſhrubbery, one for the green-houſe, and one for the ſtove,

ſtove, all garniſhed with ſimple leaves, and numerous ſpikes of quinquepetalous white flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a monophyllous, turbinated, acutely five-parted, permanent cup. COROLLA, five roundiſh ſpreading petals. STAMINA, five ſubulated filaments, and roundiſh antheræ. PISTILLUM, a trigonal germen, cylindric ſemitrifid ſtyle, and obtuſe ſtigma. PERICARPIUM, a dry, trilocular, obtuſe berry, having three oval ſeeds.

The ſpecies are,

[1]CEANOTHUS *Americanus.*

*American Deciduous Ceanothus, or New-Jerſey Thea.*] Ceanothus with a ſhrubby very branchy ſtem about a yard high, ſending out numerous reddiſh flexible branches from the bottom upward, garniſhed with oval, ſerrated, pointed, trinorvous leaves, and all the branches and ſhoots terminated by cluſters of white flowers.

[2]CEANOTHUS *Africanus.*

*African Evergreen Ceanothus, or Alaternoides.*] Ceanothus with a woody rough ſtem, and weak purpliſh branches, riſing eight or ten feet high; ſpear-ſhaped, pointed, ſerrated, ſmooth, ſhining green leaves, and cluſters of ſmall greeniſh flowers from the ſides of the branches.

[3]CEANOTHUS *Aſiaticus.*

*Aſiatic Ceanothus.*] Ceanothus with a ſhrubby branchy ſtem, growing four feet high; oval, pointed, cloſe-ſitting, oppoſite leaves; and greeniſh flowers in ſmall cluſters from the ſides of the branches.

The flowers ſeparately of all the ſorts are compoſed of five ſmall petals appearing in July, which of the firſt ſort is ſometimes ſucceeded by ripe ſeeds in England, but never any of the others.

The firſt ſpecies, *Ceanothus Americanus*, is a moſt elegant little flowering ſhrub, as when it flowers it appears wholly covered with bloom, and therefore is well calculated for the moſt conſpicuous compartments of the ſhrubbery plantations, allowing it a moderately dry ſoil and ſomewhat ſheltered ſituation in the fronts of the clumps.

The ſecond ſort is alſo worthy of a place in the green-houſe collection, for the beauty of its ſhining green leaves, appearing ornamental the year round.

The third ſort is alſo retained in ſome of our ſtoves for variety.

*Propagation.*

The firſt ſort is propagated both by ſeeds and layers.

Sow the ſeed in autumn, or as ſoon as they can be procured, in pots of light compoſt a quarter of an inch deep, placing them in a frame, to have occaſional ſhelter in bad weather, and in ſpring plunge them in a hot-bed to bring up the plants, hardening them gradually to the full air in ſummer, but remove them in autumn, to have occaſional ſhelter until March; then plant them out in ſeparate ſmall pots, or in a nurſery-bed in the full ground, where they can be covered occaſionally again the following winter, for they muſt have protection from ſevere froſt the two or three firſt years of their growth.

To propagate them by layers, chuſe ſome of the youngeſt branches in autumn, and lay them in the uſual way, which will be rooted in a twelvemonth, and in ſpring after tranſplant them; or, if you likewiſe lay ſome of the firſt young ſhoots in June or July, you will have the greater chance of ſucceſs.

The ſecond ſort is propagated expeditiouſly by laying down the young ſhoots, either in their own pots, or others placed for the purpoſe; it is likewiſe encreaſed by young cuttings, planted in the ſpring in pots, plunging them in the bark-bed, or any other hot-bed, about two months.

The third ſpecies may be raiſed from ſeeds in pots of light earth, plunging them in the bark-bed, &c. likewiſe by laying the young ſhoots, plunging the pots as juſt directed.

CELASTRUS, Staff-tree.

In this genus are ſome curious evergreen and deciduous ſhrubs for the ſhrubbery and green-houſe of moderate growth, ornamented with ſimple leaves, and bunches of whitiſh five-petalled flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a monophyllous unequally five-parted cup. COROLLA, five oval ſpreading-equal petals. STAMINA, five filaments, and very ſmall antheræ. PISTILLUM, a ſmall germen immerſed in a very large receptacle, marked with ten channels; a ſhort ſtyle, and blunt trifid ſtigma. PERICARPIUM, a trigonal, trivalvate, trilocular, coloured capſule, and oval ſeeds.

The ſpecies are as follow: the two firſt are hardy ſhrubs.

[1]CELASTRUS *Bullatus.*

*Studded-fruited Celaſtrus, or Virginia Evergreen Staff-tree.*] Celaſtrus with ſeveral upright, ſhrubby, branching ſtems, four or five feet high; oval, entire, alternate leaves; and at the ends of the branches ſpikes of white flowers,

flowers, ſucceeded by three-cornered, ſcarlet, bullated capſules, which rarely attain perfection in England.

[2]CELASTRUS *Scandens.*

*Climbing Staff-tree, or Baſtard Euonymus.*] Celaſtrus with climbing ſhrubby ſtalks, twining upon ſupport, or about each other, twelve or fifteen feet high; oblong ſlightly-ſawed leaves placed alternate; and greeniſh flowers in bunches at the ſides of the branches, ſucceeded by three-cornered red capſules, ripening here in autumn.

The three following are green-houſe ſhrubs.

[3]CELASTRUS *Pyracanthus.*

*Pyracantha-leaved Evergreen Celaſtrus, or Æthiopian Box-thorn.*] Celaſtrus with ſhrubby, upright, irregular ſtems, and taper brown branches; grows a yard or more high, garniſhed with ſpear-ſhaped, pointed, ſhining green leaves, and cymoſe bunches of whitiſh-green flowers at the ſides of the branches, ſucceeded by oval, trigonous, beautiful red capſules.

[4]CELASTRUS *Buxifolia.*

*Box-leaved Evergreen Celaſtrus* ] Celaſtrus with ſlender, ligneous, jointed, aſh coloured, ſpinous ſtems, and angular ſpinous branches riſing eight or ten feet high; ſmall, longiſh, obtuſe leaves, placed in cluſters irregularly; and cymoſe bunches of whitiſh flowers.

[5]CELALTRUS *Myrtifolius.*

*Myrtle-leaved Celaſtrus.*] Celaſtrus with woody, upright, unarmed ſtems and branches, growing twelve or fifteen feet high; oval, ſerrated, ſtrong, green leaves; and long bunches of whitiſh flowers at the ſides of the branches.

The flowers of all theſe ſpecies are compoſed ſeparately of five oval ſpreading petals, and appear principally in June and July.

The firſt two ſpecies are proper for the embelliſhment of the ſhrubbery compartments, the firſt of which, *Celaſtrus Bullatus*, ſhould have a dry and ſomewhat ſheltered ſituation in the fronts of clumps, and they will retain their leaves moſt of the year; but the ſecond ſort is exceeding hardy, and will proſper any where among trees and tall ſhrubs, on the edge of plantations, or in woods and wilderneſs-works, where they will mount themſelves conſiderably, and their ripe fruit will make an elegant appearance in autumn.

The laſt three ſorts are tender, ſo muſt be always kept in pots to have ſhelter in winter.

They are elegant furniture for the green-houſe collection. Let them be planted ſeparately in pots of rich light mould, and manage them as myrtle and other ſhrubby exotics of the like temperature. See GREEN-HOUSE PLANTS.

*Propagation of all the Sorts.*

The firſt two ſorts are raiſed from ſeeds in beds of light earth; alſo by layers of their young branches.

Sow the ſeeds in autumn, or early in ſpring, an inch deep, in a bed of light fine earth, obſerving, that as the plants rarely riſe till the ſecond ſpring, the beds all the intermediate time muſt be kept clean from weeds; and when the plants riſe, continue the care of weeding and occaſional waterings in ſummer; and after having two years growth in the ſeed-bed, plant them out in nurſery-beds.

Cuttings may alſo be ſtruck by aid of artificial heat.

By layers it is performed in autumn, making choice of the young wood, giving each layer a ſlit at a joint, and they will be rooted, and fit to tranſplant in nurſery-rows.

The three green-houſe kinds may alſo be propagated by ſeeds, layers, and cuttings. Sow the ſeed in pots an inch deep, as ſoon as they can be procured in autumn or ſpring, and place them in a frame, to have ſhelter in bad weather, and occaſional ſhade in ſummer; and when the plants are a year old plant them in ſeparate pots.

Cuttings planted in pots in ſpring, and plunged in a hot-bed a month or two, they will readily emit roots.

Layers of the young branches in ſpring will be rooted by autumn.

CELOSIA *Amaranth*, or Cock's-Comb.

This genus furniſhes beautiful ornamental annuals, riſing from one to five or ſix feet high, garniſhed with large oval or ſpear-ſhaped leaves, and crowned by moſt elegant large heads of flowers, in ſome reſembling the figure of a cock's comb.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a coloured, ſmall, three-leaved, permanent cup to each floret. COROLLA, five ſpear-ſhaped, erect, ſtiff, permanent petals, ſhaped like the calix, and a ſmall nectarium attached to the border of the germen. STAMINA, five filaments, and turning antheræ PISTILLUM, a globoſe germen, erect ſtyle, and ſingle ſtigma. PERICARPIUM, a ſmall globular capſule of one cell, and very ſmall roundiſh ſeeds.

There are ſeveral diſtinct ſpecies, all very beautiful garden-flowers; but the ſort called

Cock's-Comb is the moſt grand and elegant of all, and which is the ſort moſt commonly cultivated in our gardens, and the firſt ſpecies here deſcribed, which admits of ſeveral varieties in reſpect to ſtature, and in the colour of the flowers.

The ſpecies are,

[1]CELOSIA *Criſtata.*

*Creſted Flowered Amaranth, or Cock's-Comb.*] Celoſia with an upright, ſingle, ſtiff ſtalk, from one to five or ſix feet high, ornamented from bottom to top with large, oval-ſpear-ſhaped leaves, on angular foot-ſtalks, and the main ſtalk crowned by a large, creſted, flowery head, compoſed of numerous ſmall florets.

*Varieties of this are*] Dwarf Cock's-Comb, from ſix inches to a foot and half high, with large purple heads of flowers—with red heads ——with ſcarlet heads—and with yellowiſh heads.——Giant Cock's-Comb, from a yard to five or ſix feet high, with very large purple heads——with red heads—with ſcarlet heads—with yellowiſh heads——with white heads——and with variegated heads.——Branching Cock's-Comb, dividing into ſeveral branches, each terminated by ſmall heads, of which are purple, red, buff-colour, &c.

[2]CELOSIA *Margaritacea.*

*Pearly-coloured Spiked Celoſia.*] Celoſia with an upright branchy ſtalk two feet high; ſpear-ſhaped, pointed, pale leaves; and the main ſtalk and every branch terminated by ſmall, oblong, erect, pearly-coloured heads, forming ſpikes the ſize of a finger.

*Varieties.*] Pearly Celoſia with oblong ſpikes of equal thickneſs—with pyramidal ſpikes—with entire white ſpikes—with white and red ſpikes.

[3]CELOSIA *Coccinea.*

*Indian Scarlet Spiked Celoſia.*] Celoſia with an upright, large, round, furrowed ſtalk, a yard or more high; oval gathering leaves; and the ſtalks terminated by ſeveral ſmall bright ſcarlet heads, forming ſpikes.

*Varieties.*] Indian Scarlet Celoſia with creſted ſpikes—with incurved creſted ſpikes—and with plumed ſpikes.

[4]CELOSIA *Lanata.*

*Downy Cluſtered-ſpiked Celoſia.*] Celoſia with an upright, downy, white ſtalk, two feet high; lanceolate, obtuſe, very downy leaves; and the ſtalk and branches terminated by cluſtered ſpikes of flowers, having woolly ſtamina.

[5]CELOSIA *Caſtrenſis.*

*Dwarf Creſted Spiked Celoſia.*] Celoſia with an upright very branchy ſtalk a foot and half high; lanceolate acutely-pointed leaves; and all the branches terminated by creſted ſpikes of flowers of ſeveral varieties.

The flowers of all theſe ſpecies, though ſeparately very ſmall, being exceeding numerous, and collected into large compact creſted heads, or in oblong ſpikes, appearing as one large flower, are extremely conſpicuous and elegant, and exhibit a grand appearance in a garden from July to October, particularly the firſt ſpecies, Cock's-Comb and varieties, which produce their flowers in very large plumes or creſted heads, generally but one plume crowning each plant, in ſize from four or five to fifteen inches longways over the crown, and from two to five or ſix broad, and of proportionable depth.

Of the firſt ſpecies, *Celoſia Criſtata*, are two principal varieties, the Dwarf and Giant Cock's-Comb; the former of which, though dwarfiſh, is of very robuſt growth, leaved to the bottom, and crowned by elegant heads, and is eſteemed a curioſity; but the Giant ſorts make the grandeſt ſhew, as, with due culture, they attain at leaſt a yard, but frequently five or ſix feet ſtature, decorated from the very bottom with elegant large foliage, and ſurmounted by wonderful large fine heads: they however require great attention to bring them to real perfection, needing the aid of three or four different hot-beds, and different-ſized deep frames, to draw them up tall; but the dwarf ſorts may be raiſed in tolerable perfection by the aſſiſtance of two hot-beds and common frames, and are therefore the propereſt ſort for gardens that are not well furniſhed with hot dung and garden-frames.

The principal property of a fine Cock's-Comb is, a perfectly upright ſtrait ſtem free from ſide-branches, well furniſhed all the way with leaves; and the plume of flowers large, erect, cloſe, and regular, without any ſide-ſhoots or ſmaller heads.

The other four ſpecies of this genus, though not ſo generally known and eſteemed as the Cock's-Comb kind, however, are very ſhowey plants, and form an elegant variety among the Combs and other curious annuals, and one method of culture brings them all to perfection.

All the five ſpecies are herbaceous, and of the annual tribe, exotics of moſt delicate temperature, being natives of the hot parts of Aſia and America, and, in their culture here, require

require to be raiſed and forwarded in at leaſt two or three different hot-beds from March till June or July; that is, raiſing them from ſeed in one in March, pricking them out into another in April, and to have them very fine, tranſplant them into a third in May, to remain until the end of June or beginning of July, when they will have attained nearly their full ſtature, their heads tolerable perfection, and the weather will be then ſettled and warm, and ſhould be placed abroad, where their heads will continue their full luſtre till October, at which time they ripen ſeeds, then gradually decay, and November cold puts a total period to their exiſtence; ſo that a freſh ſupply muſt be annually raiſed from ſeed in ſpring.

All the ſorts are generally planted in pots, particularly the Cock's-Combs, to arrange in fore courts, or to move to any place where a grand ſhew is at any time occaſionally wanted; but, if required, ſome may alſo be raiſed for the borders, without employing ſo much nicety in their culture as thoſe you intend to pot for the grand ſhew; but even in this caſe two different hot beds is requiſite, raiſing them in one, and pricking them out into another, to remain till June.

*Propagation, General Culture, &c.*

As before obſerved, all the ſorts are raiſed from ſeeds annually in hot-beds under frames and glaſſes, and the proper time to ſow them is the beginning or middle of March.

Obſerve alſo, as already hinted, that to have theſe plants as fine as poſſible, three different hot-beds are neceſſary in their culture; that is, a ſmall one in March, wherein to ſow the ſeed and raiſe the plants an inch or two high; a ſecond in April of larger dimenſions, in which to prick the plants three or four inches diſtance; and a third in May for a large frame, to receive them tranſplanted into pots, to remain until the end of June or beginning of July to grow to full ſize; all of which hot beds muſt be covered with frames and glaſſes, and have five or ſix inches depth of fine rich light earth for the reception of the ſeed and plants; and in the ſecond and third hot-bed the frames muſt be occaſionally raiſed or augmented in depth according as the plants ſhall riſe in height, which is to be particularly attended to in the Giant Cock's-Comb.

Therefore, whoever intends the culture of theſe plants, ought to be well furniſhed with hot dung, and different-ſized frames and glaſs lights. See ANNUAL PLANTS.

The firſt hot-bed in March, for the reception of the ſeed and raiſing the plants an inch or two high, need not be larger than for a one-light frame, which will raiſe a due quantity of theſe and other curious annuals for furniſhing any private garden, obſerving to make the bed two feet and half depth of dung, and directly put on the frame and glaſs, and in four or five days, when the rank ſteam and firſt violent heat abates, put on the mould, which muſt be light, rich, and dry, laying it four or five inches thick; then either ſow the ſeed on the ſurface, and cover it half a quarter of an inch deep; or draw very ſhallow drills with the finger, ſow it therein, covering it the ſame depth; this done, immediately put on the glaſs again, and tilt it a little in the middle of mild days for the evaporation of the ſteam, &c. the plants will appear in a few days, when air muſt be judiciouſly admitted, by tilting the upper-end of the light an inch or two high every mild calm day; and when the earth appears dry, give very light ſprinklings of water in ſunny weather, keep the glaſs cloſe on nights, and continue to cover it with a mat; and in this manner continue the care of the plants till large enough to be pricked into another hot-bed, which will be in about three weeks.

About the middle of April therefore, or a little before or after, when the plants are an inch or two high in the ſeed-bed, another hot-bed for a two or three-light frame muſt be got ready to prick them in, as juſt hinted; make this bed alſo about two feet ſix inches, or a yard thick of dung, place the frame and glaſſes thereon, and when the burning quality of the bed ſubſides, mould it five or ſix inches deep, and next day, when the bed has imparted a due warmth to the mould, raiſe the plants with care from the ſeed-bed, and prick them in this, four or five inches diſtance; give a very light ſprinkling of water, and directly put on the lights, and give occaſional ſhade in ſunny days till the plants are rooted, obſerving to admit freſh air every fine day, as above; give alſo occaſional very light waterings every two or three days, and defend the glaſſes on nights with mats, as before adviſed; and, according as the plants advance in height, raiſe the frame a little in proportion: here they may grow a month or five weeks, by which time they will meet, when they muſt be moved into a third and final hot bed, pre-

viouſly planting ſome of the beſt ſingly in pots, as hereafter directed.

Their ſecond removal will be neceſſary towards the middle of May, or when the plants in the above ſecond bed are ſo much advanced as to preſs againſt each other, when a third and final hot-bed ſhould be made for one or more of the largeſt frames, to receive the plants in pots, obſerving, if you raiſe principally the Dwarf ſorts, one of the deepeſt common garden-frames may be ſufficient, with a little occaſional raiſing at bottom; but for the Giant ſorts, which ought to be drawn up at leaſt three or four feet high, a deep drawing-frame, or rather a multiplying drawing-frame of two or three diviſions, that the depth can be occaſionally augmented, is neceſſary; or, in default thereof, any common frame, raiſed occaſionally upon four poſts: and for the more commodiouſly uſing theſe drawing-frames for the tall Cock's-Combs, the hot-bed ſhould be ſunk eighteen inches in the ground, by making it in a trench that depth; but where there is a glaſs-caſe, calculated on purpoſe for drawing curious annuals, this third hot-bed for the tall ſorts ſhould be made in that department. See ANNUAL PLANTS. Let the hot-bed in either method be two feet ſix inches at leaſt depth of dung, which, when of due temperature, earth five or ſix inches thick, and next day proceed to put in the plants, obſerving, that ſuch as you intend for pots, both of the Dwarf and Giant kinds, ſhould now be potted, and the pots called twenty-fours are the proper ſize, one plant to each pot, being careful to take up the plants out of their preſent bed with a garden trowel, ſo as to preſerve a ball of earth to the roots of each plant; place one in each pot with the ball entire, and fill up round the ball with more rich earth; give ſome water, and directly plunge the pots to their rims in the earth of the bed, placing them cloſe together every way; at the ſame time let all the cavities between be cloſely filled with mould, that the ſteam may no where ariſe immediately from the dung, which would attack and deſtroy the leaves of the plants. The plants being thus all potted and plunged, put the glaſſes immediately on the frame, and ſhut them down cloſe to draw up the heat, but raiſing them a little the next, and every ſucceeding day, that the ſteam may paſs off: be now careful to ſhade the glaſſes in the middle of ſunny days for the greateſt part of the firſt week till the plants have taken good root; freſh air during their reſidence here muſt alſo be daily admitted, by tilting one or both ends of the lights more or leſs in fine weather, in proportion to the advanced growth of the plants; water muſt likewiſe be afforded them twice a week, or oftener, when the weather is very hot and ſunny, and every night continue to protect them from cold by ſhutting the glaſſes cloſe, and cover them with mats; attention muſt alſo be had to maintain a conſtant moderate temperature of heat in the bed, by occaſional moderate linings of hot dung to its ſides, and by obſerving this, together with a proportionable ſupply of freſh air and moiſture, the plants will now make great progreſs, and their heads will encreaſe conſiderably in magnitude.

Likewiſe obſerve, that according as the plants of the large ſorts advance in ſtature, to afford them due ſcope to ſhoot, by augmenting the depth of the frame by ſome of the methods above obſerved, and as explained in the article ANNUAL PLANTS.

With regard to the Dwarf ſorts, if deſigned to have them in their natural dwarfiſh growth, they muſt not be drawn in deep frames, &c. like the others; ſo that the frame containing them need be only a little raiſed by degrees at bottom, continuing the glaſſes always near the heads of the plants, to prevent their drawing up too much to ſtem, which, as it is not their natural growth, if they were much drawn, it would render them weak, and their heads would be but of inconſiderable ſize.

Towards the latter end of June the plants in general will be well advanced in growth, and the weather well ſettled and warm, when it is proper to begin to harden them gradually to the full air, by raiſing the glaſſes every day more and more at each end on props, and by degrees take them wholly off, and in the firſt week in July remove the plants in their pots fully abroad, where they are finally to remain; at the ſame time let each of the tall ſorts be ſupported with a ſtrait, firm, handſome ſtake, tying the ſtem of the plant thereto in three different places.

When placed in the open air, by no means neglect watering them in dry weather, which, when very hot and ſunny, the waterings ſhould be repeated every day; for, if not duly ſupplied with this article, the leaves will ſhrink, and the heads of the flowers become irregular.

When deſigned to raiſe any of theſe plants for the borders, ſow the ſeed, as before, in the

the middle or latter end of March, and towards the end of April or beginning of May prick the plants in a freſh hot-bed ſix or eight inches diſtance, managing them as already directed until the middle of June; then tranſplant them with balls of earth to their roots in the borders, &c. but theſe will not be near ſo fine as thoſe forwarded by the methods before directed.

All the ſorts perfect their ſeeds in September and October, when great care is neceſſary to ſave it only from the moſt perfect heads; and be particularly careful to preſerve the Dwarf and Giant ſorts of the Cock's-Comb kinds ſeparate; obſerving likewiſe, if very wet cold weather prevail at this time, the plants ſhould be placed in a deep or raiſed frame, for the heads to have occaſional ſhelter of the glaſſes from exceſſive rains.

CELTIS, the Lote, or Nettle-tree.

There are three ſpecies, all of them hardy deciduous trees, with very branchy diffuſed heads, garniſhed with ſimple, oblong, deeply ſawed, alternate leaves, ſomewhat reſembling thoſe of the common ſtinging-nettle; and all three ſpecies are proper for ornamental plantations, and two of them alſo as foreſt-trees.

Claſs and order, *Polygamia Monoecia.*

*Characters.*] CALIX, hermaphrodite and male florets, having monophyllous, five-parted cups COROLLA, no petals. STAMINA, five ſhort filaments, and quadrangular four-furrowed antheræ. PISTILLUM, an oval germen, two reflexed ſtyles, and ſingle ſtigmas. PERICARPIUM, a roundiſh unilocular berry, containing a ſmall roundiſh nut.

The ſpecies are,

[1]CELTIS *Auſtralis.*

*South-European Black-fruited Nettle-tree.*] Celtis with an upright large ſtem and very branchy head, riſing forty or fifty feet high, garniſhed with large, ſpear-ſhaped, pointed, deeply-ſerrated leaves, and greeniſh flowers from the ſides of the branches in May, ſucceeded by round black fruit the ſize of black-berries.

[2]CELTIS *Occidentalis.*

*Occidental, or American Purple-fruited Nettle-tree.*] Celtis with an upright large ſtem, and very branchy ſpreading head, growing forty or fifty feet high; large, oval, ſharp-pointed, deeply-ſawed, oblique leaves; and greeniſh flowers from the ſides of the branches in May, ſucceeded by purple fruit the ſize of large peas.

[3]CELTIS *Orientalis.*

*Oriental, or Eaſtern Yellow-fruited Nettle-tree.*] Celtis with an upright ſtem, dividing into many ſpreading greeniſh branches ten or twelve feet high; ſmall, oval, heart-ſhaped, ſerrated, oblique leaves; and yelloviſh flowers from the ſides of the branches in ſpring, ſucceeded by large, oval, yellow fruit.

*Varieties.*] Of each ſort there are varieties with bloatched leaves.

The flowers of all theſe trees are hermaphrodites and males on the ſame plant; but thoſe of both ſex being devoid of petals, make no ornamental appearance, and the hermaphrodites only ſucceed to fruit, which, in favourable autumns, ripens tolerably well in England.

All the three ſpecies are deciduous, and of temperature hardy enough to proſper here in any expoſure and ſoil in common with other hardy trees and ſhrubs.

For purpoſes in gardening, they are well calculated for all ornamental plantations, being finely clothed with leaves of a delightful green, which continue their verdure in a ſingular manner to the very laſt, not like moſt other trees of the deciduous race, whoſe leaves diſcover their approaching decay by their gradual change of colour; but theſe exhibit themſelves a beautiful green till November, and even till their fall, about the middle or end of that month; ſo that they are peculiarly well-adapted for plantations, on the boundaries of ſpacious lawns, grand wilderneſs-works, and for the moſt conſpicuous parts of parks, either placed in clumps, or as ſingle objects.

The firſt and ſecond ſorts may alſo be employed as foreſt-trees in any œconomical plantation; for they are of free growth, and their wood being tough and pliable, is valuable for various uſes.

*Propagation.*

The propagation of all the ſorts is effected by ſeeds, either of Engliſh or foreign growth, which may be had of the ſeedſmen, and which grow freely in the full ground.

The bloached-leaved kinds, however, can only be continued by layers, cuttings, or by grafting, &c.

The ſeeds of the others may be ſown in autumn or ſpring; but by ſowing in autumn ſoon after the ſeeds are ripe, they commonly riſe freely the following ſpring; and the ſpring-ſown ſeeds often riſe ſtraggling, and ſometimes remain a whole year before they germinate: let the ſeeds, however, be ſown

as

as ſoon as they can be procured, either in pots, boxes, or in a warm rich border, covering them half an inch deep. When the plants appear, if cold nights prevail, afford them occaſional ſhelter of mats; and in dry hot weather, while the plants are very ſmall, ſhade in the the middle of parching ſunny days will be ſerviceable: likewiſe encourage them during ſummer by frequent waterings. In autumn and winter protect them from froſt by occaſional coverings, as above; and in the end of March, or in April following, prick them out from the ſeed-bed into another in a ſheltered ſituation, placing the plants in rows a foot aſunder; after this they require no farther care than occaſional weeding, and in two or three years they will be ready for the ſhrubbery or other plantations.

If you at any time ſow theſe ſeeds in ſpring, let it be in large pots, or in boxes, &c. and if the plants do not appear, remove them to the ſhade in ſummer, and ſhelter of a warm wall or hedge in winter, to ſtand till ſpring; at which time, if you plunge them in a hot-bed, it will bring up the plants quickly, and greatly forward them: the ſame may be practiſed to ſuch as are ſown in pots in autumn.

CENTAUREA, Centaury, Cyanus, Blue-Bottle, &c.

This genus is very extenſive in herbaceous annuals, biennials, and perennials, to the amount of ſixty ſpecies, moſtly of upright growth, from one to five or ſix feet ſtature, dividing into branches, crowned by ſcaly heads of compound flowers.

A few of them are ornamental plants, and ſome proper for medicine; but far the greater part are plants of little or no merit.

Claſs and order, *Syngeneſia Polygamia Fruſtanea.*

*Characters.*] CALIX, compound radiated flower, having a roundiſh ſcaly empalement. COROLLA, the diſc compoſed of many hermaphrodite fruitful florets, tubular below, ſwelled and five-parted at top; and in the radius, compoſed of neuter or barren florets, tubular, and gradually enlarging, and unequally divided, above. STAMINA, five ſhort hairy filaments, and cylindric antheræ. PISTILLUM, a ſmall germen, ſlender ſtyle, and blunt ſtigma. PERICARPIUM, none; the ſeeds lodge in the calix.

The ſpecies that merit culture are as follow: the firſt five are very hardy perennials, perennial in root, but annual in ſtalk, &c.

[1]CENTAUREA *Centaurium.*

*Greater Purple Centaury.*] Centaury with a ſtrong perennial root, crowned by many winged very long leaves, ſpreading flat every way; upright branching ſtalks five or ſix feet high; a ſmall winged leaf at each joint, and all the branches terminated by a ſingle head of purple flowers in ſmooth cups.

[2]CENTAUREA *Glaſtifolia.*

*Great Woad-leafed Yellow Centaury.*] Centaury with a penetrating perennial root, crowned by many long, entire, erect leaves; ſeveral upright ſtalks four or five feet high, having a ſingle decurrent leaf at each joint; and all the ſtalks terminated by a ſingle head of yellow flowers in ſcaly ſilvery cups.

[3]CENTAUREA *Stœbe.*

*Hoary Stœbe of Auſtria.*] Centaury with a perennial root, crowned by many pinnatifid hoary leaves of many narrow entire ſegments; upright branchy ſtalks a yard high, a winged leaf at each joint, and each branch topped by a head of purple flowers in oblong ciliated cups.

[4]CENTAUREA *Orientalis.*

*Oriental Centaury, or Great Yellow Knapweed of Siberia*] Centaury with perennial roots, crowned by pinnatifid very long leaves of many lobes; upright very branchy ſtalks five feet high, garniſhed with ſmall pinnatifid leaves; and all the branches terminated each by a large ſingle head of yellow flowers in ciliated cups.

[5]CENTAUREA *Montana.*

*Mountain Perennial Blue-Bottle, or Blue Bachelor's-Button.*] Centaury with very creeping perennial roots; many upright ſingle ſtalks a foot and half high, garniſhed with ſpear-ſhaped, hoary, decurrent leaves; and all the ſtalks crowned by oblong heads of blue flowers in ſerrated cups.

*Varieties.*] Broad-leaved Perennial Blue-Bottle—Narrow-leaved Perennial Blue-Bottle—Dwarf Perennial Blue-Bottle.

The two following are perennial in root, ſtalks, and leaves; are rather impatient of ſevere froſt, but will live in the full air in a dry ſheltered ſituation.

[6]CENTAUREA *Raguſina.*

*Raguſian Silvery Knapweed, or Cinara-leafed Centaury.*] Centaury with a perennial root, upright branchy perennial ſtalks a yard high; large, pinnatifid, white, downy leaves, of many oval obtuſe lobes, the exterior ones the largeſt; and all the branches adorned with heads of bright yellow flowers, in June, in fine hairy cups.

[7]CEN-

7 CENTAUREA *Cineraria.*

*White Mountain Napweed of Italia.*] Centaury with perennial roots; upright, branchy, perennial ſtalks, near a yard high; pinnatifid, very white, downy leaves, of many narrow acute ſegments; and every branch crowned by a head of purple flowers in ciliated cups.

The three following are hardy annuals.

8 CENTAUREA *Cyanus.*

*Cyanus, or Annual Blue-Bottle, or Bottles of all Colours.*] Centaury with annual roots; upright branchy ſtalks two or three feet high; narrow leaves, the lower ones indented, thoſe above very narrow and entire; and the ſtalks and branches terminated by ſcaly heads of flowers, of various colours in the different varieties.

*Varieties.*] Common Blue-Bottle with blue flowers—blue and white flowers——purple flowers—purple and white flowers—fleſh-coloured flowers—fleſh-coloured and white flowers——violet-coloured flowers——violet and white flowers—red flowers—double blue flowers——double purple flowers——double purple and white flowers.

9 CENTAUREA *Moſchata.*

*Muſk-ſcented Oriental Cyanus, or Sweet Sultan.*] Centaury with annual roots; an upright, channelled, branchy ſtalk, a yard high, garniſhed with jagged, ſmooth, cloſe-ſitting leaves; and from the ſides of the branches many long, erect, naked foot-ſtalks, each ſupporting a ſingle head of odoriferous flowers in round, ſcaly, ſmooth cups.

*Varieties.*] Sweet Sultan with purple flowers—with white flowers—with fleſh coloured flowers—with purple fiſtulous flowers—white fiſtulous flowers—with fringed flowers—*Amberboi*, or Yellow Fiſtular Sultan, having ſawed leaves, and bright yellow fiſtular flowers.

10 CENTAUREA *Benedicta.*

*Carduus Benedictus, or Bleſſed Thiſtle.*] Centaury with annual roots; very branching, hairy, reddiſh ſtalks, near two feet high; long, deeply-ſinuated, hairy, decurrent leaves, having the ſegments ending in ſpines; and the ends of the branches crowned by heads of pale yellow flowers in oval, ſcaly, doubly-ſpinous cups

The flowers of all the ſpecies and reſpective varieties are compound and radiated; that is, each flower is of many florets, in the centre and circumference, contained in one ſcaly general cup. See the *Characters.*

They all flower in June, July, and Auguſt, and moſtly ripen ſeeds in England.

All the ſpecies, except the *Carduus Benedictus*, may be employed as ornamental plants in the common ground, where, though we have many plants of more ſhowey appearance, they will effect an agreeable variety.

As to the perennial ſpecies, the firſt five are proper furniture for the compartments of extenſive gardens, where many large plants of free growth and eaſy culture are required, as they will ſucceed in any common expoſure and ſoil where moiſture is not too copious. The ſixth and ſeventh ſpecies are rather tender, ſo ſhould have a perfectly dry ſoil and ſheltered ſituation, otherwiſe will be in danger of ſuffering in ſevere winters. A plant or two of each ſort may alſo be potted to move to occaſional ſhelter from froſt; for, as they retain their white hoary leaves all the year, they make a pretty variety in a garden.

The annual ſorts, *Centaurea Cyanus*, and *Centaurea Moſchata*, are pretty ornaments for the borders of the pleaſure-ground. The firſt of theſe annuals grows naturally in our cornfields, particularly the common blue ſort, but which, and its numerous varieties, have alſo been long inhabitants of gardens, and are all very hardy, riſing from ſeed freely in the open borders; but the other ſort and varieties are natives of the Eaſt, from whence they have been long introduced into the European gardens for the beauty of their flowers, which continue in ſucceſſion from June till October: the plants being ſomewhat tender, require to be raiſed in a hot-bed in ſpring, and planted out in May, though they will riſe in a warm border in April; but theſe will not flower ſo ſoon as thoſe raiſed in a hot-bed: the *Amberboi*, or Yellow Sultan, in particular, requires that aſſiſtance.

The tenth ſort, *Centaurea Benedicta*, or *Carduus*, is conſidered principally as a medical herb, and its emetic property is well known.

*Propagation of all the Sorts.*

All the perennial ſorts are propagated by ſeeds and parting their roots, and the ſixth and ſeventh ſorts alſo by ſlips or cuttings of their branches.

Sow the ſeeds of all the ſorts in a bed or border of common earth in March; keep the plants clean from weeds, thin them where too thick, and in autumn following tranſplant them into the places of their final deſtination.

By

By ſlipping the roots; it may be done any time in open weather from October till March

Cuttings or ſlips of the young ſide-branches of the ſixth and ſeventh ſorts, planted in a ſhady border in May, June, or July, will readily grow.

The annual ſorts are raiſed from ſeed annually.

The *Centaurea Cyanus*, or Blue Bottle, and varieties, may be ſown in the borders in patches, in the places where they are to flower, ſowing ſeveral ſeeds in each patch half an inch deep.

The *Centaurea Moſchata*, or Sweet Sultans, will alſo riſe from ſeed in the common ground, ſowing it in March or April, either in the places where they are to flower, as directed for the Blue-Bottles, or in a warm border under hand or bell-glaſſes, or without, and plant them out in May or June into different parts of the borders; but if the ſeeds are ſown in a hot-bed at the above time, it will forward the plants for tranſplanting in May, and they will flower near a month ſooner than the others. The Yellow Sultan in particular, being rather a little tender, ſhould be principally raiſed in a hot-bed, and if pricked on another in April or beginning of May, it will forward them greatly, and about the end of that month, or beginning of June, tranſplant them finally with balls to their roots, placing ſome in pots, and ſome in the borders.

If the ſeeds of the common Sultans are ſown in autumn, ſoon after they ripen, in a warm border, the plants will come up, ſtand the winter, and flower the ſummer following ſooner by a month than the ſpring-ſown plants.

The *Carduus* may be ſown in autumn or ſpring in the common ground; by ſowing in autumn the plants ſtand the winter, grow ſtronger, and will be fit for uſe ſooner than the ſpring plants. The ſeed may either be ſown in ſhallow drills a foot aſunder, and when the plants come up thin them to eight inches diſtance; or ſow the ſeed promiſcuouſly on the ſurface, and rake it in, thinning the plants as above; or they may be ſown thick, and afterwards tranſplanted the above diſtance: they will ſhoot up to ſtalk in May or June, and flower in July, at which period they are in perfection to cut for uſe, cutting it cloſe to the bottom; and after drying in the ſhade a few days, bunch it for uſe.

CEPHALANTHUS, Button-tree, ſo called from its mode of flowering.

There is but one ſpecies, a hardy, deciduous, flowering ſhrub of American growth, garniſhed with ſimple, oblong leaves, and ſmall globular heads of flowers, and is very ornamental for the ſhrubbery.

Claſs and order, *Tetrandia Monogynia.*

*Characters.*] CALIX, aggregate flower, each floret having a monophylious, funnel-ſhaped, quadrifid cup. COROLLA, many monopetalous, infundibuliforme, acute florets, collected into a round head. STAMINA, four ſhort filaments inſerted into the petal, and globoſe antheræ PISTILLUM, a germen under each floret, ſhort ſtyle, and globular ſtigma. PERICARPIUM, none. SEMINA, pyramidal ſolitary ſeeds, placed on a globoſe hairy receptacle.

The ſpecies is,

CEPHALANTHUS *Occidentalis.*

*Occidental Cephalanthus, or Button-tree.*] Cephalanthus with a branchy ſtem ſix or ſeven feet high, branching in pairs; oblong leaves by pairs and threes, having a ſtrong longitudinal nerve, and ſmall ones tranſverſely; and all the branches terminated by aggregate yellowiſh flowers in globular heads the ſize of gooſeberries, each aggregate compoſed of many funnel-ſhaped florets affixed to an axis in the middle.

It flowers here in July, but rarely ripens ſeeds in England.

This ſhrub deſerves a place in every collection, and proſpers in any common ſoil; but delights moſt in ſomewhat moiſt ground.

The propagation of this ſhrub is by ſeed in the full ground, or in pots or boxes, to move to occaſional ſhade or ſhelter; likewiſe by layers and cuttings.

The ſeeds are obtained from America, and may be had of the ſeedſmen, which ſhould be ſown as ſoon as it arrives, near half an inch deep, and probably the plants will riſe the firſt ſpring, though, if ſown late, they ſometimes do not appear till ſpring following; when this is the caſe, keep the earth free from weeds, giving occaſional ſhade in very hot weather, and ſome protection from ſevere froſt, and in ſpring after the plants will riſe in great plenty: theſe the firſt ſummer ſhould be frequently watered in dry weather, and in the autumn, or autumn twelvemonth after, according to their ſtrength, tranſplant them in nurſery rows two feet diſtance, and half that diſtance in the lines, and in two or three years more they will be fit for the ſhrubbery.

By

By layers and cuttings; the young wood, if layed in autumn, will be rooted and fit to tranſplant by that time twelvemonth; and cuttings of the young ſhoots, planted at the ſame time in a moiſt ſhady border, will grow.

CERASTIUM, Mouſe-ear Chickweed.

It conſiſts of ſeveral low herbaceous plants, moſtly trailers, garniſhed with ſmall ſimple leaves, and quinquepetalous white flowers, eſteemed as furniture for the pleaſure-ground.

Claſs and order, *Decandria Pentagynia.*

*Characters.*] CALIX, a pentaphyllous ſpreading cup. COROLLA, five obtuſe, bifid, patent petals. STAMINA, ten filaments, alternately ſhorter, and roundiſh antheræ. PISTILLUM, an oval germen, five capillary ſtyles, and obtuſe ſtigmas. PERICARPIUM is either an oval, cylindrical, or globular unilocular capſule, and many roundiſh ſeeds.

The ſpecies cultivated in our gardens are,

[1]CERASTIUM *Repens.*

*Repent, or Creeping Hoary Ceraſtium.*] Ceraſtium with creeping perennial roots; many ſlender, trailing, branchy, perennial ſtalks, rooting at the joints, garniſhed with ſpear-ſhaped hoary leaves in pairs oppoſite; and numerous branchy pedunculis, each ſupporting one white flower, ſucceeded by roundiſh capſules.

[2]CERASTRUM *Tomentoſum.*

*Tomentoſe, or Woolly Linaria-leafed Ceraſtium.*] Ceraſtrium with perennial roots; many trailing, branchy, rooting, perennial ſtalks; oblong, narrow, very downy white leaves; and many branching pedunculis, terminated by white flowers, ſucceeded by globular capſules.

The flowers of both ſorts are compoſed of five ſmall petals, and being numerous on the plants are very conſpicuous, appearing in May and June.

The plants are hardy, and proſper any where, and being natives of rocky mountains, they are proper furniture for artificial rock-work, ruins, grottos, &c. and will multiply exceedingly, by their trailing ſtalks rooting as they advance at every joint.

Their propagation is effected with the utmoſt facility, either by ſeeds, or ſlipping their rooting branches, or parting their roots; all of which may be performed either in autumn or ſpring.

CERASUS, the Cherry tree. See PRUNUS.

CERATONIA, the Carob tree, or St. John's Bread, or *Siliqua.*

It is a large evergreen exotic ſhrub of the green-houſe, adorned with pinnated leaves, and ſmall apetalous flowers.

Claſs and order, *Polygamia Trioecia.*

*Characters.*] CALIX, males, females, and hermaphrodite flowers, on diſtinct plants, having large five-parted cups. COROLLA, no petals. STAMINA, five long filaments, and large didymous antheræ. PISTILLUM, a fleſhy germen, long ſtyle, and capitated ſtigma. PERICARPIUM, females, a large, obtuſe, compreſſed pod, divided by tranſverſe partitions, each having one ſeed lodged in a ſweetiſh pulp.

The ſpecies is,

*Ceratonia Siliqua.*] Ceratonia with an upright, woody, thick ſtem, dividing into a branchy head fifteen or twenty feet high; long pinnated leaves, of ſeveral large, thick, firm, duſky green lobes; and ſmall purpliſh apetalous flowers, ſucceeded by large, fleſhy, compreſſed, ſweetiſh, eatable pods.

This ſhrub being a native of the ſouthern parts of Europe, in this country requires ſhelter in winter; ſo muſt be kept in pots, and placed in the green houſe collection.

It is propagated by ſeeds procured from Italy, which ſow in pots in the ſpring, plunging them in a hot-bed; and when the plants are three inches high, prick them in ſeparate ſmall pots, continuing them alſo in a hot-bed, and afford them occaſional ſhade, water, and freſh air, to which harden them gradually in June, and in July remove them abroad to a ſheltered place till October; then place them in the green-houſe, treating them as other ſhrubs of that department.

CERCIS, Judas tree, or *Seliquaſtrum.*

This genus furniſhes two hardy, deciduous, ornamental trees, of moderate ſtature, adorned with heart-ſhaped leaves, and cluſters of pentapetalous papilionaceous-like flowers.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, a monophyllous quinquedented cup, convex at bottom. COROLLA, five petals, reſembling a papilionaceous flower; two of the petals are reflexed and form the wings, a roundiſh one the ſtandard, and three, in form of a heart, form the carina, and ſurround the fructification. STAMINA, ten diſtinct declinated filaments, four of them longer than the reſt, and oblong, incumbent antheræ. PISTILLUM, a narrow, lanceolate, pedicellated germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, an oblong oblique-pointed pod of one cell, and roundiſh ſeeds.

The ſpecies are,

[1]CERCIS *Siliquaſtrum.*

*Siliquaſtrum, or Common European Judas-*

*tree.*] Cercis with an upright trunk, dividing into an irregular branching head, from ten to twenty feet high, garniſhed with round, heart-ſhaped, ſmooth leaves, on long foot-ſtalks, and purple flowers in large cluſters from every ſide of the branches, ſucceeded by long flat pods.

*Varieties.*] With fleſh-coloured flowers—with white flowers—with broad pods.

[2]CERCIS *Canadenſis.*

*Canadian Downy-leaved Judas-tree.*] Cercis with an upright ſtem, branching irregularly, from ten to fifteen feet high; heart-ſhaped, downy, alternate leaves; and reddiſh flowers in cluſters from the ſides of the branches, ſucceeded by long pods.

The flowers of both theſe ſpecies conſiſt each of five petals, are very numerous, and make a fine ornamental appearance in April or May, coming out with the leaves, ſurrounding the branches in cluſters, and are often ſucceeded here by pods and ripe ſeed.

All the ſorts are deciduous, and of hardy temperament.

They are choice furniture as flowering ſhrubs for any ornamental plantation; they are not only beautiful in their numerous early flowers, but the ſingularity of their leaves forms a fine variety, in aſſemblage with other trees and ſhrubs of ſimilar growth; ſo ſhould never be omitted in a collection, particularly for the moſt conſpicuous ſhrubbery compartments.

Their propagation is principally by ſeed; for they do not ſucceed by layers nor cuttings. Sow the ſeed in March in a bed of common earth, covering it half an inch deep; the plants will appear, probably ſome, the ſame year, and the reſt not till the following ſpring, ſo that the bed ſhould not be diſturbed till all are come up, being careful to clear out weeds, and give occaſional waterings in ſummer; and in winter the ſhelter of mats, in very ſevere weather, will greatly protect the tender tops of the ſeedlings, which in March following tranſplant in nurſery rows a foot apart, allowing two feet between the rows, and in about three years they will be of due ſize for the ſhrubbery.

CESTRUM, Baſtard Jaſmine, or *Jaſminoides.*

It retains ſome ſhrubby evergreen exotics for the ſtove ſix or eight feet high, adorned with ſimple, oblong, thick leaves, three or four inches long, and monopetalous funnel-ſhaped flowers in cluſters.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a monophyllous, ſhort, tubular, quinquedented cup. COROLLA, one funnel-ſhaped petal, with a long cylindrical tube, ſpreading above, and divided into five oval ſegments. STAMINA, five filaments adhering to the tube, and roundiſh tetragonous anthers. PISTILLUM, a cylindrical oval germen, ſlender ſtyle, and thick obtuſe ſtigma. PERICARPIUM, an oval unilocular berry, having many roundiſh ſeeds.

The ſpecies are,

[1]CESTRUM *Nocturnum.*

*Nocturnal, or Night-ſmelling Ceſtrum.*] Ceſtrum with an upright, woody, divided, branchy ſtem, ſix or eight feet high; longiſh, ſmooth, firm leaves, veined underneath, and placed alternate; and greeniſh yellow flowers in ſmall cluſters, on footſtalks, from the ſides of the branches.

[2]CESTRUM *Diurnum.*

*Diurnal, or Day-ſmelling Ceſtrum.*] Ceſtrum with an upright, woody, divided, very branchy ſtem, riſing eight or ten feet high; oblong, ſmooth, thick, firm leaves, placed alternate; and cluſters of whitiſh flowers, ſitting cloſe to the branches.

Both theſe ſpecies being natives of the hot parts of America, in this country are retained in ſtoves.

They are evergreen, and form a pretty variety in large ſtoves; both ſorts flower here annually, and have the appellation of Night-ſmelling, and Day-ſmelling, from the remarkable ſtrong fragrance of their flowers reſpectively at theſe times.

They muſt be kept in pots of light freſh earth, watered frequently in ſummer, but moderately in winter.

Both ſorts may be propagated by ſeed and cuttings, by the aſſiſtance of artificial heat; but as ſeeds are with difficulty procured, you may plant cuttings of the ſide-ſhoots five or ſix inches long, in pots of light earth, any time in ſummer, plunging the pots in the bark bed, and give occaſional ſhade and water.

CHAMÆROPS, Dwarf Palm, or *Palmetto.*

It conſiſts of one ſpecies, an acaulis perennial exotic, with large, palmated, fan-ſhaped leaves, and ſpathaceous flowers; a native of Spain, and retained here in our ſtoves for variety.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] CALIX, male and hermaphrodite

phrodite flowers on diſtinct plants, having a compreſſed ſpatha, protruding a branching ſpadix of many florets, each having a triphyllous cup. COROLLA, a branching ſpadix of many erect florets, each divided into three inflexed parts STAMINA, ſix compreſſed filaments, and narrow twin antheræ. PISTILLUM, three roundiſh germina, and three permanent ſtyles, and acute ſtigmas. PERICARPIUM, three unilocular berries, each having a ſingle ſeed.

The ſpecies is,

CHAMÆROPS *Humilis.*]

*Dwarf Palm, or Palmetto.*] Chamærops with a ſpreading root, ſending up frondoſe ſpinous foot-ſtalks, elevating at top; large palmated folded leaves, from ten to eighteen inches long, and near a foot broad, of many foldings, opening like a fan, and divided at top like the fingers of a hand; and between the leaves ariſes a ſpatha, protruding a branching ſpadix of flowers.

This plant rather requires protection of a ſtove while young, but when older, it will proſper in the full air in ſummer, and in a green-houſe in winter, and muſt always be kept in pots of light ſandy earth, frequently watered in ſummer, but moderately in cold weather.

It may be propagated by ſeeds, and by ſlips from the head of the root. The ſeeds are procured from abroad, which ſow in pots of light ſandy earth, and plunge them in a hot-bed, giving occaſional waterings; and by autumn or ſpring following the plants will be fit to be pricked in ſeparate pots. By ſlips the crown of the roots ſometimes afford off-ſets, which, if ſeparated with fibres, planted in pots, and plunged in a hot-bed, will readily grow.

CHARACTERS. The deſcription or generical character of every genus of plants, drawn from the fructification, or all the parts of the flower.

The term *Character* is applied only in deſcribing the *genera*, and never extended to the *ſpecies*; that of the *genus* being always founded on the parts of the fructification, as being invariable; and the deſcription of the ſpecies of each genus, is from ſtriking circumſtances of the root, ſtem, leaves, buds, and mode of flowering, &c. all of which are often very different in different ſpecies of the ſame genus; but as the flower or fructification being unchangeable, that, and none other, is to be employed in eſtabliſhing the genus, and therefore the *characteriſtic* mark of each genus is to be fixed from the figure, ſituation, connection, number, and proportion of all the parts of the flower, as the *calix*, *corolla*, *ſtamina*, *piſtillum*, *pericarpium*, and the *ſemen*, or ſeed; which parts are defined to be the fructification of all vegetables, being a temporary but invariable part appropriated to generation, terminating the old vegetable, and furniſhing ſeed to begin the new; and which *characteriſtic* marks being conſtant throughout the ſpecies of every reſpective genus, and every genus invariable in itſelf, the flower is now univerſally eſtabliſhed as the only proper baſis from which to draw the Characters, to diſtinguiſh all the numerous genera of plants.

But before the invention of a regular ſyſtematic method, Characters were drawn from any, or all the parts of the plant indiſcriminately, as the root, ſtem, leaves, buds, and general habit; a circumſtance ſo variable and uncertain, as explains the great confuſion that ſo long obtained in botany; ſuch deſcriptions being only to diſtinguiſh the different *ſpecies* of a *genus*.

The Characters therefore of every genus are founded on the parts of the flower, which being deſtined for the reproduction of the plant and fruit, muſt neceſſarily be moſt conſtant; and all the ſpecies of every genus, however different in their external habit, which is often very conſiderable, yet they perfectly agree in their fructification: thus, for example, what apparent difference there is betwixt the cabbage, cauliflower, broccoli, and turnep! and yet are all ſpecies and varieties of the genus *Braſſica*, perfectly agreeing in their generical Characters. See GENUS and SPECIES.

CHEIRANTHUS, Wallflower, and Stock-Gilliflower.

The plants are of the flowery tribe, and conſiſt chiefly of herbaceous ſhrubby biennials, perennials, and annuals, of upright branchy growth, from one foot to a yard high, adorned with longiſh narrow leaves, and long erect ſpikes of numerous, four-petalous, very ornamental flowers.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, four ſpear-ſhaped, concave, erect, connivent leaves. COROLLA, four roundiſh petals, placed in form of a croſs. STAMINA, ſix parallel filaments, two rather ſhorter than the other, and erect acute antheræ. PISTILLUM, a long, priſmatic, te-

tragonous germen, the length of the ſtamina, exceeding ſhort ſtyle, and thickiſh, divided, reflexed, permanent ſtigma. PERICARPIUM, a long compreſſed ſiliqua, or pod, containing many compreſſed ſeeds.

There are many ſpecies; but thoſe of moſt merit are, thoſe celebrated beautiful plants, well known by the vague names of Wallflower and Stock-Gilliflower, ſo valuable as ornamental garden-plants, both for the elegance and delightful fragrance of their numerous flowers, and of which modern botaniſts allow but three diſtinct ſpecies; that is, two biennials, or ſometimes perennials, and an annual, each of which, however, admits of many fine varieties.

The Wallflowers are very diſtinguiſhable from the Stocks by their narrow, ſmooth, green leaves, thoſe of the Stocks being broader, thicker, and moſtly of a hoary whitiſh hue.

The ſpecies of our gardens are,

[1]CHEIRANTHUS *Cheiri.*

*Cheiri, Common Cheiranthus, or Wallflower.*] Cheiranthus with ligneous, long, tough roots; an upright, woody, abiding ſtalk, divided into many erect angular branches, forming a buſhy head from one to two feet high, cloſely garniſhed with ſpear-ſhaped, acute, ſmooth, green leaves, and all the branches terminating in long erect ſpikes of numerous flowers, which, in different varieties are Yellow, Bloody, White, &c.

Varieties of this are,

*Common Dwarf Yellow Wallflower*—having a low buſhy ſtem ten or twelve inches high, and ſmalliſh yellow ſingle and double flowers.

*Large Yellow Wallflower*—having a branchy ſtem eighteen inches or two feet high, and large yellow ſingle and double flowers.

*Large Yellow Bloody Wallflower*—having a branchy ſtem from about fifteen inches to two feet high, and yellow blood-ſpotted ſingle and double flowers.

*Bloody Wallflower*—having a branchy ſtem fifteen or eighteen inches high, and large blood-coloured ſingle and double flowers.—This variety, in its true bloody ſtate, is eſteemed the moſt beautiful of all the Wallflower tribe, and its flowers are the largeſt.

*White Wallflower*—having a very branchy greeniſh ſtem about a foot high, narrow ſhining green leaves, and pure white ſingle and double very fragrant flowers—with cream-coloured ſingle and double flowers.

This ſort being rather tender, ſhould have a dry ſoil and warm ſituation, where it will often flower, both in the ſpring, and in autumn and winter.

*Narrow-leafed Straw-coloured Wallflower*—having a buſhy ſtem a foot high, very narrow leaves, and long cloſe ſpikes of ſtraw-coloured ſingle and double almoſt ſcentleſs flowers.

*Variegated-leafed Yellow Wallflower*—having a branchy ſtem twelve or eighteen inches high, garniſhed with gold-ſtriped leaves, and yellow ſingle and double flowers—ſilver-ſtriped leaves, and yellow flowers.

*Winter Wallflower*—having a branchy ſtem a foot or fifteen inches high, and white or yellow ſingle flowers, appearing the beginning of winter, often continuing, if mild weather, till ſpring, when they exhibit a general bloom as the other varieties.

All the above varieties of this ſpecies (Wallflower) are robuſt, buſhy, evergreen, hardy biennials and perennials, very flowery plants, flowering principally in April, May, and June, often exhibiting their flowery ſpikes two or three feet high; the plants growing freely in any common ſoil and open expoſure, are great ornaments to the compartments of the pleaſure-ground. The Double are in moſt eſteem, and more particularly the Double Bloody ſort; but all the varieties effect a fine diverſity, and the Singles of each ſort afford plenty of ſeed for propagation, and from which both ſingle and double flowered plants are produced; and all the ſorts may alſo be encreaſed by ſlips, cuttings, and layers, in a ſhady border in May or June, which is the only method to continue the fine double kinds.

[2]CHEIRANTHUS *Incanus.*

*Hoary Cheiranthus, or Stock-Gilliflower.*] Cheiranthus with ligneous, long, naked, white roots; an upright, ſtrong, woody, abiding ſtem, from one to three feet high, branchy at top, adorned with long, ſpear-ſhaped, obtuſe, hoary leaves; and the top of the ſtalk, and all the branches, terminated by erect ſpikes of flowers, from one to two or three feet long, of different colours, in different varieties.

Varieties of this are,

*Red, or Queen Stock-Gilliflower*—having a robuſt ſtem a foot high, very branchy and buſhy at top, every branch terminated by an erect cloſe ſpike of pale red ſingle and double flowers—bright red ſingle and double flowers—variegated red and white ſingle and double flowers.—This ſort and varieties are remarkable for their prolification in many double-

flowered

flowered plants, from ſeed, and that, if ſown early in ſpring, it flowers a little the ſame year towards autumn, which is a peculiar merit in this ſort, becauſe the double flowers of the ſame year's ſeedlings, diſcovering themſelves at that time, we take them up with good balls to their roots, and pot them, to move to occaſional ſhelter from froſt, whereby they flower earlier, and much ſtronger in ſpring, than thoſe that are fully expoſed, eſpecially in ſevere winters, when the Stocks in general are ſometimes conſiderably cut.

*Scarlet, or Brompton Stock-Gilliflower*—having a ſtrong unbranching ſtem from one to three feet high, crowned by a cluſter of long thick leaves; and from the centre an erect flower-ſtalk two or three feet long, iſſuing forth ſeveral ſide-branches, all of which, and the main ſtalk, forming beautiful erect ſpikes of large ſcarlet ſingle and double flowers.

This in its double ſtate makes a moſt ſuperb appearance, and is the grandeſt of all the *Cheiranthus* kind, the flowers being often as large as ſmall roſes, numerous and cloſely placed, diſcloſing themſelves in ſucceſſive order upward, according as the ſpikes gradually advance in height, which, when at full length, frequently ſhow the plant upward of four feet high, exhibiting a full bloom five or ſix weeks.

*Purple, or Twickenham Stock-Gilliflower*—having a thick ſtem a foot and half, or two feet high, very branchy upward, and all the branches terminated by erect ſpikes of purple ſingle and double flowers——purple blood-ſpotted ſingle and double flowers—variegated purple and white flowers.

*White, or Shrubby Stock-Gilliflower*—having a ſhrubby firm ſtem, from a foot to a yard high, divided and ſubdivided into many ſhort branches, forming a buſhy ſhrub-like head, very ſhining green leaves, and all the branches terminated by erect ſpikes of pure white ſingle and double flowers—whitiſh fleſh-coloured flowers—whitiſh purple flowers—whitiſh red ſpotted flowers.—This ſort and varieties are remarkable for becoming ſhrubby, and of ſeveral years duration in a dry ſoil, and for affording many double-flowered plants from ſeeds.

All the above varieties of this ſpecies *(Cheiranthus Incanus)* are hardy, evergreen, very flowery, ornamental biennials and perennials, and grow freely in the open ground, and are great ornaments to the pleaſure-ground in May, June, and July, exhibiting their bloom from two to four feet high: the double kinds are ſingularly beautiful; but all the ſorts form a fine variety, and the ſingles produce plenty of ſeed in autumn, and from which both ſingle and double-flowered plants are annually produced.

[3]CHEIRANTHUS *Annuus.*

*Annual Stock-Gilliflower, or Ten-Weeks-Stock.*] Cheiranthus with an upright, woody, ſmooth ſtalk, divided into a branchy head, a foot or fifteen inches high, garniſhed with ſpear-ſhaped, blunt, a little indented, hoaryiſh leaves, and all the branches terminated by long erect ſpikes of numerous flowers, of different colours in different varieties.

Varieties of this are,

*Common Hoary-leafed Ten-Weeks-Stock*—having hoaryiſh leaves, and purple ſingle and double flowers—red ſingle and double flowers—white ſingle and double flowers.

*Pruſſian Wallflower-leafed Ten-Weeks-Stock*—having ſmooth, bright, green leaves, and pure white ſingle and double flowers—purple ſingle and double flowers.

All theſe varieties proſper in the full ground, and flower beautifully from July till autumn, and the ſingles afford abundance of ſeed, and from which both ſingle and double kinds are always produced; for being annual, they can only be continued by ſeed ſowed annually in ſpring.

[4]CHEIRANTHUS *Maritimus.*

*Maritime Dwarf Annual Cheiranthus, or Virginia Stock-Gilliflower.*] Cheiranthus with ſlender, herbaceous, very branchy, diffuſe ſtalks, ſix or eight inches high; ſmall, ſpear-ſhaped, cloſe-ſitting leaves; and all the branches terminating in ſhort looſe ſpikes of many ſmall, purple, ſingle flowers, having eminent antheræ.

The flowers of all theſe four ſpecies, and numerous varieties, are produced in erect ſpikes, from half a foot to a yard long, each ſpike having many flowers, eſpecially all thoſe of the firſt three ſpecies; and thoſe of the doubles are generally the moſt numerous, largeſt, more cloſely-placed, and of longeſt duration. The ſingle flowers are compoſed ſeparately of four broad petals, ſee their *Characters*; but in the doubles, the petals are multiplied in many ſeries to the very centre, to the total excluſion of the fructification, ſo conſequently afford no ſeed; the ſingles however afford plenty, and from which, plants of both ſorts are obtained. The double flowered kinds are very diſtinguiſhable at the firſt appearance of the flower-bud, which is more robuſt, larger, and ſwelling, than thoſe of the ſingles.

The

The firſt and ſecond ſpecies, *Wallflower*, and *Stock-Gilliflower*, and all their reſpective varieties, may be conſidered both as biennials and perennials, with abiding ſtalks, garniſhed with leaves the year round, and very profuſe in moſt fragrant flowers. Conſidered as biennials, the plants being raiſed from ſeed in ſpring, attain nearly their full growth by autumn, ſtand the winter, and in ſpring following ſhoot up their flower-ſpikes which gradually advance in height, and the flowers continue opening till June, and which are ſucceeded by ripe ſeed in July, Auguſt, and September; ſoon after which the plants frequently periſh, eſpecially when growing in rich moiſt ground; or, if they ſurvive another year, they generally aſſume a dwindling growth, become ſtraggling and irregular, and flower weak and inconſiderably. As to their perennial property, being raiſed as above, and planted in a dry, rubbiſhy, gravelly, or any poor lean ſoil, they generally effect a ſtunted growth, become ſhrubby and perennial, of ſeveral years duration, and flower annually, as is evident by thoſe which grow naturally out of the crevices of walls, ruins, and old buildings, in many parts of England, particularly the Wallflowers; hence they derived the name; though the Stocks will alſo grow in the ſame manner, with ſhort, ſtunted, ſtocky ſtems; hence we ſuppoſe they obtained the appellation of ſtocked, or Stock-Gilliflower: however, when cultivated either in good or bad earth, and whether of two or more years duration, moſt of the ſorts, both Walls and Stocks, generally flower ſtrongeſt, and in greateſt beauty, the firſt year of flowering; therefore, to have a conſtant ſucceſſion of plants to flower in perfection, a ſupply muſt be annually raiſed from ſeed in April or May for next year's bloom, though the Wallflowers may be encreaſed by planting ſlips of their young ſhoots in May, which is the only method to propagate the double kinds; for the Walls are not very prolific in doubles from ſeed: the ſtocks may alſo be continued by ſlips, but theſe never ſucceed near ſo well as the Walls; beſides, the different varieties of Stocks are often very profuſe in double flowered ſeedlings, which renders the other practice unneceſſary; and the Queen Stock, White Stock, and the Twickenham Purple, frequently have one third, or half their ſeedlings double; but the White Stock moſt of all.

All the varieties of the above two ſpecies proſper freely in the open border, in any common ſoil and open expoſure, though, when growing in rich moiſt land, they, acquiring a luxuriance of growth, are more liable to injury, from the power of ſevere froſt, but more particularly the ſtocks; and in both ſpecies the double varieties are more liable to ſuffer than the ſingle kinds, ſo that ſome of the fineſt doubles ſhould always be potted, to move to occaſional ſhelter of a deep frame, to be covered with glaſſes or mats, in time of ſevere weather in winter, but muſt be fully expoſed in all mild weather.

The third ſpecies, *Ten-Weeks-Stock* and varieties, is but of one ſummer's duration, riſing from ſeed in ſpring, and periſh at the firſt attack of hard froſt in winter. All the varieties of this ſpecies are of hardy growth, and moſt beautiful annuals, very profuſe in moſt elegant ſpikes of flowers great part of ſummer and autumn, and the plants proſper in the open borders, and make a fine appearance, particularly the double kinds; and all the varieties are eaſily raiſed from ſeed in the common ground in ſpring, or may be forwarded in a hot bed, and, in either method, being planted out in the borders in May or June, they flower in July, and by two or three different ſowing, at a month or ſix weeks interval, from February to May, a ſucceſſion of full blowing plants may be obtained from July until December.

The fourth ſort, *Cheiranthus Maritimus*, is but of few months duration; it, however, conſidering its diminutive ſtature, is a very flowery plant, and proper to ſow in patches, to adorn the fronts of borders, which, by a repetition of three ſowings from February to May, will afford a ſucceſſion of bloom from June till October.

It is alſo ſome times ſowed to form a ſummer edging in ſmall gardens, which, during its bloom, is very pretty.

### *Propagation of the firſt two Species.*

The two firſt ſpecies, and all their reſpective varieties, are propagated plentifully from ſeed, in the common ground in ſpring, for tranſplantation; and from the ſeedlings both ſingle and double-flowered plants are obtained; but the Stocks are conſiderably more prolific in doubles than the Walls: however, when fine doubles of theſe are obtained from ſeed, &c. they may be multiplied at pleaſure by ſlips of their young ſide ſhoots early in ſummer; for all the ſorts of Wallflowers, both ſingle and double, grow freely by ſlips: but

But as to Stocks, although they will alſo grow by ſlips, they do not make near ſuch progreſs as the others, nor do they ever grow freely, nor make ſuch thriving plants; but this is no great loſs, ſince the ſeedlings ſeldom fail to afford great plenty of doubles.

Firſt, of raiſing both ſpecies from ſeed, obſerving that the plants raiſed one year flower the next.

The ſeed of all the varieties may be had cheap enough of all the nurſerymen; but the great article is to procure ſuch that have been ſaved from the fineſt of each reſpective variety. See *Saving the Seed.* The time for ſowing is as follows: the Wallflowers may be ſown any time in April; though in very rich ground, from about the 20th of that Month to the 15th of May is the moſt proper time to ſow both ſorts, for if ſowed ſooner in a rich warm ſoil, the plants are apt to acquire a too great luxuriancy of growth, and thereby ſubject to ſuffer by ſevere froſt and exceſſive wet in winter. For the reception of the ſeed chuſe a ſpot of undunged light earth, in a quite open ſituation, and, as ſoon as dug, ſow the ſeed on the ſurface, each ſort ſeparate, and rake it in light and evenly. The plants will riſe in a fortnight, when, if dry weather prevails, give frequent waterings, and in July, or when they are about three inches high, a quantity of the ſtouteſt ſhould be thinned out in a moiſt time, and planted ſingly in different parts of all the borders, and the other compartments of the pleaſure ground, where it is deſigned they ſhall flower, which all the ſorts will effect the following ſpring and ſummer. Or the Wallflowers may be pricked in nurſery-beds nine inches diſtance till October, then finally tranſplanted with balls to their roots; though where there is room in the borders at the time above-mentioned, it is moſt adviſeable to plant out moſt of theſe plants at once while young, where they are to remain, becauſe they do not ſucceed ſo well by removals, eſpecially the ſtocks, as having long ſticky roots, ill furniſhed with fibres; but the plants of both ſpecies, when removed large, unleſs with good balls, never take root ſo freely, nor eſtabliſh themſelves ſo firmly, nor are of ſo long duration, as when planted out finally at the period of growth firſt adviſed.

The Wallflowers however ſucceed much better by removals than the Stocks, their roots being more fibrey, and upon particular occaſions might even, when of pretty large growth, or when juſt ready to bloom, be removed where wanted with balls to their roots; but thoſe of the Stocks being ſo ſcanty of ſmall fibres, that the plants, when large, rarely riſe with good balls, without the greateſt care in digging wide and deeply round them.

Where the above two ſpecies are raiſed for ſale, as is greatly practiſed by the ſetting-gardeners in the vicinity of London, the plants from the ſeed bed are pricked or planted out in nurſery-beds, in rows nine inches or a foot diſtance, and the ſame diſtance in the lines; and if they here aſſume a luxuriancy of growth, they ſometimes tranſplant them again about the end of Auguſt into other beds, as above, eſpecially the Wallflowers, to check their luxuriancy, and promote their growing buſhy, to render them more marketable; for vaſt quantities of theſe plants are brought to Covent-Garden, and the other gardeners markets in London, in the ſpring of the year, for ſale, juſt as they begin to ſhew bloom, when the colours and properties of the flowers are diſcoverable, all brought with ſmall balls of earth to their roots, for they will not buy them without, and are there ſold, the ſingle kinds for a ſhilling or eighteen-pence per dozen, but the fine doubles are commonly brought in pots, and one plant of which often fetches as much, or more, than a dozen of the others.

If it is deſigned to cultivate any of theſe plants upon walls, ruins, or rock-work, for variety, it is moſt eligible to ſow the ſeed where the plants are to remain, ſowing it in the crevices in autumn or ſpring, covering it with any kind of dry earth a quarter of an inch deep, and leave it to nature, where the plants will come up, flower, and ſcatter their ſeeds, and propagate themſelves, and endure for years.

If ſeeds of any of the ſorts are ſown in any rubbiſhy or poor ſoil, and the plants thinned and permitted to remain unremoved, they are commonly of longer duration than thoſe that are tranſplanted.

When intended to ſhow a bloom of any of the double ſeedlings in pots, they may be potted with balls to their roots as ſoon as they ſhew their double flower-buds; but as the Stocks remove rather badly when large, and as they are conſiderably more prolific in doubles than the Walls, you may alſo, at the time of tranſplanting from the ſeed bed, plant ſome in large pots, three or four in a pot, and it is probable one or more in each pot may prove

doubles,

doubles, particularly the Queen, Purple, and White Stock; ſo that as ſoon as the doubles are diſcoverable, cut the others off cloſe to the bottom.

*Propagation by Slips.*

The propagation by ſlips or cuttings is practiſed principally for multiplying the fine double kinds, but chiefly for the Wallflowers, for the reaſons already hinted: the time of year for this work is April, May, and June, though they generally afford the beſt ſlips in May; theſe are the young ſide-ſhoots without flowers, three, four, or five inches long, which ſlip or cut off cloſe to the branches, diveſt them of the lower leaves, and plant them in a ſhady border ſix inches diſtance, and two, three, or four inches deep, according to their length, giving occaſional waterings in dry weather, where they will readily form roots, ſhoot at top, and make good plants by October, when the fine ſorts ſhould be each planted ſeparately in pots, to move to occaſional ſhelter of a frame during winter, covering them only in time of hard froſt, and they will all flower the ſpring following.

All the varieties may alſo be propagated by layers of their young pliable branches in May and June, as practiſed for carnations; but the raiſing them from ſlips is the more ready and expeditious method, and generally productive of the beſt plants.

To continue a ſtock of handſome ſtrong flowering plants of all theſe ſorts, always raiſe a ſupply annually both from ſeeds and ſlips, &c. for, although the plants ſometimes live two, three, or more years, they always exhibit the fineſt bloom the firſt ſeaſon of flowering.

All the double plants that are retained in pots ſhould be moved to a place of occaſional ſhelter in winter, either in a deep frame, or plunge them in a warm border, and arch them over with hoops; and in froſty weather, if in a frame, cover with the glaſſes, or, if under arches, with mats, and with long litter over either of theſe, when the froſt is very ſevere.

*Propagation of the third and fourth Species.*

The third ſpecies, *Ten-Weeks-Stock*, is propagated by ſeed for tranſplantation, any time from the middle of February to the middle or end of May; and by three different ſowings in that period of time, you will obtain plants, exhibiting a conſtant bloom from July till almoſt Chriſtmas.

The ſeed will grow freely on a warm border, eſpecially thoſe ſown after the middle of March; but to have the plants as forward as poſſible, I ſhould adviſe the firſt ſowing to be in a moderate hot-bed, or, in default thereof, in a frame, or under a hand-glaſs, for ſhelter on nights during the cold weather, ſowing it on the ſurface, and either rake it in lightly, or cover it with fine earth a quarter of an inch deep; and when the plants have ſeveral leaves, about two or three inches high, take the opportunity of moiſt weather to plant them out at once into the borders or places where you deſign they ſhall flower, giving a little water, and they will ſoon take root, and grow freely without farther trouble.

If you deſign to exhibit a blow of theſe plants by themſelves, plant them in four feet wide beds, in rows a foot aſunder, allowing the ſame diſtance in the rows.

When it is intended to have a ſhew of double kinds in pots, then either at the time of planting out, ſet three plants in each pot, and as ſoon as they ſhow bloom, it is probable one or more of the three will be double, when the others may be cut away, not pulled up, becauſe of diſturbing the roots of the remaining ones; or, if the plants are in beds, ſome of the doubles, as ſoon as diſcoverable, may be taken up with good balls, and plant one in each pot, give water, and place them in the ſhade a week or two.

The fourth ſort, *Dwarf Virginia Stock*, is raiſed from ſeed, ſown a quarter of an inch deep in the places where the plants are to remain, either in patches in the fronts of borders, or as an edging, as already obſerved.

*Saving Seed of all the Sorts.*

All the ſorts afford ſeed plentifully in their ſingle ſtate; the doubles none at all; and it ripens abundantly in June, July, and Auguſt.

In order to continue a ſucceſſion of the fineſt ſorts of the three firſt ſpecies and varieties, you ought to be choice in the plants from which to ſave ſeed: the largeſt plants therefore of each reſpective variety of ſingles, and with the largeſt flowers of the deepeſt or brighteſt colours, are to be marked; and where you diſcover any with flowers that exhibit a tendency towards a ſemi-double ſtate, theſe are alſo particularly to be choſen; that is to ſay, the ſingles having naturally but four petals, but ſometimes here and there one will ſport, and have five, ſix, or more, approaching to half doubles; and ſeeds ſaved from ſuch kinds, are always more prolific in double-flowered plants than that of the entire ſingle flowers: likewiſe good ſingle plants,

plants, growing close to, or very near doubles of the same kind, are also proper to mark for seed; and all bad kinds, particularly singles, growing near the chosen seed-plants, should be cleared away. By observing the above hints, you cannot fail of continuing an annual shew of these flowers in their greatest perfection.

According as the seeds ripen, cut off the branches in dry weather; tye them by the ends in small bunches, and hang them up in a dry but airy place, and when properly dried rub out the seed, and put it up in paper bags till spring.

CHELIDONIUM, Celandine, and *Glaucium*, or Horned-Poppy.

This genus furnishes hardy herbaceous perennials, biennials, and annuals, of the flowery tribe, obtaining from about eighteen inches to a yard in stature, ornamented with large divided leaves, and large, four-petalous, yellow and scarlet flowers.

Class and order, *Polyandria Monogynia.*

*Characters.*] CALIX, two oval, concave, caduous leaves. COROLLA, four large, roundish, plane, spreading petals. STAMINA, numerous filaments, and oblong, compressed, twin antheræ. PISTILLUM, a cylindrical germen, no style, but a headed bifid stigma. PERICARPIUM, a cylindrical bivalvular pod, having many seeds.

The species of note are,

[1]CHELIDONIUM *Majus.*

*Greater Common Perennial Celandine.*] Chelidonium with a thick knobby root; upright, round, branching, hairy stalks, two or three feet high; large, many-lobed leaves; and at top of the stems and branches umbellated foot-stalks, supporting large yellow flowers.

*Varieties.*] Greater Celandine with jagged leaves, and double yellow flowers——with striped jagged leaves.

[2]CHELIDONIUM *Glaucium.*

*Glaucium, or Biennial Chaledonium, called Horned-Poppy.*] Chelidonium with upright, robust, round, smooth stalks, divided into many branches two feet high; pinnatifid lower leaves, those above lobated, and their base embrace the stalks; and from the axillas of the leaves, single foot-stalks, supporting each one large yellow flower, succeeded by long horn-shaped pods nine or ten inches in length.——Hence the appellation Horned-Poppy.

It flowers in June and July, and ripens abundance of seeds, and being a biennial, dies soon after.

[3]CHELIDONIUM *Corniculatum.*

*Corniculated Annual Chelidonium, or Scarlet Horned-Poppy.*] Chelidonium with upright rough stalks half a yard high; large, pinnatifid, finely-jagged, many-pointed, hairy, close-sitting leaves; and scarlet flowers of short duration, succeeded by long corniculated, or horn-shaped, pods.

The flowers of all these species in their natural state are composed of four large, roundish, spreading petals; but in the double kind the petals are numerous.

They are all very hardy plants, and prosper in any common soil.

The first species grows wild in shady lanes, sides of banks, and such-like uncultivated places; is valuable in medicine, but in its common state is rarely admitted into gardens. The double-flowered variety, however, merits culture as a flowery perennial for large borders, and may be multiplied abundantly by dividing the roots in autumn or spring.

The second sort, *Chelidonium Glaucium*, merits notice both as a flowery biennial, and for the singularity of its long horned pods; it inhabits the sea coasts, but has been long admitted in gardens, and grows freely in the borders, or in rock-work, &c. It is propagated plentifully by seed in autumn or spring, sowed either where the plants are to remain, or for transplantation; they come up one year, flower the next, and soon after perish; so must be raised annually from seed.

The third sort will form a variety in the borders among other hardy annuals, and should be sowed in February or March a quarter of an inch deep, in patches where they are to remain.

CHELONE, *Chelone.*

It consists of three herbaceous flowery perennials, with upright stalks two feet high, decorated with spear-shaped leaves, and beautiful spikes of monopetalous, ringent, different-coloured flowers, in autumn.

Class and order, *Didynamia Angiospermia.*

*Characters.*] CALIX, a monophyllous, quinquepart, permanent cup. COROLLA is monopetalous and ringent, with a short tube, swelling at the mouth, the upper lip obtuse and indented, the under one slightly trifid. STAMINA, two long and two short filaments, inclosed in the back of the corolla, and incumbent antheræ. PISTILLUM, an oval germen, slender style, and blunt stigma. PERICARPIUM, an oval bilocular capsule, and numerous, roundish, bordered seeds.

The ſpecies are,

[1]CHELONE *Glabra.*

*Smooth Acadian Chelone.*] Chelone with thick very creeping roots; many upright, ſmooth, channelled ſtalks, two feet high, garniſhed with ſpear-ſhaped, pointed, ſerrated, cloſe-ſitting leaves, in pairs oppoſite; and all the ſtalks terminated by cloſe ſpikes of flowers, of different colours, in different varieties.

*Varieties.*] Smooth Chelone with white flowers——with roſe-coloured flowers—with red flowers—with purple flowers.

[2]CHELONE *Hirſuta.*

*Hairy Virginian Chelone.*] Chelone with ſpreading roots; upright very hairy ſtalks two feet high, garniſhed with ſpear ſhaped, hairy, oppoſite leaves; and all the ſtalks terminated by ſpikes of flowers, of different colours, in different varieties.

*Varieties.*] Hairy Chelone with white flowers—with blue flowers—with red flowers—with purple flowers.

[3]CHELONE *Penſtemon.*

*Penſtemon, and the Aſarina Erecta of Miller.*] Chelone with upright branchy ſtalks a foot and half high, adorned with ſpear-ſhaped, pointed, oppoſite leaves, their baſe embracing the ſtalk, and ſhort looſe ſpikes of purple flowers from the forks of the branches.

The flowers of all theſe ſpecies and varieties are of the ringent or gaping kind, many upon each ſpike, which in all the varieties appear from September till November, and are ſometimes ſucceeded by ripe ſeeds in England.

They are all very hardy, and grow freely in the open ground, in any ſoil and expoſure.

They are choice furniture for the pleaſure-ground, particularly the two firſt ſorts and varieties, their flowers exhibiting a very ornamental appearance for two months in autumn, after the principal bloom of moſt other flowers are paſt; and being of different colours, they form a fine variety with each other, and the plants may be readily encreaſed at pleaſure, to furniſh all the different compartments abundantly.

The propagation of the two firſt ſorts, and all the varieties, is by roots, which multiply exceedingly, and may be parted in autumn, or early in ſpring.

The third ſort being rather biennial, muſt be raiſed annually from ſeed, which, if ſown in autumn as ſoon as ripe, the plants will readily riſe the following ſpring, and in June or July may be planted out in the borders.

CHENOPODIUM, Gooſe-foot, or Wild Orach.

This genus retains hardy herbaceous plants for culinary and ornamental uſes, and ſhrubby evergreens for the green-houſe.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, five oval, concave, permanent leaves. COROLLA, no petals. STAMINA, five filaments, and roundiſh didymous antheræ. PISTILLUM, an orbiculate germen, ſhort, two-parted ſtyle, and blunt ſtigmas. PERICARPIUM, none; a ſingle ſeed lodged in the calix.

The ſpecies are,

[1]CHENOPODIUM *Bonus-Henricus.*

*Good-Henry, All-Good, or Common Engliſh Mercury.*] Chenopodium with large, triangular, arrow-pointed, entire leaves, from the root; upright, thick, ſtriated ſtalks, garniſhed with triangular leaves, and terminated by cloſe ſpikes of apetalous yellowiſh-green flowers in June and July, ſucceeded by ripe ſeeds in Auguſt.

It grows wild by way ſides and in bye-lanes, but is ſometimes cultivated in gardens as an eſculent herb, to uſe for culinary purpoſes like ſpinach.

The three following are hardy ornamental annuals.

[2]CHENOPODIUM *Scoparia.*

*Belvedere, or Annual Mock Cypreſs.*] Chenopodium with upright ſtalks, cloſely branching pyramidally from the bottom upward, forming a regular pyramid two or three feet high, fully garniſhed with very narrow, ſpear-ſhaped, plane, entire leaves, and ſpikes of ſmall greeniſh flowers.

The merit of this annual is in its beautiful pyramidal growth, reſembling a young cypreſs tree, and is very ornamental; flowers in July, and ripens abundance of ſeed in autumn.

[3]CHENOPODIUM *Botrys.*

*Botrys, or Multifid-ſpiked Annual Chenopodium, called Oak of Jeruſalem.*] Chenopodium with upright branchy ſtalks near a foot high, garniſhed with oblong, ſinnuated, oak ſhaped, fragrant leaves, and multifid naked ſpikes.

[4]CHENOPODIUM *Ambroſioides.*

*Ambroſia-ſcented Annual Chenopodium, called Oak of Cappadocia.*] Chenopodium with upright ſtalks two feet high; ſpear-ſhaped, indented, odoriferous leaves; and ſingle leafy ſpikes.

Theſe laſt two annuals are eſteemed principally for the fragrance of their leaves; they flower in July and Auguſt, ſucceeded by ripe ſeeds in September.

The

The two following are ſhrubby perennials of the green-houſe.

[5]CHENOPODIUM *Fruticoſum.*

*Shrubby Mexican Chenopodium.*] Chenopodium with ſhrubby, durable, branchy ſtalks, four or five feet high; ſpear-ſhaped, indented, fragrant leaves.

[6]CHENOPODIUM *Multifidum.*

*Shrubby Multifid Chenopodium of Bonaria*] Chenopodium with ſhrubby durable ſtalks three or four feet high; multifid, or divided leaves, of many narrow ſegments.

The flowers of all theſe ſpecies are apetalous, i e. not adorned with petals, ſo make no ornamental appearance.

The firſt ſpecies, *Good-Henry*, when intended to cultivate it as an eſculent, ſow it annually in Auguſt, or early in ſpring, in an open ſpot, and rake it in, and thin the plants to ten or twelve inches diſtance.

The *Belvedere*, and the other two annual ſpecies, are raiſed from ſeed in the full ground in March, ſowing it on a bed of rich light earth, and rake it in lightly; and when the plants are two or three inches high, plant them out ſingly in different parts of the borders; or the ſeed may be ſown half an inch deep, in patches where the plants are to flower, thinning them to a ſingle plant in each place. Some of the *Belvedere* plants may alſo be potted, in which they have a fine effect, in aſſemblage with other potted annuals, in adorning any particular compartment.

The ſcattered or ſelf-ſown ſeeds of the *Belvedere*, in autumn, frequently grow, and the plants riſe ſtrong in the ſpring.

The two ſhrubby green-houſe ſpecies, are eaſily propagated by ſlips or cuttings of their branches, planted in pots of light mould any time from March till June, which, if plunged in a moderate heat, it will greatly forward them.

CHIONANTHUS, Snow-Drop-tree, or Fringe-tree.

This genus conſiſts of one deciduous flowering ſhrub, adorned with large ſimple leaves, and cluſters of ſnow-white fringed flowers.

Claſs and order, *Diandria Monogynia.*

*Characters.*] CALIX, monophyllous, erect, four-parted, and permanent. COROLLA, a funnel-ſhaped petal, divided at top into four long, narrow, erect ſegments. STAMINA, two ſhort filaments inſerted in the tube of the corolla, and heart-ſhaped antheræ. PISTILLUM, an oval germen, one ſtyle, and blunt trifid ſtigma. PERICARPIUM, an unilocular berry, including one hard ſeed.

The ſpecies is,

CHIONANTHUS *Virginica.*

*Virginia Snow-Drop-tree.*] Chionanthus with an upright rough ſtem, dividing into a moderately branchy head eight or ten feet high, garniſhed with large laurel-ſhaped leaves, and from every part of the branches long bunches of very white flowers on trifid foot-ſtalks.

This is a moſt beautiful ſhrub for the ornamental plantations of the pleaſure-ground, and will proſper in any common ſoil, though it delights moſt in that of a ſomewhat moiſt loamy nature. Let it however be placed conſpicuouſly, and if ſo as to have the ſhelter of other ſhrubs, there will be the greater chance of its exhibiting a more plentiful bloom.

The propagation of this ſhrub is by ſeed, and layers of its young branches; though by this method they emit roots very ſparingly, and rarely in leſs than two years.

The ſeed is procured from America by the ſeedſmen, which rarely grows the firſt year. Let it however, as ſoon as it arrives, be ſown in large pots of freſh loamy earth half an inch deep, and plunge them in a ſhady border, giving occaſional weeding and watering till October; then move them to a frame, or where they can be occaſionally ſheltered during hard froſt in winter; and if in March you plunge them in a hot-bed, it will bring them up freely; which harden gradually to the full air, and give occaſional ſhade from the mid-day ſun at their firſt appearance, and water during ſummer, and ſhelter of a frame again from October to April, when the ſeedlings may be pricked ſeparately in ſmall pots, obſerving the above care for another year or two, then may tranſplant them into the full ground.

By layers, chuſe the young twigs of laſt ſummer, and, as they emit roots reluctantly, it is eligible to give ſome a flit, others a twiſt, at the part to be laid in the earth; give plenty of water during ſummer, and in two years it is probable ſome will be rooted.

CHRYSANTHEMUM, Corn Marigold, *(Chryſanthemum).*

The plants are moſtly herbaceous, and furniſh ſome beautiful flowery annuals and perennials for the pleaſure-ground, and ſome of ſhrubby growth for the green-houſe; all of which are upright, very branchy, and from two to four feet high, adorned moſtly with finely divided leaves, and compound, radiated, white and yellow flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, a compound radiated flower, having a hemiſpherical, imbricated cup. COROLLA, many hermaphrodite and female florets; the former are ſmall, funnel-ſhaped, five-parted at top, and form the diſk; and the females are oblong, ligulated, triparted at the end, and compoſe the circumference or ray. STAMINA, five ſhort filaments, and tubular antheræ. PISTILLUM, an oval germen, ſimple ſtyle, and two obtuſe ſtigma. PERICARPIUM, none. SEMINA, a naked ſingle ſeed to each floret.

There are near twenty ſpecies; but as the greater part are of no merit in gardening, and ſome are common weeds of our fields, ſuch as the Common Corn Marigold, and greater Wild Daiſy, &c. we ſhall omit them here, and only introduce thoſe that have merit as garden plants.

The firſt following is that elegant hardy annual, diſtinctively called *Chryſanthemum.*

[1]CHRYSANTHEMUM *Coronarium.*

*Coronated Annual Chryſanthemum.*] Chryſanthemum with a ſingle upright ſtalk from the root, divided into numerous erect branches a yard or more high, garniſhed with pinnatifid deeply-cut leaves, having the exterior ſegments broadeſt, and all the branches and ſide-ſhoots crowned by elegant compound flowers, of different colours and properties, in different varieties.

*Varieties of this are*] Coronated Chryſanthemum with white ſingle and double flowers —cream-coloured ſingle and double flowers— yellow ſingle and double flowers—yellow and white ſingle and double flowers—brimſtone-coloured ſingle and double flowers—fiſtular, or quilled flowers, having all the florets hollow like a quill or pipe—with finely jagged leaves, and flowers of all the above colours and properties.

The flowers of all theſe varieties, in their natural ſingle ſtate, exhibit a round open diſk or middle, compoſed of numerous, ſmall, tubular florets, and one or two ſeries of long flat florets form the circumference or radius; but in the double flowers, the middle or diſc is generally filled with the radius, and ſome are rendered as completely double as the fineſt ranunculus, and the impletion is remarkably regular and beautiful; but it is obſervable, that the firſt flowers are never ſo full and double as thoſe which ſucceed them on the ſame plant.

All the varieties begin flowering in July; the flowers are exceeding numerous, and exhibit a conſtant ſucceſſion of full-bloom till November, and both ſingle and double are ſucceeded by abundance of ſeed.

The three next following are hardy perennials.

[2]CHRYSANTHEMUM *Seretinum.*

*American Daiſy-flowered Chryſanthemum.*] Chryſanthemum with a very creeping root; upright ſtrong ſtalks a yard high, divided upward into branches; broad lower leaves ſawed on the edges, thoſe above ſpear-ſhaped, ſerrated, and pointed; and each branch crowned by a large white flower.

*Varieties.*] With double flowers——with deeply jagged leaves.

[3]CHRYSANTHEMUM *Monſpelienſe.*

*Montpelier Daiſy-flowered Chryſanthemum.*] Chryſanthemum with upright branchy ſtalks three or four feet high; palmated lower leaves of many pennatifid lobes, thoſe above finely divided; and all the branches terminated by large, white, radiated flowers, on long foot-ſtalks.

[4]CHRYSANTHEMUM *Corymbiferum.*

*Corymbus-flowering Chryſanthemum*] Chryſanthemum with upright ſtalks half a yard high; winged leaves, the lobes cut and ſerrated; and the ſtalks terminated by large white flowers in a ſort of corymbus.

The flowers of the laſt three ſpecies are ſhaped like the wild white daiſy, but much larger, having large yellow diſcs, and white radii or rays, appearing in ſucceſſion from July till September.

The two following are ſhrubby green-houſe plants.

[5]CHRYSANTHEMUM *Fruteſcens.*

*Shrubby Canary Chryſanthemum.*] Chryſanthemum with a ſhrubby ſtalk, divided into a branchy head, two feet high, adorned with narrow, thick, ſucculent, indented leaves, three-parted at the ends; and ſmall white flowers, growing ſingly on naked foot-ſtalks from the axilla of the leaves, appearing at moſt times of the year.

[6]CHRYSANTHEMUM *Floſculoſum.*

*Shrubby Floſcular Chryſanthemum.*] Chryſanthemum with a ſhrubby ſtalk, divided upward into a branchy head two feet high; oblong, indented, cloſe-ſitting leaves; and from the axilla of the leaves globular deep yellow flowers, having no rays, but compoſed wholly of floſcular or hollow hermaphrodite florets, appearing from June till November.

The firſt ſpecies, *Chryſanthemum Coronarium,* is a valuable annual for the common borders, and

and other quarters of the pleaſure-ground, being grandly ornamental in a great profuſion of flowers from July till the approach of winter; and each variety is remarkably prolific in doubles, with this peculiar property, that, although the flowers at their firſt appearance often exhibit themſelves ſcarcely ſemi-double, the ſucceeding ones on the ſame plants improve more and more double to the very laſt. This ſort is commonly deemed an annual, as, riſing from ſeed in ſpring, producing flowers and ſeed the ſame year, and periſhing at the firſt attack of froſt; yet cuttings of its branches potted in autumn, to move to ſhelter in winter, take root, and continue till next year, and flower earlier by a month than the ſeedlings. See their *Propagation*.

The ſecond, third, and fourth ſorts, are hardy, herbaceous, flowery perennials, proper for the compartments of large pleaſure-grounds; they will encreaſe the variety by an autumnal bloom of two or three months duration, and will grow any where.

The two ſhrubby ſorts require ſhelter in winter, and, being ornamental, are proper for the green-houſe collection, ſo muſt be always retained in pots of good earth, and managed as other ſhrubby exotics of the green-houſe.

*Propagation of all the Sorts.*

Firſt, of the annual ſort, *Chryſanthemum Coronarium*.

This annual and varieties are raiſed abundantly from ſeed, either in a hot bed or warm border, in the ſpring, for tranſplanting; alſo by cuttings and ſlips of their branches in autumn.

By ſeed, it may be ſown in March or April, and to bring the plants as forward into flower as poſſible, it ſhould be ſown in a moderate hot-bed with other annuals of ſimilar quality, ſuch as the African Marigold, &c. See ANNUAL PLANTS. Or, in default of that convenience, ſow it in a warm border under a hand-glaſs; though, if ſown in a warm place in the middle of April, the plants will riſe without any covering, but they will be later in flowering than thoſe forwarded as above. In either method ſow it moderately thin, either in ſmall drills two inches aſunder, covering it the third of an inch deep, or ſcatter it on the ſurface, and cover it that depth: the plants will riſe in a fortnight or leſs, giving occaſional waterings, and about the middle or latter end of May, or when the plants are about five or ſix inches high, take advantage of ſhowery weather, and plant them out ſingly in the different parts of the borders or fronts of ſhrubberies, in the places where they are to flower, at ſix, eight, or ten feet diſtance, and, if dry weather ſucceed, give a few waterings the firſt week or fortnight.

If you are curious to cultivate only the fine doubles, you may, at the time of planting out, ſet two or three plants together, in patches the above diſtance, and when they ſhew flower, to determine the ſorts, may clear away the worſt, leaving only one of the beſt doubles in each patch.

When deſigned to have a ſhew of the fineſt doubles in pots, they may be tranſplanted therein as ſoon as they are diſcoverable by their bloom, for they will readily tranſplant with balls.

By cuttings or ſlips. This is practiſed only for the propagation of the fine doubles for an early bloom the following ſummer, and the beſt time to perform it is September, or early in October. Cut or ſlip off a quantity of the robuſt ſide-ſhoots, from three to ſix inches long, without flowers; diveſt them of the lower leaves, and plant many of them together in large pots within an inch or two of their tops, and two or three inches apart; give ſome water, and place them in the ſhade during the hot weather, and by the end of October they will be rooted, when remove the pots either into a green-houſe or garden-frame for the winter, but the latter is the moſt eligible, where they may enjoy the full air in mild weather, and have occaſional ſhelter from froſt; and in April tranſplant them ſingly into the borders, and ſome in pots, to move occaſionally to ornament any particular compartment.

The plants thus raiſed will flower a month or ſix weeks ſooner the ſucceeding ſummer, than thoſe raiſed in the ſpring from ſeed.

It is however proper always to raiſe a quantity of ſeedlings annually, as before directed, ſo propagating by cuttings from the beſt doubles of theſe every autumn, for an early bloom the following ſummer, becauſe, by continuing to propagate by cuttings always from the ſame plants, the flowers would degenerate ſmall, leſs numerous, and at laſt becomes barren.

To ſave ſeed from theſe varieties, let it always be from the fulleſt doubles, which, as well as the ſingles, ripen it abundantly in September.

*Propagation of the Perennials.*

The three hardy perennial ſpecies, which are the ſecond, third, and fourth ſorts, may be propagated plentifully, by dividing their roots any time in open weather from October to March. They may likewiſe be raiſed by ſeed ſown in a bed of common earth in March, and raked in lightly; the plants will come up in April or May, and in June or July prick them a foot diſtance in a nurſery-bed to remain till October, then tranſplant them into the borders.

*Propagation of the Shrubby Sorts.*

The two ſhrubby ſorts are eaſily propagated by cuttings planted in pots of rich earth any time from April till July, giving occaſional ſhade and water, and by September will be rooted and fit to tranſplant in ſeparate pots.

CHRYSOCOMA, Goldy-locks, or *Coma Aurea.*

This genus retains herbaceous flowery perennials for the borders, and ſhrubby ornamental plants for the green-houſe, all of erect growth, from one to two feet high, ornamented with narrow leaves, and compound floſcular flowers.

Claſs and order, *Sygeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a compound flower in an imbricated cup of many narrow ſharp-pointed ſcales. COROLLA, compoſed of many floſcular, hermaphrodite, funnel-ſhaped florets, five-parted at the brim. STAMINA, five filaments, and cylindrical antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and two depreſſed ſtigmas. PERICARPIUM, none. SEMINA, a ſingle ſeed, crowned with down, to each floret.

The firſt ſpecies is an herbaceous, fibrous-rooted, very-flowery perennial.

[1]CHRYSOCOMA *Linoſyris.*

*Linoſyris, or German Goldy-locks.*] Chryſocoma with upright, round, robuſt, annual ſtalks, a foot and half high, garniſhed with many long, narrow, ſmooth leaves, and the upper parts dividing into many foot-ſtalks, each ſupporting a head of bright yellow flowers, the whole forming a ſort of umbel, appearing in July, and ripen ſeeds in autumn.

The two following are dwarf ſhrubs of the green-houſe.

[2]CHRYSOCOMA, *Coma Aurea.*

*Shrubby Coma Aurea, or Greater African Goldy-locks.*] Chryſocoma with a ſhrubby ſtem, divided into a ſlender branchy head two feet high, garniſhed with numerous, narrow, running leaves, each having a leafy appendage detached from the back part along the ſtalk, and pale yellow flowers on ſlender naked foot-ſtalks from the ends of the branches, all ſummer and autumn.

[3]CHRYSOCOMA *Cernua.*

*Shrubby Nodding Goldy-locks.*] Chryſocoma with a ſhrubby ſtalk, divided into a branchy head, a foot and half high, garniſhed with ſhort, narrow, hairy leaves, and pale yellow flowers, nodding on one ſide, appearing from the beginning of ſummer till autumn.

The firſt ſpecies, *German Goldy-locks*, flowers very ornamentally about ſix weeks, and ſucceeds in any of the compartments of the pleaſure-ground; its propagation is by dividing the roots any time in open weather from September till March, or it may be raiſed from ſeed in a bed of light earth in March or April.

The two ſhrubby ſorts muſt be kept in pots, and placed in a green-houſe in winter.

They are eaſily propagated by cuttings, in pots of light rich earth in ſpring or ſummer, which, if plunged in a little heat, or cloſely covered with a hand-glaſs about a month, they will readily grow.

CICHORIUM, Succory, or Endive, *(Endivia.)*

This genus furniſhes but one uſeful ſpecies, an herbaceous eſculent of the kitchen-garden, valuable both as a ſallad and a culinary herb, of which there are three eminent varieties.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a compound flower, having a calyculated, imbricated, permanent, general cup. COROLLA, many hermaphrodite, plane, tongue-ſhaped, five-parted florets, placed in a circle. STAMINA, five filaments, and cylindric, pentagonous antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and two revolute ſtigma. PERICARPIUM, none. SEMINA, a ſingle ſeed to each floret, lodged in the calix.

There are three ſpecies in the whole; the Wild Succory of the fields—the Prickly Succory of Sicily—and the cultivated Succory or Endive of our gardens; but the two former have no merit as garden-plants.

The Succory of our gardens is,

CICHORIUM *Endivia.*

*Endive, or Garden Succory.*] Cichorium with a ſpindle-ſhaped fibrey root, crowned by a compact cluſter of numerous, oblong, ſpread-

ing

ing leaves, close to the ground, from about six to ten or twelve inches long, near half as broad, in some sorts fringed and curled, others plane and entire, and in the centre an upright branchy seed-stalk a yard high, garnished with small leaves, and solitary blue flowers, succeeded by plenty of seed.

Varieties are,

*Green Curled Endive*——hath numerous, green, finely fringed, and curled leaves, forming a circular cluster close to the ground twelve or fifteen inches diameter; the centre leaves many, very closely placed, and grow to a large, compact, finely-blanched, white heart. This is considerably the finest variety of Endive for general culture, both for sallads and culinary purposes, and is the hardiest to stand the winter. But the great article is, to have the true sort; for some have long, irregular, thinly-placed leaves, very little curled, and the heart open and loose; therefore, in saving seed, be particular in marking the fullest-leaved, most curly, regular, bushy plants, that bottom well, and have the heart perfectly full, close, and white.

*White Curled Endive*——hath numerous, white, very fringy, curled leaves, in a circular cluster close to the ground, ten or twelve inches diameter, very full and close in the heart.

*Broad-leafed Batavia Endive*—hath long, broad, plane, entire leaves, of a whitish-green colour, thick and crisp like cos-lettuce; but is more proper for culinary uses than sallads, nor is it so hardy to stand the winter as the former varieties; so should be cultivated only for autumn service, i. e. to use in August, September, October, and November.

All the varieties may be considered both as annuals and biennials. Considered as annuals, that if sown early in spring, or even any time before the beginning of June, the plants very commonly fly up to seed the same summer, in their minor, or half-grown state, and perish in autumn. As biennials, that if sown in June or July, the plants acquire perfection in autumn, continue till the spring following, then shoot up stalks for flower and seed, and soon after perish; so, at most, they are never more than biennial.

It is the inner leaves of all the varieties that are the useful parts, which, when blanched white, to render them crisp and tender, and to reduce them from a naturally strong, to an agreeable bitter taste, are then fit for use.

They are valued chiefly as principal furniture for autumn and winter sallads, and for some culinary uses; and their principal season of perfection is, from the latter end of August until Christmas, or longer, according to the temperature of the season; though the curled kinds generally resists the frost of our ordinary winters, and remain in tolerable perfection till March or April.

*Propagation and Culture.*

The propagation of each variety is by seed annually in an open spot of ground, from which the plants are to be transplanted a foot distance, in open beds or borders, to remain to grow to full size, when their leaves are to be tied together, to promote their blanching white.

The principal season for sowing these seeds is from the beginning of June to the end of July; and to have a regular supply of plants, it is proper to perform three different sowings at about three weeks or a month's interval, observing, that if sown before the first week in June, the plants are apt to run to seed the same year without acquiring perfection; and, if sown later than July, they have not time enough to grow to any tolerable size before the approach of winter: however, where the plants are required as early as possible, you may perform an earlier sowing, but the earliest should never be before the middle of May, and even that sowing is apt to fly up soon to seed, so must never depend on this sowing for a main crop; therefore, for the general autumn, winter, and spring crops, I advise the first sowing to be in the first week in June, the next in the last week in the same month, and the third and last about the fifteenth or twentieth of July; and each of these sowings will afford two or three different drawings or transplantings; for it is eligible to make five or six plantations at least, at different intervals, whereby a regular succession of good Endive will be obtained from August until April.

All the sowings should be performed in an open exposure, and the richer the ground the better, which, after being dug, form into a bed or beds four feet wide; directly sow the seed by broad-cast moderately thin, and tread and rake it in with a large rake.

The plants will come up in ten or twelve days, when, if the weather is dry, give occasional waterings; keep them clean from weeds, and where they rise in clusters, thin them

them to two inches diſtance, that they may not draw each other weak, and, when about a month old, tranſplant the largeſt in the following manner.

When the plants of each ſowing are from three to four or five inches high, they are then of a proper ſize for planting out, which ſhould be at once in the place where they are finally to remain; they ſhould be allowed a ſpot of as rich ground as you can afford, and an open expoſure is moſt eligible for the main crops that are planted out in June, July, and Auguſt; but for thoſe intended principally for ſpring ſervice, which are planted out in September, ſhould be ſet near the ſhelter of a South wall or hedge. At each time of planting chuſe moiſt weather, if poſſible, and let the ground be then neatly dug one ſpade deep; divide it into four feet wide beds, and rake the ſurface ſmooth; then draw out a quantity of the ſtouteſt plants from the ſeed-bed, with their roots as entire as you can, and if the plants have run up with long leaves, trim their ſtraggling tops all of equal length, then plant them by line and dibble four rows in each bed, and a foot diſtance in the rows; and that the plants may have the more room to ſpread, ſet them in the quincunx order, (ſee QUINCUNX) finiſhing the work with a good watering, unleſs the weather is very ſhowery, when you may ſpare yourſelf that trouble, though, at any rate, a little water at planting ſettles the earth cloſe to their roots, and is of much advantage; and if the weather is dry, the waterings ſhould be repeated every other day for a week, or till the plants have taken root.

In this manner it is adviſeable to make a freſh plantation every fortnight, from June to the middle of September, by which practice you will obtain a regular ſucceſſion of Endive in due perfection from Auguſt till the following ſpring, proper either for family ſervice, or for market.

When there is a neceſſity of planting any out in very dry weather, it is proper to draw flat ſhallow drills a foot diſtance; ſo ſet the plants therein a foot aſunder, that when water is given, the drills will detain it about the plants, and the earth will retain a moiſtneſs longer than the level ground.

As to the general culture of the different crops, keep each plantation clean from weeds, by hoeing between the plants careſully in dry weather; and when the plants are nearly full grown, a quantity of the largeſt ſhould have their leaves tied up for blanching, which is to be repeated in ſucceſſive order, and the following is the directions.

*Method of Blanching the Plants.*

The great excellence in good Endive is to have the inner parts of the plants finely whitened or blanched, without which they would be tough and diſagreeably bitter; the plants of themſelves naturally incline to whiteneſs in the hearts, but this may be greatly promoted and improved by art, when the plants are arrived at full growth. Different methods are practiſed, ſuch as tying the leaves of each plant up cloſe together; taking up the plants, and replanting them directly almoſt to their tops in ridges of dry earth; laying boards or tiles flat-ways on the plants; but this latter is the moſt unnatural and ineffectual of all the methods; and the beſt of all is the tying up the leaves, which in a fortnight will be blanched. The proper period to begin this work is, when the plants are nearly full grown; that is, when they are ſo much advanced, that the leaves of the different plants interfere, and their hearts are full and buſhy; but they are not all to be tied up at once, only a due ſupply of the largeſt and forwardeſt plants once every ten or twelve days, according to the demand either for private uſe or market. Dry weather, if poſſible, ought to be choſen for this work, and when the plants themſelves are alſo dry, then, having ſome ſtrong baſs ſtrings, or oſier twigs, gather all the leaves of each plant up regularly, diveſting them of damaged ones, and with theſe materials tye them cloſe together a little above the middle, or within about three inches of the top, being careful not to bind them too ſtraight.

In fifteen or eighteen days ſome of the forwardeſt plants of each tying will be tolerably well blanched, but in about three weeks they will be in excellent order.

To blanch them in ridges of earth. This is ſometimes practiſed in winter, when there is danger of ſevere froſt ſetting in; for by burying the plants almoſt to their tops, they are more out of the power of froſt. In November or December, or when you apprehend hard weather is approaching, let a warm lying piece of light dry ground be trenched up in one or more ſharp ridges two or three feet wide at bottom, and near as much in height, and ſide-ways to the ſun, making the ſides as ſteep as poſſible, that wet may run quickly

quickly off; then, in a dry day, take up a quantity of your full-grown plants, with their roots entire, diveſting them of damaged leaves, and then gathering each plant cloſe in your hand, place them horizontally in the ſunny ſide of the ridge of earth almoſt to their tops, and about ſix or eight inches each way diſtant, which is room enough, as it is only juſt to blanch them; here they will take root and blanch effectually, obſerving, that when ſevere froſty weather prevails, it would be of much advantage to cover the ridge with dry long litter, to ſecure the plants, and prevent the earth from being frozen hard, that they may be readily taken up when wanted.

In very ſevere weather, it would alſo be of much advantage to beſtow covering on ſome of the beſt plants in the full ground; and where there is only a few for family uſe, it may be eaſily effected either by mats or dry long litter, being careful to remove the covering as ſoon as the weather alters.

*Saving the Seed.*

Particular attention is neceſſary in ſaving Endive-ſeed, to mark for that purpoſe ſome of the very beſt ſorts of each variety, for the plants are very ſubject to degeneracy.

Therefore, in October or November, place ſome ſticks as marks to ſome of the moſt ſtocky full plants, which may either remain, or in March be tranſplanted into a ſheltered ſunny ſituation, in rows two feet diſtance, and eighteen inches aſunder in the lines; or if planted in a ſingle row againſt a ſouth wall, pale, or hedge, it would be convenient for ſupporting their ſeed-ſtems. They will ſhoot up their ſtems in April or May, which early in June will require ſupport, either of a ſtout ſtake to each plant, or, if ſituated againſt a wall, &c the ſtems may be faſtened thereto by a line of packthread; the ſeed will ripen in July and Auguſt, having attention to cut off the branches from time to time as the ſeed acquires maturity, which, according as it is properly dried in the ſun, beat out on cloths, and put it up for uſe in bags or boxes.

CIRRHUS, a Claſper or Tendril; that fine ſpiral ſtring iſſuing from the branches, foot-ſtalks, and leaves, of many ſorts of trailing and climbing plants, by which they faſten themſelves to other bodies for ſupport.

A Claſper is one of the ſeven ſpecies of *Fulcra*, or props or ſupports of plants. See FULCRA.

Claſpers are of ſingular uſe to moſt of the trailing and climbing tribe, in aſſiſting them to climb and ſupport themſelves, as they moſtly have long, ſlender, fragile ſtalks and branches, which would trail on the ground, and be liable to be diſplaced, and frequent breakings, unleſs by means of their tendrils, which either twine round any thing in their neighbourhood; as, for inſtance, thoſe of peas twine round ſticks or buſhes, and thereby mount their ſtalks and branches ſeven feet high; and thoſe alſo of the vine and paſſion-flower, and of many others, twine round their own, or neighbouring branches, or any other contiguous ſupport; and ſome climbers emit Claſpers, which plant themſelves like roots in the adjacent walls, or the bark of neighbouring trees, as exemplified in ivy, the *Bignonia Radicans*, the *Solanum Dulcamara*, and many other ſorts; their ſtalks thereby mounting thirty or forty feet high. See CLIMBER.

As to the ſituation of Claſpers on the reſpective plants, they ſometimes are placed oppoſite to the leaves, as in the vine; ſometimes at the ſide of the foot-ſtalk of the leaf, as in the paſſion-flower; and ſometimes proceed from the leaves themſelves, as in the pea; and are either ſimple, or of one ſtring, as in moſt Cirrhus plants; or compound, i. e. of two or more, as in *Lathyrus Latifolius*, broad-leafed or common everlaſting pea.

CISTUS, Rock-Roſe, *(Ciſtus)*.

This genus furniſhes beautiful ſhrubby evergreens for the pleaſure ground and greenhouſe, adorned with oblong, ſpear-ſhaped leaves, and numerous quinquepetalous white and purple flowers.

Claſs and order, *Polyandria Monogynia*.

*Characters.*] CALIX, five roundiſh concave leaves. COROLLA, five roundiſh, large, plane, patent petals. STAMINA, numerous capillary filaments, and roundiſh antheræ. PISTILLUM, a roundiſh germen, ſingle ſtyle, and plane orbicular ſtigma. PERICARPIUM, an oval, covered capſule, and numerous, ſmall, roundiſh ſeeds.

There are numerous ſpecies of *Ciſtus*, the greater part of which are of the ſhrub kind, and there are ſome of herbaceous growth; but thoſe that merit notice in gardening are moſtly ſhrubby evergreens, very floriferous and ornamental.

The ſpecies of our gardens are,

1 CISTUS *Populifolius*.

*Poplar-leafed Ciſtus.*] Ciſtus with a ſhrubby

ſtem, branching each way five or ſix feet high, garniſhed with large, heart-ſhaped, pointed, ſmooth leaves, having foot-ſtalks; and at the ſides and ends of the branches numerous large white flowers.

[2]CISTUS *Ladaniferus.*

*Ladanum-bearing, or Spaniſh Gum Ciſtus.*] Ciſtus with a ſhrubby ſtrong ſtem, branching from the bottom upward, forming a buſhy head five or ſix feet high, adorned with ſpear-ſhaped leaves, ſmooth and green on the upper ſide, whitiſh and veined below, ſtanding on ſhort foot ſtalks joining at their baſe round the branch like a ſheath; and numerous large purpliſh flowers at the ſides and ends of the branches.

*Varieties.*] *Willow-leafed Ladaniferous Ciſtus* —having narrow pear-ſhaped leaves, and large white flowers, having a purple ſpot at the baſe of each petal—and with entire white flowers.

[3]CISTUS *Albidus.*

*White Downy-leafed Ciſtus.*] Ciſtus with a ſhrubby ſtem, branching erectly from the bottom five or ſix feet high, having woolly branches, garniſhed with oval-ſpear-ſhaped, trinervous, white, downy, cloſe-ſitting leaves; and all the branches terminated by large bright purple flowers.

[4]CISTUS *Creticum.*

*Cretan Ladaniferous Ciſtus* ] Ciſtus with a ſhrubby ſtem, branching laterally three or four feet high; oval-ſpatulated, enervous, rough leaves, on ſhort foot-ſtalks; and deep purple flowers, on footſtalks at the ends of the branches.

[5]CISTUS *Monſpelienſis.*

*Montpelier Gum-Ciſtus.*] Ciſtus with a ſhrubby ſtem, branching laterally from the bottom upward, three or four feet high; ſpear-ſhaped, trinervous, hairy, cloſe-ſitting, dark-green leaves; and from the ends of the branches, long naked foot-ſtalks, ſuſtaining many large white flowers.

[6]CISTUS *Piloſus*

*Hairy Round-leafed Ciſtus.*] Ciſtus with a ſhrubby, ſtrong, rough ſtem, branching to a large buſhy head, a yard or four feet high, garniſhed with oval-roundiſh hairy leaves, growing oppoſite on ſhort foot-ſtalks; and many large purple flowers from the ſides and ends of the branches.

[7]CISTUS *Incanus.*

*Hoary-leafed Ciſtus.*] Ciſtus with a ſhrubby ſtem, branching to a large buſhy, head three or four feet high; ſpatulate-ſhaped, hoary, rough, cloſe-ſitting leaves, the lower ones oval and united at their baſe, the upper ones ſpear-ſhaped and diſtinct; and all the branches and ſhoots terminated by large purple flowers.

*Varieties.*] Long-leaved Hoary Ciſtus —— Roundiſh-leaved Hoary Ciſtus—Large Hoary-leaved Ciſtus.

[8]CISTUS *Criſpus.*

*Waved Curled-leafed Ciſtus.*] Ciſtus with a ſhrubby ſtem, diffuſing horizontal branches, forming a ſpreading head a yard or more high; ſpear-ſhaped, waved, bending, hairy leaves, in pairs oppoſite; and from the axillas of the leaves, many white flowers on naked foot-ſtalks.

[9]CISTUS *Salvifolius.*

*Sage-leafed Ciſtus.*] Ciſtus with a ſhrubby, ſlender, ſmooth ſtem, a yard high, branching horizontally and ſpreading, garniſhed with ſmall, oval, hairy, petiolated leaves; and from their axillas, white flowers on long naked foot-ſtalks.

[10]CISTUS *Laurifolius.*

*Bay-leafed Gum-Ciſtus.*] Ciſtus with a ſhrubby ſtrong ſtem, branching erectly, forming a head five or ſix feet high; oblong oval, trinervous, petiolated leaves, ſmooth and green above, their foot-ſtalks joined at the baſe; and from the ſides and ends of the branches, large white flowers on branching foot-ſtalks.

[11]CISTUS *Halimifolius.*

*Sea-Purſlane-leafed Ciſtus* ] Ciſtus with a ſhrubby ſtem, branching erectly from the bottom upward, forming a buſhy head four feet high, adorned with oblong-oval, very white, hoary leaves, in pairs oppoſite; and at the ſides and ends of the branches, very long, branching, naked foot-ſtalks, ſupporting large, bright, yellow flowers.

*Varieties.*] Broad-leafed *Halimifolius* Ciſtus —Narrow-leafed *Halimifolius* Ciſtus.

The flowers of all theſe ſpecies are compoſed each of five large, round, ſpreading petals, ſee the *Characters*; and are extremely numerous on the plants, appearing principally in May, June, and July; and many of the ſorts afford plenty of ripe ſeeds.

The leaves of theſe ſhrubs exhibit great variety in different ſpecies, being of very different ſhapes, ſizes, and of many different ſhades of green and white, and which, in moſt of the ſpecies, are covered with a clammy or gummy ſubſtance, of a ſtrong balſamic ſcent, of which is prepared the ladanum of the ſhops; hence ſeveral of the ſpecies are titled Ladaniferous, or Gum-bearing Ciſtus, which they

they impart more abundantly in the ſummer months, and is collected for uſe in the countries where the ſhrubs naturally grow.

They are natives principally of the ſouthern parts of Europe, but ſucceed here in the open air the year round.

All the ſpecies are beautiful evergreen ſhrubs, generally very branchy quite from the bottom, forming diffuſed heads, and are all very ornamental in gardens, not only as evergreens, effecting a fine variety at all ſeaſons, with their leaves of different figures, ſizes, and ſhades of green and white, but alſo as firſt-rate flowering ſhrubs, being very profuſe in moſt elegant flowers, which, though of only one day's duration, there is a daily ſucceſſion of great numbers of new ones, continued a month or ſix weeks on the ſame plant; and when there are different ſpecies, they will exhibit a conſtant bloom near three months, and all the ſorts begin flowering when little more than a foot high.

They are all hardy enough to proſper in the full ground in any dry ſoil, and if they have a ſheltered ſituation it will be an advantage, as, in open expoſures, they are rather ſubject to injury from very ſevere froſt; for which reaſon, where there is green-houſe room, a plant or two of each ſort may alſo be potted to have ſhelter in winter, by way of reſerve, eſpecially while young.

The more tender ſorts are the *Ceſtus Laurifolius*, and *Halimifolius*.

Their ſituation in ſhrubbery works ſhould be towards the front of the clumps and other compartments, in aſſemblage with the choiceſt ſhrubs of ſimilar growth, diſperſing them ſo as to effect variety, and to have ſhelter of the other plants; but by no means croud them.

Let all the ſorts aſſume their own natural growth, that is, never to ſhear or trim them cloſe, but only juſt ſhorten or retrench with a knife any particular rambling branch.

*Propagation.*

All the ſorts of *Ciſtus* are raiſed by ſeeds and cuttings, either in common earth, or in a hot bed.

The ſeeds produce the handſomeſt plants, and the time for ſowing is March. Theſe ſeeds may either be ſown in a warm border near half an inch deep, and the plants will come up in ſix weeks; or, to bring them more forward, the ſeed may be ſown in pots, and plunged in a moderate hot-bed, and the plants will appear in leſs than a month, when they muſt be afforded the full air in mild weather; and frequent waterings is alſo neceſſary to the plants raiſed in either method, as well as occaſional ſhade from the ſcorching ſun while young. The plants will grow near a foot high the ſame year; but when they are an inch or two high, ſome may be pricked out to thin them, planting ſome ſeparately in ſmall pots, others in a rich border, giving occaſional ſhade and water during ſummer, and in October move the potted plants to a frame to have ſhelter from froſt; all thoſe in the full ground ſhould alſo be ſhielded in froſty weather with mats. In ſpring, thoſe left in the ſeed-bed ſhould be planted out, and the potted plants ſhifted into larger pots, in which they may be continued, to have ſhelter another winter; and in ſpring following tranſplant moſt of them into the nurſery, or where they are always to remain.

By cuttings: their propagation this way may be performed any time from May till Auguſt. Chuſe cuttings five or ſix inches long, and plant them in a bed of rich earth, giving occaſional ſhade and water; they will be rooted, and fit to tranſplant into ſeparate pots in eight or ten weeks, managing them as the ſeedlings.

If a quantity of cuttings are planted in pots in ſpring, and plunged in heat, it will bring them much forwarder.

CITHAREXYLON, Fiddle-wood, or Fidelle-wood.

It furniſhes two beautiful evergreen ſhrubs for the ſtove, adorned with large oblong leaves, and bunches of funnel-ſhaped, monopetalous, white flowers.

Claſs and order, *Didynamia Angroſpermia.*

*Characters.*] CALIX, monophyllous, and indented into five parts. COROLLA, one funnel-ſhaped petal, five-parted and ſpreading at top. STAMINA, two long and two ſhort filaments, and didymous antheræ PISTILLUM, a roundiſh germen, ſlender ſtyle, and headed ſtigma. PERICARPIUM, a roundiſh unilocular berry, and two ſeeds.

The ſpecies are,

[1]CITHAREXYLON *Cinereum.*

*Cinereous Citharexylon.*] Citharexylon with an upright robuſt ſtem, taper branches, and cinereous bark; oblong-oval firm leaves, placed oppoſite; and at the ſides and ends of the branches looſe ſpikes of white flowers.

[2]CITHAREXYLON *Caudatum.*

*Caudated Citharexylon* ] Citharexylon with an upright robuſt ſtem, divided into many

taper branches; oboval oppoſite leaves; and long ſpikes of white flowers at the ends of the branches.

They grow to large trees in America, but appear like ſhrubs in this country, where they muſt be always retained in pots, and continued in the ſtove, except about two months in the heat of ſummer.

Both the ſpecies are propagated by ſeed procured from America, ſowing it half an inch deep in pots of rich earth, and plunge them in a bark-bed.

They may alſo be propagated by cuttings planted in ſpring in pots of rich earth, and plunged in the bark-bed.

CITRUS, the Citron-tree, including the *Limon* or Lemon-tree, and *Aurantium*, the Orange-tree.

Former authors on gardening and botany conſidered the Citron, Lemon, and Orange, as three diſtinct genera, and treated of them accordingly; but their generical characters being the ſame, Linnæus joins them all as ſpecies and varieties of the genus *Citrus*.

They are all moſt beautiful evergreens of the tree kind, natives of diſtant warm climates, ſo are retained here as green-houſe plants.

Claſs and order, *Polyadelphia Icoſandria*.

*Characters.*] CALIX is monophyllous and indented in five parts. COROLLA, five oblong, plane, ſpreading petals. STAMINA, twenty filaments, united below into ſeveral bodies, and oblong antheræ. PISTILLUM, a roundiſh germen, cylindric ſtyle, and globular ſtigma. PERICARPIUM, a large, baccaceous, oval, fleſhy-rinded fruit, full of ſucculent pulp, and divided internally into nine cells, each containing two oval hard ſeeds or kernels.

There are but three ſpecies, each of which admits of many varieties in reſpect to the properties of their reſpective fruit, though, according to Linnæus, the Lemon is only a variety of the Citron; there is indeed but little difference in their general habit, only that the Citron is rather the ſtrongeſt ſhooter, the leaves and fruit larger; and the leaves of both theſe ſorts are large and thick, and having linear foot-ſtalks, are diſtinguiſhable from the Orange, whoſe leaves are rather ſmaller, and of thinner ſubſtance, and have winged foot-ſtalks, *(petiolus alata)* i. e. a ſort of leafy appendage at the baſe of each leaf.

The ſpecies are,

[1]CITRUS *Medica.*

*The Citron-tree.*] Citrus with an upright ſmooth trunk, divided at top into a branchy, ſtrong-ſhooting, full head, from about five to fifteen feet high, adorned with large, oval-ſpear-ſhaped, thick leaves, having linear foot-ſtalks, and numerous flowers from the ſides of the branches, ſucceeded by very large, oblong oval, pointed, rough-rinded fruit.

There are many varieties; the fruit is held to be a ſovereign remedy againſt poiſon, and is an excellent ſweetmeat, for which it is principally eſteemed, being rarely eaten raw.

*The Varieties of note are*] Citron-tree with ſour fruit—with ſweet fruit—with warted fruit—with long fruit—with recurved fruit—with bloatched leaves.

[2]CITRUS *Limon.*

*The Lemon tree.*] Citrus with an upright ſmooth trunk, divided upward into a branchy regular head, from five to twelve or fifteen feet high; large, oval, ſpear-ſhaped, pointed, ſlightly-ſawed leaves, on linear foot-ſtalks; and many flowers from the ſides of the branches, ſucceeded by large oval fruit, prominent at the top.

*Varieties of note are*] Lemon-tree with ſour fruit—with ſweetiſh fruit—with very large fruit, called Imperial Lemon—with pear-ſhaped fruit—with furrowed fruit——with cluſtered fruit—with childing fruit—with whitiſh fruit—with tricolor-ſtriped fruit—with gold-ſtriped leaves—with ſilver-ſtriped leaves—with double flowers.

*The Lima, or Small American Lemon, called Lime*—the tree having ſomewhat ſpinous branches, oval entire leaves, and very ſmall ſour fruit—and with ſweet fruit.

[3]CITRUS *Aurantium.*

*Aurantium, or Orange-tree.*] Citrus with an upright trunk, dividing upward into a branchy regular head, from five to ten or twelve feet high; oval, ſpear-ſhaped, entire leaves, having winged foot-ſtalks, and numerous white flowers at the ſides of the branches, ſucceeded by globular fruit, compreſſed at both ends.

Varieties of moſt note are,

*Seville Orange*—A large, rough-rinded, ſour fruit, of excellent quality for œconomical uſes. The tree is a handſome grower, and rather the hardieſt of all the Orange tribe, as in this country it ſhoots freely, produces large and beautiful leaves, and flowers ſtronger and more abundantly, and generally bears a greater quantity of fruit, than any other ſort, and arrives to greater perfection; ſo theſe trees ſhould be the moſt cultivated.

*China Orange*—The tree has moderate-ſized leaves,

leaves, and a ſmooth, thin-rinded, ſweet fruit, of which are ſeveral varieties in warm countries, where they grow in the open ground.

*Great Shaddock-Orange, or Pumplemoes*—The tree a large grower and ſtrong ſhooter, with large, thick, ſomewhat ſerrated leaves, and very large fruit, having a reddiſh pulp; derives the term *Shaddock* from one of that name, who firſt brought it from the Eaſt-Indies.

*Horned Orange*—A common-ſized tree, producing fruit which divide, and the rind runs out into diviſions like horns.

*Hermaphrodite Orange*—A common ſized tree, producing fruit partly like an Orange, and partly Citron ſhaped.

*Willow-leafed Orange-tree*—having narrow, ſpear-ſhaped leaves—Striped Willow-leafed Orange.

*Dwarf Orange-tree, or Nutmeg-Orange*—having a low ſtem, and ſmall buſhy head, growing two or three feet high; ſmall oval leaves in cluſters; and numerous flowers in cluſters, covering the branches, ſucceeded by very ſmall fruit.

Other varieties are—Silver ſtriped-leaved Orange-Tree—with gold-ſtriped leaves——with curled leaves—with double flowers.

Of each of the above three ſpecies, there are many more leſs material varieties than are here noticed, in the countries where they grow in the open ground; and the varieties, like our apples and pears, may be multiplied by ſeed without end, but, like other fruit ſo raiſed, it is probable there may not be one in a hundred worth notice; ſo that the approved ſorts can only be continued with certainty by budding.

The flowers of all the ſpecies and varieties are formed each of five ſpreading petals, appearing here principally in May or June, and the fruit continue ſetting in June and July, and ripen the year following.

All the ſorts are elegant evergreens of the tree kind, obtaining in England from about five to eight or ten feet ſtature, forming full and handſome heads, cloſely garniſhed with beautiful large leaves the year round, and a profuſion of ſweet flowers, in ſpring and early in ſummer, which, even in this country, are often ſucceeded by abundance of fruit, ſometimes arriving to tolerable perfection; but the chief merit of theſe trees in England is for ornament, which conſiſts not only in their beautiful foliage, but alſo in the flowers and fruit, and have this peculiar merit, as to exhibit bloſſom, green fruit in different ſtages of growth, and full-grown ripe yellow fruit, all at the ſame time, which, together with their large ſhining-green leaves, effects one of the moſt beautiful contraſts of our gardens, which renders all the ſorts very deſireable furniture for the green-houſe collection; but the Oranges and Lemons are rather the hardieſt, and generally more fruitful here in England than the Citron, and the Seville-Orange moſt of all, which is the only ſort of Orange to be depended on for any conſiderable quantity of flowers and fruit; the tree being hardieſt, retains its fruit in winter better than moſt of the other varieties.

Theſe trees are all natives originally of India, but have been long retained in our gardens as green-houſe plants; and in the ſouthern parts of Europe, as Portugal, Spain, and Italy, they grow in the open ground like our apple and pear-trees, and from which countries vaſt quantities of the fruit are imported hither annually; but here in England the trees muſt always be continued in pots or tubs, to be houſed in winter.

They all ſucceed in the open air from the beginning of June until the middle or latter-end of October, and the reſt of the year muſt have the ſhelter of a green-houſe, and they proſper in any good garden-mould. See their *General Culture*.

Trees of all theſe ſorts are retained in moſt of the nurſeries for ſale, where ſuch perſons as are in haſte to have a collection may be furniſhed; the prices from five ſhillings to as many guineas, according to the ſorts, ſizes, and properties.

As to the method of raiſing and management of all the ſorts, ſee the following different articles of their *Propagation*, and that of their *General Culture*.

*Their Propagation by Seed for Varieties, and to raiſe Stocks to bud upon, &c.*

All the varieties of this genus were originally obtained from ſeed; but the only certain method to continue the reſpective approved varieties is by budding or inarching them on ſtocks of their own kind, raiſed from ſeed to a proper ſize. See their *Propagation by Budding, &c.*

By ſeeds, i. e. the kernels of the fruit: this method of raiſing theſe trees is rarely practiſed in England, except for ſtocks, on which to bud the different kinds; for although raiſing the trees entirely from ſeed, without budding, is the way to gain new varieties, as obſerved

obſerved of peaches and other fruits, yet out of numbers ſo raiſed, it is probable not a tree of them may produce fruit that poſſeſs any good property, but what will be ſmall, crab-like, and intolerably ſour and harſh; but when any new valuable variety is by this means accidentally obtained, it is continued and multiplied by budding it upon ſtocks, raiſed from the kernels of any of the ſorts of *Citrus*, for they all take upon one another, ſee their *Propagation by Budding*; and by which practice all the above-deſcribed varieties are annually encreaſed in our gardens. As the method therefore of raiſing them entirely from ſeeds, except for ſtocks, is both tedious and uncertain; that is, it is tedious, becauſe they are often many years before they arrive to a bearing ſtate, and uncertain, as, that after all the trouble, they perhaps are neither beautiful in their foliage, flowers, nor fruit, compared with thoſe which are budded with the known and approved kinds; ſo that in this country it is ſcarce worth practiſing, unleſs a few merely for curioſity.

The raiſing them, however, from the kernel, either to form trees for new varieties, or for ſtocks to bud upon, is, in this country, performed the moſt effectually and expeditiouſly by the aid of a hot-bed, and by which means ſtocks may be obtained, of due ſize for budding, in two years; the following is the method of raiſing them.

Early in ſpring procure ſome kernels, which may be had plentifully from rotten fruits, or others that are perfectly ripened, obſerving, that for ſtocks, the Citron, Lemon, and Seville-Orange, as being the freeſt ſhooters, are to be preferred, though the Citron is the ſtrongeſt ſhooter of the three: ſow the kernels in March, in pots of rich light earth half an inch deep, and plunge them in a hot-bed, under frame and glaſſes, of dung or tan, but the latter is preferable, giving air, and frequent ſprinklings of water. In two or three weeks the plants will come up, being careful to give air and water, and in ſix weeks, or two months more, they will be advanced four or five inches, or more, in height; obſerving, in the middle or latter end of June, to harden them to the full air, in which let them remain till October, then move them into the green-houſe, to ſtand till ſpring, when, in March or April, proceed to plant them ſingly in ſmall pots (forty-eights), being careful to ſhake them out of the ſeed-pot with their roots entire, and having half filled the other pots with light, rich, loamy compoſt, place one plant in each pot, filling it up over the roots with the ſame ſort of earth, and let them be directly watered, repeating it occaſionally till freſh rooted; afterwards treat them as other woody exotics of the green-houſe, and in a year or two, the largeſt of thoſe deſigned for ſtocks will be fit to bud.

But, to have ſtocks as forward and fine as poſſible for budding, I would adviſe, where convenient, that, as ſoon as they are potted out as above, to plunge them directly in a hot-bed, under a frame and glaſſes, about three or four months, which will draw them up in height with handſome ſtems.

A bark-bed would be the moſt eligible, made either in a glaſs-pit, or to be covered with a deep frame and lights; ſo plunging the pots to their rims in the bed, giving occaſional ſhade in the middle of hot ſunny days, and freſh air daily, by tilting one end of the lights, more or leſs, as you ſhall judge expedient: likewiſe refreſh them frequently with water, and by the middle or end of July the plants will be advanced fifteen or eighteen inches, or near two feet high, obſerving then to harden them by degrees to the full air for the remainder of the ſummer; and, by being thus forwarded, thoſe deſigned for ſtocks will be in excellent order for budding the year following. See their *Propagation by Budding*.

But theſe ſeedlings may ſtill be more forwarded, and a year or two's growth may be gained by forcing them, as above, the firſt ſeaſon. This is effected by pricking out the ſeedlings the firſt year they come up, when two or three inches high, in ſmall pots, as above, to be plunged either in a bark-bed, or even in a dung hot-bed, covered with old tan eight or ten inches deep for the reception of the pots, made in a bark-pit, or, at leaſt, under ſome deep frame and glaſs, as before directed; the plants are then to be potted ſingly, according to the former directions, and plunged in the hot-bed, indulging them, as before adviſed, with occaſional ſhade, freſh air, and water; and by the middle or end of July, they will have advanced to twelve or fifteen inches, or, perhaps, to a foot and half, or near two feet in height; they muſt then be gradually hardened to the full air, by raiſing the lights more and more every day, leaving them alſo up on nights, and at laſt take them quite off in a cloudy calm day; ſo let the plants remain fully expoſed till October, then move them into the green-houſe for the winter,

and

and many of them will be in due order to receive the buds next Auguſt; and the following is the method.

*Propagation by Budding.*

The operation of budding all the ſorts of *Citrus* is performed in Auguſt upon ſtocks of their own kinds, for all the ſpecies and varieties of this genus take freely upon one another, and the budding or inoculation is performed in the common way. See INOCULATION.

But, as already noticed, the Citron, Lemon, and Seville-Orange, being the freeſt ſhooters, are generally preferred for ſtocks; and thoſe of all the ſorts are raiſed from the kernel, as above directed in the *Propagation by Seed*, which, when from about fifteen to eighteen inches, or two feet high, and about as big as a middling gooſe-quill, or a little more or leſs, are of due ſize for budding.

As to the buds for budding them, obſerve to procure cuttings only from bearing free-ſhooting trees, of the ſorts you would encreaſe; young ſhoots, that are round and plump, muſt be choſen, and from theſe take the buds in the uſual manner, being careful to inſert them in a ſmooth part of the ſtock, at about ſix to ten or fifteen inches from the bottom, one bud in each ſtock, tying them properly with a ligature of baſs. See INOCULATION.

As ſoon as the budding is finiſhed, it is proper to place the plants in their pots in the green-houſe, or in a glaſs-caſe, &c. to defend the buds from wet and drying winds, turning the budded part from the ſun; or, where there is the convenience of a ſpare bark-pit, where the heat of the bark is almoſt exhauſted, may plunge the pots therein two or three weeks, and it will more effectually promote the union of the buds; obſerving, in either department, to admit air freely, by opening the front glaſſes, allowing alſo a ſlight ſhade of mats in the middle of ſcorching ſunny days, and ſupply the pots with water every day or two during the hot weather; in three or four weeks the buds will be united with the ſtocks, when it is proper to looſen the bandage of each bud, that they may have room to ſwell; obſerving, however, that the buds will all remain dormant till ſpring.

After this there is nothing more required this year but due waterings, only obſerving, that in caſe of great rains, it will be proper to retain the plants in the green-houſe for the remainder of the ſummer, and until next ſpring.

In March following, the heads of all the ſtocks muſt be cut off ſlanting cloſe behind the inſertion of the bud; after this operation the buds will ſoon begin to ſpring, and produce each one ſhoot, which probably will obtain from about five or ſix, to eight or ten inches in length the ſame year; but it is proper to obſerve, that if they could have the aid of a bark-bed, there will be a chance of having the buds ſhoot a foot and half, or more, by the end of ſummer; therefore, where there is the convenience of a bark-pit, or glaſs-caſe, or any deep frame, that can be placed on a bark bed, &c. I ſhould adviſe by all means to make uſe of ſuch conveniencies for forwarding the firſt ſhoot of the buds; ſo that as ſoon as the ſtocks are headed, as above directed, plunge the pots in the hot-bed, and let them enjoy the benefit of air and water, in proportion to the temperature of the bed and weather; likewiſe occaſional ſhade when the ſun is very powerful: here they may be continued, with the above care, till the end of July, when ſome of the ſtrongeſt ſhooters will be advanced near two feet high; and it is then proper to begin to inure them by degrees to the full air, to harden them againſt winter, that they may be able to live during that ſeaſon in the green-houſe, to which they muſt be removed in October.

As to their culture, in reſpect to training, you may train each with a ſtem to what moderate height you think proper, though, when they have formed ſtems two or three feet high, I would ſuffer them to branch out towards the top, to form a head, which ſhould be permitted to retain their natural growth, unleſs you ſhall ſee neceſſary to ſhorten any particular ſhoots, that they may throw out laterals, to form a fuller or more regular head; likewiſe to retrench or ſhorten any very irregular or rambling branch.

For their further management, ſee their *General Culture.*

*Propagation by Inarching.*

This method of propagating Citrus-trees was more in practice formerly than ſince the art of budding them has been ſo improved, as to form much handſomer trees. See INARCHING.

When it is however deſigned to propagate by this method any of the ſorts of Citrus, ſtocks muſt be raiſed from ſeed, as before directed,

directed, which, when of due ſize, are to be placed in their pots, upon a ſort of ſtage, or ſome erection convenient to the head of the trees you intend to inarch from, obſerving to fix upon ſome convenient young ſhoots, nearly the ſize of the ſtocks, for the purpoſe of inarching; theſe are to be inarched in the ſtocks, as they grow on the trees, in April or May, one in each ſtock, and by the end of Auguſt following they will be united to the ſtock, and may be ſeparated from the parent tree.

But this method of propagating theſe trees, is rather practiſed by way of curioſity, to raiſe a few trees to a bearing ſtate in haſte, becauſe, by inarching a young bearing branch, furniſhed with fruit, into any of their own ſtocks, in April or May, it will frequently be united by the following Auguſt, and the branch ſo inarched may be ſeparated from its parent plant, and, being firmly attached to the ſtock, it then commences a new tree, bearing fruit, raiſed in the ſhort ſpace of four or five months.

By the ſame rule you may inarch an Orange into the branch of a Citron or Lemon, or all three upon the ſame tree, for the ſake of variety.

But trees raiſed by this method never grow ſo large nor handſome as thoſe raiſed by budding.

### *Of managing the trained Trees brought from abroad.*

If any one is anxious to have a collection of large trained trees of any of the ſorts of *Citrus* as ſoon and as cheap as poſſible, the only way is, to have recourſe to thoſe imported from Italy or Portugal, &c. great quantities of trained trees of all the ſorts being imported hither from thoſe countries every ſpring for ſale; they come over in cheſts, without any earth to their roots, having their roots and heads a little trimmed; they are in ſize commonly from about one inch to two or three diameter in the ſtem; the ſtem from two to four or five feet high; and by aid of a bark-bed they readily take root and grow freely, and form as good trees in two years, as we could raiſe here in fifteen or twenty from ſeed and budding.

They are ſold in the Italian warehouſes in London, the principal one of which has been for many years in the Hay-market, near the bottom, next Pall-mall, from about three ſhillings to a guinea a-piece, according to their ſize, and are generally advertiſed as ſoon as they arrive, which is early in ſpring, and the ſooner the better.

In the choice of theſe trees obſerve, they are commonly budded at ſuch height in the ſtem, as to form heads from about two to four or five feet high; and as they are frequently furniſhed with two buds, one on each ſide of the ſtem, theſe are what we ſhould chuſe, if poſſible, as they will conſequently form the moſt regular heads.

A bark-bed muſt be prepared to ſtrike them, either in a glaſs-caſe, bark-pit, or ſome other ſimilar department, where a bed can be made, either in a ſunk or raiſed pit; preparatory to their planting, place the trees half way or more in tubs of water a day or two, to plump their bark and roots, to prepare them for vegetation; then proceed to planting them, firſt cleaning their roots, and trim them from damaged parts, and all the ſmall dried fibres; likewiſe waſh and clean their ſtems, and trim the branches of the head to half a foot in length; this done, get the earth and pots; let the earth be rich and moderately light, and the pots proportionate to the ſize of the roots of the plants; place one tree in each pot, giving water as ſoon as planted; at the ſame time, it is of utility to wrap a thin hay-band ſlightly round each ſtem, to prevent their outward bark from being parched by the heat of the ſun; then let all the pots be regularly plunged to their rims in the hot-bed, prepared, as above, for their reception.

Here they are to remain three or four months; muſt be frequently, but moderately watered, both at bottom, and over their tops; and as the ſeaſon advances, and the ſun's heat is vehement, it is neceſſary to ſhade the glaſſes a few hours in the middle of ſunny days; obſerving alſo, that when the heads begin to ſhoot freely, do not omit giving air, which muſt be gradually encreaſed, in proportion to the heat of the ſeaſon, and advanced growth of the ſhoots; by the beginning of June the heads will be conſiderably advanced in ſhooting, at which period obſerve, if the ſhoots are but thinly placed, it is eligible to top them, to promote their emitting laterals to form a fuller head; at this time alſo admit air freely, to harden the ſhoots gradually, to prepare the trees for being moved to the full air in the middle or latter-end of July; they ſhould then be placed in a ſituation, defended from boiſterous winds, and the violence of the noon-day ſun, to remain till the beginning of October; then to be placed in the green-houſe for the winter,

and managed as the other trees. See their *General Culture.*

*General Culture of all the Sorts.*

As to the general culture of all theſe trees, whether raiſed in England, or procured from abroad, let it be obſerved, that, as all the three ſpecies and their varieties are ſo nearly alike in their nature, one common method of culture ſerves for the whole; they all proſper in any common rich earth or compoſt, and muſt all be retained always in pots or tubs, for the convenience of moving them to ſhelter of a green-houſe in winter; or the trees may even be planted in the full ground, to be trained either as wall-trees or ſtandards, provided there is a proper frame erected for the ſupport of glaſs lights, to ſhield them in winter, and with flues, to make occaſional fires in ſevere weather.

It is neceſſary to obſerve, that all the ſorts ſucceed in the open air here, only from the latter end of May until the middle or end of October; the reſt of the year require ſhelter of a green-houſe, &c.

In the green-houſe, place the talleſt trees behind, and the loweſt in front; or, where they are all nearly of a height, thoſe behind ſhould be elevated upon ſtands, ſo as their heads may form a ſort of gradual ſlope from the front to the backward row, and, if poſſible, their heads ſhould ſtand clear of each other During their reſidence in the green-houſe, the principal care is to give air and water, and ſecure them from froſt; freſh air muſt be admitted freely every day in all mild calm weather, when not foggy or very wet, by opening the windows leſs or more, from about eight or nine in the morning, till three, four, or five, &c. in the evening, according to the temperature of the day, giving moſt air in mild ſunny weather: waterings will be neceſſary during their abode here, about once a week, or ten or twelve days, as you ſhall ſee proper; and according to the weather and advanced period of the winter or ſpring, or power of the ſun, and at all times, while in the houſe, be ſure to water moderately, for much moiſture at this time would occaſion their leaves and young fruit, if any, to grow yellow, and very probably to drop. Their other further care in this department is, chiefly the waſhing their heads occaſionally from filth and inſects, clearing off decayed leaves, and protecting them from froſt, by ſecuring the windows, &c. the ſame as directed for the green-houſe plants in general. See GREEN-HOUSE PLANTS

In the open air their culture is—towards the latter end of May, or beginning of June, according to the temperature of the ſeaſon, begin to move theſe trees in their pots or tubs into the full air, placing them to adorn any particular part of the pleaſure ground, obſerving, when firſt brought forth, to waſh and clean their heads from duſt and other filth they may have contracted in the green-houſe. During the ſummer ſeaſon, ſupply them with water two or three times a week, or oftener, in very hot dry weather, at which time it is proper to lay ſome mowings of ſhort graſs on the ſurface of the pots or tubs, to preſerve the moiſture of the earth the better, obſerving now and then to water all over their heads; with this care they are to be continued in the open air till October, then remove them into the green-houſe, and manage them as before.

At any time of the year, when the ſurface of the earth in the pots or tubs binds, it is proper to ſtir it an inch or two deep; and if this is done in ſpring, and the looſe earth taken out, adding the ſame quantity of new, it will be very ſerviceable.

Shifting the plants into larger pots or tubs, and freſh earth, is neceſſary every ſecond or third ſpring at moſt, and April is the proper ſeaſon; draw them out of their preſent pots with the ball of earth entire; let all the outſide matted mouldy roots be pared off cloſe, and part of the old earth at top, ſides, and bottom, taken away: being then prepared with freſh compoſt, let the pot or tub be cleaned out, or, if a new larger one is neceſſary, have that ready, and lay ſome crooked pieces of tiles over the holes at bottom, and put in ſome earth; then place the tree in the pot or tub, and fill up the vacancy with more compoſt, preſſing it down on every ſide, finiſhing the work with a moderate watering, and retain the plants in the green-houſe till the end of May or beginning of June.

In thoſe years the plants do not require ſhifting, it is of much utility to looſen the earth in the top of the pots or tubs, as low as the ſurface of the roots, and down round the ſides; taking out the looſened earth, fill up the pot with freſh compoſt, and give water directly, to ſettle the earth cloſe.

Any of the trees having thin, ſtraggling, or irregular heads, the way to render them more regular, is to prune all the branches

moderately ſhort, nearly to an equal length, in March or April; at the ſame time ſhifting the plants, as above directed, and they will ſoon after break forth in the old wood into many young ſhoots, which you may regulate as you ſhall ſee neceſſary; or, if the ſhoots ariſe thinly, ſome of the ſtrongeſt may be topped in June, and they will furniſh laterals the ſame year to fill the head.

But ſuch of theſe trees as have very weak irregular heads, producing ſmall ill-coloured leaves, &c. it is adviſeable to prune the head pretty cloſe, and ſhift the tree into entire freſh earth; that is, ſhake all the old earth quite from the roots, then prune off all decayed roots and ſmall fibres, and tip the ends of the roots in general, and ſoak and waſh the whole in water, and then plant it in entire new compoſt, and directly give water; after this it would be of conſiderable advantage, where convenient, to plunge them in a bark hot-bed, made either in a glaſs-caſe, bark-pit, or even in the green houſe, in which let them remain until July, when they will have made ſtrong ſhoots, and form a new full and regular head, adorned with fine, large, luxuriant leaves.

When any of the ſorts of theſe trees have obtained a large ſize, they ſhould be ſhifted into tubs, hooped with iron hoops, and with two ſtrong hooked iron handles near the top of each tub, to receive poles to lift the trees in and out of the green-houſe. See TUBS, &c.

The flowering and fruit-ſetting ſeaſon of all the ſorts of *Citrus* is commonly in June and July; they are often very profuſe in flowers, particularly the Orange-tree, which, in healthful large trees, are generally greatly loaded with bloſſom: when they ſtand very thick, it is eligible to thin them a little, taking off the ſmalleſt; and, obſerving, as the trees continue blowing and ſetting their fruit for two months, that, when a full crop of fruit is ſet, it is of benefit to the trees and fruit, to gather off the ſuperabundant bloſſom as they are produced, though many permit them to remain for the ſake of their ornamental appearance.

The flowers which are thinned off, if they are not wanted for family uſe, for Orange-flower-water, &c. may, if any quantity of them, be ſold to good advantage, i. e. three or four ſhillings per pound weight; the chymiſts and perfumers often buy them; but in Covent-garden market in London there is always ready ſale for them, either in the open market, or in the phyſic-herb ſhops.

Compoſt, the moſt proper for all the ſorts of *Citrus*, is that of a light loamy nature, though they will all proſper in any rich garden earth. See COMPOSTS.

*Of planting them in the full Ground as Wall and Standard-Trees.*

In regard to planting theſe trees in the full ground, as already hinted, obſerve, that when this is intended, there muſt be frame-erections for the ſupport of glaſs and other covers, to defend the plants in inclement weather; and in which ſituation the trees, as having full ſcope for their roots, generally ſhoot ſtrong, and produce large fruit, and may either be trained as wall or ſtandard-trees.

A ſouth wall, in a dry ſituation, is a proper place for training them as wall-trees, againſt which may be erected wooden frame-work ſloping, either fixed or moveable, for the ſupport of glaſs frames for winter; likewiſe, for the greater protection of the trees in ſevere froſts, there may be a fire-place, with a flue or two, carried along a low wall in the front and ends; ſo plant the trees in the full border againſt the back wall, and train their branches thereto five or ſix inches diſtance, obſerving to defend them with the glaſſes from October till the middle or end of May, giving air and occaſional water as for thoſe in the green-houſe, and cover the glaſſes on nights in bad weather, and only in very ſevere froſt employ the flues, if any, with very moderate fires, &c. juſt to keep out the froſt; and in the beginning of June remove the glaſſes quite away, obſerving to lightly dig up the borders two or three times a year, and ſupply them with neceſſary manure annually.

To have the trees as ſtandards, a more capacious and lofty glaſs-caſe ſhould be erected againſt the wall, in the manner of a hot-houſe, but higher; ſo making a border the whole width and length, planting therein one or two rows of trees lengthways, ſuffering the trees to run up as ſtandards, giving only ſome neceſſary pruning, juſt to preſerve regularity; and as to their protection, &c. manage them as above directed.

In ſome places there are lofty moveable glaſs-caſes, ſo that two or three rows of trees are planted in a conſpicuous part of the pleaſure-ground, and in winter the frame is put over them, in ſummer taken wholly away; ſo they appear like a little Orange grove growing in the open ground; and if the trees are well protected by the glaſſes, and other occaſional

occaſional covers, &c. in winter, they will grow to a much greater height than thoſe in tubs.

CLASSIS, a Claſs, and in botany is the firſt and higheſt diviſion in the arrangement of plants ſyſtematically, and by which the whole vegetable kingdom is divided into twenty-four Claſſes, diſtinguiſhed by ſome eſſential and invariable mark in the fructification, poſſeſſed by all the plants of each reſpective Claſs; and by the ſame rule, each Claſs is ſubdivided into ſecondary diviſions or orders, the orders into genera, and each genera or genus into ſpecies, and the ſpecies into varieties. See ORDO, GENUS, SPECIES, and VARIETAS.

A Claſs, therefore, in botany, is defined to be an aſſemblage or collection of genera, that have ſome ſtriking mark in common, derived from the fructification, i. e. generative parts of the flower; as, for inſtance, one ſtamina, or male organ. Every genus and ſpecies, therefore, having flowers with one ſtamina, belong to the firſt Claſs, (*Monandria*, i. e. of *one* and *a man*); of two ſtamina, belongs to the ſecond Claſs, (*Diandria*, i. e. of *two* and *a man*); and of three ſtamina or male organs, to the third Claſs, (*Triandria*, i. e. of *three* and *a man*); and ſo of all the others, as explained under each head in the ſucceeding arrangement of the twenty-four Claſſes. Each of theſe Claſſes, as above noticed, are ſubdivided into ſections or orders, and that, as the eſtabliſhment of the Claſſes, is founded on the number of ſtamina, or male organs: the orders, or ſecondary diviſions, are founded principally upon the number and ſituation of the piſtil, i. e. ſtyle, or female organ, or ſome other ſtriking part of the fructification; as, for example, we obſerved above, that all plants having only one ſtamina, belong to the firſt Claſs, *Monandria*; of which Claſs there are but two orders, the firſt of which having one ſtyle, (*Monogynia*, i. e. of *one* and *a woman*) is *Monandria Monogynia*, one ſtamina and one ſtyle; the ſecond have two ſtyles, (*Digynia*, of *two* and *a woman*) is *Monanaria Digynia*, one ſtamina and two ſtyles: the ſame is alſo obſervable in the ſecond, third, and every ſucceeding Claſs, as is ſufficiently illuſtrated in the following arrangement of the twenty four Claſſes, and their reſpective ſecondary diviſions or orders, according to the Linnæan ſexual ſyſtem, as founded on the fructification or ſexes of plants. See SEXUS.

*Firſt Claſs.*

1. MONANDRIA, of *one* and *a man*, *one male organ*, comprehending plants with hermaphrodite flowers, having but one ſtamina, or male organ, and of which there are but two orders, theſe derived from the number of ſtyles in each order.

The orders are,

[1]MONANDRIA MONOGYNIA—one ſtamina and one ſtyle.

[2]MONANDRIA DIGYNIA—one ſtamina and two ſtyles.

*Second Claſs.*

2. DIANDRIA, of *twice*, or *two*, and *a man*, *two male organs*, plants with hermaphrodite flowers, having two ſtamina, or male organs, and conſiſts of three orders, derived from the number of ſtyles, or female organs, in each order.

The orders are,

[1]DIANDRIA MONOGYNIA—two ſtamina and one ſtyle.

[2]DIANDRIA DIGYNIA—two ſtamina and two ſtyles.

[3]DIANDRIA TRIGYNIA—diandrous plants with three ſtyles.

*Third Claſs.*

3. TRIANDRIA, of *three* and *a man*, *three male organs*, plants having hermaphrodite flowers, with three ſtamina, or male organs, and conſiſts of but three orders.

The orders are.

[1]TRIANDRIA MONOGYNIA—three ſtamina and one ſtyle.

[2]TRIANDRIA DIGYNIA—three ſtamina and two ſtyles.

[3]TRIANDRIA TRIGYNIA—three ſtamina and three ſtyles.

*Fourth Claſs.*

4. TETRANDRIA, of *four*, &c. comprehends plants having hermaphrodite flowers, with four ſtamina of equal length, and compriſes three orders.

The orders are,

[1]TETRANDRIA MONOGYNIA—four ſtamina and one ſtyle.

[2]TETRANDRIA DIGYNIA—four ſtamina and two ſtyles.

[3]TETRANDRIA TETRAGYNIA—four ſtamina and four ſtyles.

*Fifth Claſs.*

5. PENTANDRIA, of *five* and *a man*, *five male organs*, compriſes plants having hermaphrodite flowers, with five ſtamina, and conſiſts of ſix orders.

The orders are,

[1]PENTANDRIA MONOGYNIA—five ſtamina and one ſtyle.

[2]PENTANDRIA DIGYNIA—five ſtamina and two ſtyles.

[3]PENTANDRIA TRIGYNIA—five ſtamina and three ſtyles.

[4]PENTANDRIA TETRAGYNIA—five ſtamina and four ſtyles.

[5]PENTANDRIA PENTAGYNIA—five ſtamina and five ſtyles.

[6]PENTANDRIA POLYANDRIA—five ſtamina and many ſtyles.

*Sixth Claſs.*

6. HEXANDRIA, of *ſix* and *a man*, *ſix male organs*, plants with hermaphrodite flowers, having ſix ſtamina, and comprehends five orders.

The orders are,

[1]HEXANDRIA MONOGYNIA—ſix ſtamina and one ſtyle.

[2]HEXANDRIA DIGYNIA—ſix ſtamina and two ſtyles.

[3]HEXANDRIA TRIGYNIA——ſix ſtamina and three ſtyles.

[4]HEXANDRIA TETRAGYNIA—ſix ſtamina and four ſtyles.

[5]HEXANDRIA POLYGYNIA—ſix ſtamina and many ſtyles.

*Seventh Claſs.*

7. HEPTANDRIA, of *ſeven*, *&c.* conſiſting of plants with hermaphrodite flowers, having ſeven ſtamina, and furniſhes four orders.

The orders are,

[1]HEPTANDRIA MONOGYNIA—ſeven ſtamina and one ſtyle.

[2]HEPTANDRIA DIGYNIA—ſeven ſtamina and two ſtyles.

[3]HEPTANDRIA TETRAGYNIA—ſeven ſtamina and four ſtyles.

[4]HEPTANDRIA HEPTAGYNIA—ſeven ſtamina and ſeven ſtyles.

*Eighth Claſs.*

8. OCTANDRIA, of *eight* and *a man*, *eight male organs*, plants with hermaphrodite flowers, having eight ſtamina, or male organs, and comprehends four orders.

The orders are,

[1]OCTANDRIA MONOGYNIA—eight ſtamina and one ſtyle.

[2]OCTANDRIA DIGYNIA—eight ſtamina and two ſtyles.

[3]OCTANDRIA TRIGYNIA—eight ſtamina and three ſtyles.

[4]OCTANDRIA TETRAGYNIA—eight ſtamina and four ſtyles.

*Ninth Claſs.*

9. ENNEANDRIA, of *nine*, *&c.* comprehends plants with hermaphrodite flowers, having nine ſtamina, and conſiſts of three orders.

The orders are,

[1]ENNEANDRIA MONOGYNIA—nine ſtamina and one ſtyle.

[2]ENNEANDRIA TRIGYNIA—nine ſtamina and three ſtyles.

[3]ENNEANDRIA HEXAGYNIA—nine ſtamina and ſix ſtyles.

*Tenth Claſs.*

10. DECANDRIA, of *ten* and *a man*, *ten male organs*, plants with hermaphrodite flowers, having ten ſtamina, or male organs, and it conſiſts of five orders.

The orders are,

[1]DECANDRIA MONOGYNIA—ten ſtamina and one ſtyle.

[2]DECANDRIA DIGYNIA—ten ſtamina and two ſtyles.

[3]DECANDRIA TRIGYNIA—ten ſtamina and three ſtyles.

[4]DECANDRIA PENTAGYNIA—ten ſtamina and five ſtyles.

[5]DECANDRIA DECAGYNIA—ten ſtamina and ten ſtyles.

*Eleventh Claſs.*

11. DODECANDRIA, of *twelve* and *a man*, *twelve male organs*, compriſes plants with hermaphrodite flowers, having twelve or more ſtamina, or male organs, and conſiſts of ſix orders.

The orders are,

[1]DODECANDRIA MONOGYNIA—twelve or more ſtamina and one ſtyle.

[2]DODECANDRIA DIGYNIA——twelve or more ſtamina and two ſtyles.

[3]DODECANDRIA TRIGYNIA—twelve or more ſtamina and three ſtyles.

[4]DODECANDRIA PENTAGYNIA—twelve or more ſtamina and five ſtyles.

[5]DODECANDRIA OCTAGYNIA—twelve or more ſtamina and eight ſtyles.

[6]DODECANDRIA DODECAGYNIA—twelve or more ſtamina and twelve ſtyles.

*Twelfth Claſs.*

12. ICOSANDRIA, of *twenty* and *a man*, or *huſband*, *twenty male organs*, conſiſts of plants with hermaphrodite flowers, having about twenty or more ſtamina, or male organs,

gans, that are inſerted either into the inner ſide of the calix, or to the corolla; by this laſt circumſtance is the Claſs in queſtion diſtinguiſhed from that immediately following, *Polyandria*, which have alſo frequently about twenty ſtamina, but they are inſerted into the receptacle. This Claſs, *Icoſandria*, is alſo diſtinguiſhable by having a monophyllous, hollow, or concave calix, and to the inner ſide of which the petals are faſtened by their claws; and there are five orders.

The orders are,

[1]ICOSANDRIA MONOGYNIA—twenty or more ſtamina and one ſtyle.

[2]ICOSANDRIA DIGYNIA—twenty or more ſtamina and two ſtyles.

[3]ICOSANDRIA TRIGYNIA—twenty or more ſtamina and three ſtyles.

[4]ICOSANDRIA PENTAGYNIA—twenty or more ſtamina and five ſtyles.

[5]ICOSANDRIA POLYGYNIA——twenty or more ſtamina and many ſtyles.

*Thirteenth Claſs.*

13. POLYANDRIA, of *many* and *a man*, or *huſband*, *many male organs*, plants with hermaphrodite flowers, having many ſtamina, or male organs, which in this Claſs are inſerted into the receptacle, and which diſtinguiſhes it from that immediately preceding, *Icoſandria*, where the ſtamina are alſo numerous, but are attached to the inner part of the calix, &c. therefore all plants having more than twelve ſtamina inſerted in the *receptaculum* are of this Claſs, *Polyandria*, and conſiſts of ſeven orders.

The orders are,

[1]POLYANDRIA MONOGYNIA—many ſtamina and one ſtyle.

[2]POLYANDRIA DIGYNIA—many ſtamina and two ſtyles.

[3]POLYANDRIA TRIGYNIA—many ſtamina and three ſtyles.

[4]POLYANDRIA TETRAGYNIA—many ſtamina and four ſtyles.

[5]POLYANDRIA PENTAGYNIA—many ſtamina and five ſtyles.

[6]POLYANDRIA HEXAGYNIA—many ſtamina and ſix ſtyles.

[7]POLYANDRIA POLYGYNIA—many ſtamina and numerous ſtyles.

*Fourteenth Claſs.*

14. DIDYNAMIA, of *twice*, and *power*, *two powers*, comprehends plants with hermaphrodite flowers, having two long and two ſhort ſtamina: in this circumſtance of the ſtamina, long and ſhort, conſiſts the main difference between the Claſs in queſtion, and that of the fourth, which have alſo four ſtamina, but which are of equal length; therefore all plants having four ſtamina that are of unequal length, two of them long, and two ſhort, are didynamous, i. e. of the Claſs *Didynamia*, of which there are but two families or orders, and are founded upon the abſence and preſence of the *pericarpium*, or ſeed-veſſel

The orders are,

[1]DIDYNAMIA GYMNOSPERMIA—— two long and two ſhort ſtamina, and naked ſeeds (*gymnoſpermia*) lodged in the calix.

[2]DIDYNAMIA ANGIOSPERMIA—two long and two ſhort ſtamina, and covered ſeeds (*angioſpermia*) lodged in a proper pericarpium, or ſeed-veſſel.

*Fifteenth Claſs.*

15. TETRADYNAMIA, of *four*, and *power*, *four powers*, plants with hermaphrodite flowers, having four long and two ſhort ſtamina, and conſiſts of two orders, founded on the pericarpium; ſuch as have a ſhort round pod, (*ſiliculoſa*) as honeſty and Candy tuft, and ſuch as have a long pod (*ſiliquoſa*), as ſtock-gilliflower, &c.

The orders are,

[1]TETRADYNAMIA SILICULOSA—— four long and two ſhort ſtamina, and ſhort round pods.

[2]TETRADYNAMIA SILIQUOSA—four long and two ſhort ſtamina, and long ſeed-pods.

*Sixteenth Claſs.*

16. MONADELPHIA, of *alone* and *a brotherhood*, *one brotherhood*, hermaphrodite flowers, having all the ſtamina united below into one body, forming a column, through which paſſes the ſtyle; and the orders are five, founded on the number of united ſtamina.

The orders are,

[1]MONADELPHIA PENTANDRIA--five monadelphous ſtamina.

[2]MONADELPHIA DECANDRIA—ten monadelphous ſtamina.

[3]MONADELPHIA ENDECANDRIA—eleven monadelphous ſtamina.

[4]MONADELPHIA DODECANDRIA—twelve or more monadelphous ſtamina.

[5]MONADELPHIA POLYANDRIA—numerous monadelphous ſtamina.

*Seventeenth Claſs.*

17. DIADELPHIA, of *twice* and *a brotherhood*, *two brotherhoods in the ſame flower*, hermaphrodite flowers, having two ſets or columns

columns of united ſtamina, i. e. united below into two different bodies; the flowers are all papilionaceous, and have apparently ten ſtamina, but which are only two, one of which ſplits longitudinally from the middle upward, and terminates in about nine parts, appearing like ſo many diſtinct filaments; and the other ſtamina is ſimple or undivided, and lies cloſely along the fiſſure of the divided filament, which have generally as many antheræ as diviſions, and the ſimple ſtamina have but one antheræ; and from the number of antheræ in both filaments is founded the orders, which are four.

The orders are,

[1]DIADELPHIA PENTANDRIA—diadelphous ſtamina, having five antheræ.

[2]DIADELPHIA HEXANDRIA—diadelphous ſtamina with ſix antheræ.

[3]DIADELPHIA OCTANDRIA—diadelphous ſtamina with eight antheræ.

[4]DIADELPHIA DECANDRIA—diadelphous ſtamina with ten antheræ.

*Eighteenth Claſs.*

18. POLYADELPHIA, of *many brotherhoods*, *many brotherhoods*, *or unions of ſtamina*, *in the ſame flower*, hermaphrodite flowers that have each many ſets of united ſtamina, i. e. united by their filaments into ſeveral diſtinct bodies, and conſiſts of three orders, derived from the number of ſtamina or antheræ, appearing in each flower.

The orders are,

[1]POLYADELPHIA PENTANDRIA—five polyadelphous ſtamina in each ſet.

[2]POLYADELPHIA ICOSANDRIA—twenty polyadelphous ſtamina.

[3]POLYADELPHIA POLYANDRIA—many polyadelphous ſtamina.

*Nineteenth Claſs.*

19. SYNGENESIA, of *together* and *generation*, plants with compound flowers, having all the antheræ, or generative male organs, united into one cylindric body, and through which the ſtyle, or generative female organ, riſes, uniting in the ſame manner.

This Claſs contains the numerous tribe of compound flowers, ſee COMPOSITUS *Flos*; and the orders, or ſecondary diviſions, ariſe from the different modes of intercommunication, or polygamia of the florets that compoſe each flower; ſuch as, the florets all hermaphrodites—hermaphrodites and females—hermaphrodites of no ſex or neuter—males and females—the florets in diſtinct cups within the main one—ſimple florets; ſo that this Claſs is divided into ſix orders.

The orders are,

[1]SYNGENESIA POLYGAMIA ÆQUALIS—equal polygamia, or the florets all hermaphrodites.

[2]SYNGENESIA POLYGAMIA SUPERFLUA—ſuperfluous polygamia, or the florets of the diſk all hermaphrodites, and the circumference or radius all females, which latter are ſaid to be ſuperfluous or uſeleſs, becauſe the impregnation of them is unneceſſary, the fructification being completed in the hermaphrodites in the centre.

[3]SYNGENESIA POLYGAMIA FRUSTANEA—fruſtrated polygamia, i. e. the florets in the radius are neuter, or of no ſex, being devoid both of ſtamina and ſtyle, ſo are ineffectual to the fructification, as in the caſe of ſunflower, &c. in which the fructification is perfected only, in the hermaphrodites, in the diſk.

[4]SYNGENESIA POLYGAMIA NECESSARIA—neceſſary polygamia, or being male and female florets, and no hermaphrodites, the preſence of the male and females is neceſſary for perfecting the fructification.

[5]SYNGENESIA POLYGAMIA SEGREGATA—ſeparated polygamia, the florets of each flower ſeparated from each other by means of partial cups, containing one or more florets, and ſtand within the general calix, as in globe-thiſtle and elephant's foot.

[6]SYNGENESIA POLYGAMIA MONOGAMIA—monogamous or ſimple florets, the flower having only one floret in each general calix, as in balſamine, *impatiens*.

*Twentieth Claſs.*

20. GYNANDRIA, of *a woman* and *a man*, plants having the ſtamina or male organs placed either upon the ſtyle or female organ, or the common receptacle elongated in the form of a ſtyle, ſupporting both the piſtillum and ſtamina; and is divided into ſeven orders, founded each on the number of ſtamina in each flower.

The orders are,

[1]GYNANDRIA DIANDRIA—two gynandrous ſtamina in each flower.

[2]GYNANDRIA TRIANDRIA—three gynandrous ſtamina in each flower.

[3]GYNANDRIA TETRANDRIA—four gynandrous ſtamina in each flower.

[4]GYNANDRIA PENTANDRIA—five gynandrous ſtamina in each flower.

[5]GYNANDRIA HEXANDRIA—ſix gynandrous ſtamina in each flower.

[6]GYNANDRIA DECANDRIA—ten gynandrous ſtamina in each flower.

[7]GYNANDRIA

[7]GYNANDRIA POLYANDRIA—many gynandrous ſtamina in each flower.

*Twenty firſt Claſs.*

21. MONOECIA, of *alone* and *a houſe*, plants with male and female flowers apart, or alone, in ſeparate cups; that is, within different cups on the ſame plant, as in the cucumber, &c. and is divided into eleven orders, ariſing from the number, union, and ſituation of the ſtamina of the male flowers.

All monoecious plants are alſo termed androgynous, from the ſame circumſtances of male and female flowers on different parts of the ſame plant. See ANDROGYNIA.

The orders are,

[1]MONOECIA MONANDRIA— monoecious plants with one ſtamina.

[2]MONOECIA DIANDRIA——monoecious plants with two ſtamina.

[3]MONOECIA TRIANDRIA — monoecious plants with three ſtamina.

[4]MONOECIA TETRANDRIA—monoecious plants with four ſtamina.

[5]MONOECIA PENTANDRIA—monoecious plants with five ſtamina.

[6]MONOECIA HEXANDRIA — monoecious plants with ſix ſtamina.

[7]MONOECIA HEPTANDRIA—monoecious plants with ſeven ſtamina.

[8]MONOECIA POLYANDRIA— monoecious plants with numerous ſtamina.

[9]MONOECIA MONADELPHIA—monoecious plants with monadelphous or united ſtamina, i. e. all the ſtamina united below into one cylindric body.

[10]MONOECIA SYNGENESIA—monoecious plants with ſyngeneſious antheræ; that is, with all the antheræ, or tops of the ſtamina, united into a cylinder, as in the cucumber, gourd, bryony, &c. See Claſs SYNGENESIA.

[11]MONOECIA GYNANDRIA—monoecious plants with gynandrous ſtamina, i. e. the filaments ſituated upon a ſort of imperfect ſtyle. See the Claſs GYNANDRIA.

*Twenty-ſecond Claſs.*

22. DIOECIA, of *twice* and *an habitation, two habitations*, male and female flowers on two ſeparate plants; that is, all the plants of this Claſs are either male or female, not hermaphrodite, as in the greater number of Claſſes; nor with male and female on the ſame plant, as in the immediately preceding Claſs, *Monoecia*, but male and female flowers on diſtinct plants, as in the genus *cliffortia*, *coriaria*, *carica*, moonſeed, ſpinach, hop, and many others; and the female plants only produce ſeeds, which, however, require the vicinity of a male plant, or the aſperſion of the male duſt to impregnate the female flowers, or at leaſt to render the ſeeds fertile; and from the ſeeds of the females, both male and female plants are produced.

This Claſs is divided into fourteen orders, and are founded upon the number, union, and ſituation of the ſtamina of the male plants.

The orders are,

[1]DIOECIA MONANDRIA—dioecious male plants with one ſtamina.

[2]DIOECIA DIANDRIA——dioecious male plants with two ſtamina.

[3]DIOECIA TRIANDRIA—dioecious male plants with three ſtamina.

[4]DIOECIA TETRANDRIA—dioecious male plants with four ſtamina.

[5]DIOECIA PENTANDRIA—dioecious male plants with five ſtamina.

[6]DIOECIA HEXANDRIA—dioecious male plants with ſix ſtamina.

[7]DIOECIA OCTANDRIA—dioecious male plants with eight ſtamina.

[8]DIOECIA ENNEANDRIA—dioecious male plants with nine ſtamina.

[9]DIOECIA DECANDRIA—dioecious male plants with ten ſtamina.

[10]DIOECIA DODECANDRIA——dioecious plants with twelve ſtamina.

[11]DIOECIA POLYANDRIA——dioecious male plants with numerous ſtamina.

[12]DIOECIA MONADELPHIA——dioecious male plants with monadelphous or united ſtamina, being united by their filaments into a pillar or column, as in ſhrubby horſe-tail.

[13]DIOECIA SYNGENESIA—dioecious male plants with ſyngeneſious antheræ, i. e. with the antheræ or tops of the filaments united.

[14]DIOECIA GYNANDRIA—dioecious male plants with gynandrous ſtamina, or that are ſituated on a kind of ſtyle. See the Claſs GYNANDRIA.

*Twenty third Claſs.*

23. POLYGAMIA, of *many* and *marriage*, plants of a variety of ſexes, that is, hermaphrodite flowers, and likewiſe male or female flowers, or both on the ſame plant, or on diſtinct plants of the ſame genus; and from the different circumſtances of polygamia this Claſs is divided into three orders.

The orders are,

[1]POLYGAMIA MONOECIA—the polygamia all on the ſame plant.

[2]POLYGAMIA DIOECIA— the polygamia on two diſtinct plants.

[3]POLY-

[3]POLYGAMIA TRIOECIA—the polygamia on three diſtinct plants.

*Twenty-fourth Claſs.*

24. CRYPTOGAMIA, of *to hide* or *conceal* and *a marriage*, *a clandeſtine marriage*,—plants that have their fructifications either entirely concealed, or, from their minuteneſs or ſituation, are imperfectly viſible: ſuch are the ferns, moſſes, flags, ſea-weed or wrack, and muſhrooms, and of which the claſſic character is very imperfect, and the genera of courſe without any eſſential mark or diſtinction, ſo great is the obſcurity that ſtill prevails in this conſiderable part of the vegetable kingdom.

This Claſs of imperfect plants is divided into four orders or families, very different in their general habit.

The orders are,

[1]CRYPTOGAMIA FILICES—the *Filices* or Ferns.

This is a large tribe of plants, defined to be plants which bear their flower and fruit on the back of their leaves; but the flower and other parts of fructification are ſo minute, or imperfectly viſible, that they do not admit of any regular claſſic diſtinction. See FILICES.

[2]CRYPTOGAMIA MUSCI—*Muſci* or Moſſes.

This is alſo a large tribe of plants with imperfectly diſtinguiſhable fructifications: their chief characteriſtic diſtinction is—antheræ without filaments—male flowers, conſtituted by the preſence of the antheræ—the antheræ have, or are deſtitute of a *calyptra*—ſeeds intirely naked, being devoid of the cotyledon or cover, ſo exhibit the naked embrio. See MUSCI.

[3]CRYPTOGAMIA ALGÆ—*Algæ*, Flags or Sea-weed.

A numerous tribe of imperfect plants, whoſe root, ſtem, and leaf are all one, and their fructification imperfectly known.

[4]CRYPTOGAMIA FUNGI—*Fungi*, or Muſhrooms.

A very extenſive tribe of plants, whoſe fructification is ſtill entirely unknown. See FUNGI.

By the foregoing arrangement of the twenty-four Claſſes of the vegetable kingdom, and their reſpective orders, the ſtudent in gardening and botany will eaſily explain to himſelf the proper Claſs and order of all the different genera; eſpecially, as to each genus we have all along ſubjoined the name of the Claſs and order to which it belongs; obſerving, that all the different ſpecies and varieties of each genera or genus, are alſo all of the ſame Claſs and order.

CLEMATIS, Climber, or Virgin's-Bower, and Traveller's-Joy, &c.

This genus furniſhes ſeveral ſhrubby climbers of the flowery tribe, and two herbaceous, upright, flowery perennials, all of hardy growth; adorned ſome with winged, others with divided, and ſome with ſimple leaves; and all of them with quadripetalous flowers.

Claſs and order, *Polyandria Polygynia.*

*Characters.*] CALIX none. COROLLA, four oblong looſe petals. STAMINA, numerous awl-ſhaped filaments, with the antheræ growing to their ſides. PISTILLUM, numerous, roundiſh, compreſſed germina, ſubulated ſtyles, and ſimple ſtigmas. PERICARPIUM none. SEMINA, numerous roundiſh ſeeds, collected into a head, with the ſtyles adhering thereto.

The ſpecies are as follow.

The firſt ſeven ſpecies are ſhrubby climbers, having ſlender ſtalks and branches, climbing or mounting themſelves on ſupport by *cirrhus* or claſpers, many feet high.

[1]CLEMATIS *Viticella.*

*Viticella, or Virgin's-Bower Clematis.*] Clematis with ſhrubby climbing ſtalks, branching at every joint, and mounting upon ſupport fifteen or twenty feet high; compound and decompound leaves of many oval entire lobes, and numerous ſlender foot-ſtalks by threes, each ſupporting one flower, of different colours in different varieties.

*Varieties are*] Virgin's-Bower with ſingle blue flowers—ſingle red flowers—ſingle purple flowers—double purple flowers; all of them appearing in July and Auguſt.

This ſpecies and varieties obtain the name Virgin's-Bower, from their peculiar excellence in forming arbours or bowers, &c. they being admirable climbers, and often ſhoot ten or fifteen feet in one year, ſpreading their branches numerouſly every way, and very cloſely covered from bottom to top with leaves and flowers; but the double-flowered variety is the moſt beautiful, its petals being ſo numerous as to obliterate the fructification, and continues the longeſt in bloom. They are all well calculated for training over covered arbours, or rural ſeats, or againſt naked walls or other fences.

[2]CLEMATIS *Vitalba.*

*Vitis-alba, Great White Climber, Traveller's-Joy, and Old Man's Beard.*] Clematis with ſhrubby, tough, climbing ſtalks, very branchy and

and cirrhous, mounting upon ſupport twenty feet high, garniſhed with winged climbing leaves of five or ſeven heart-ſhaped lobes, and numerous bunches of white flowers, ſucceeded by compact cluſters of ſeeds, terminated by long white hairy plumes, hanging down like beards; hence ſometimes called Old Man's Beard.

It grows wild in England in hedges, mounting by its numerous claſpers over the buſhes and trees in its neighbourhood, ſpreading widely every way, that the hedges are often covered with its flowers in ſummer, and its white-bearded ſeeds in autumn and winter, appearing ſingular and ornamental, whereby, as growing abundantly by road ſides, affording entertainment to paſſengers, is alſo called Traveller's-Joy; it is rarely admitted in gardens, though a few plants, properly diſpoſed in large ſhrubbery-works, will have an agreeable effect as climbers.

[3]CLEMATIS *Viorna.*

*Viorna, or Virginian Purple Climber.*] Clematis with ſhrubby climbing ſtalks, branching and riſing on ſupport eight or ten feet high; compound and decompound leaves of nine nearly heart-ſhaped, ſometimes trifid lobes; and purpliſh-blue flowers, having thick coriaceous petals, appearing in July and Auguſt.

[4]CLEMATIS *Orientalis.*

*Oriental Yellow Climber.*] Clematis with ſhrubby climbing ſtalks and branches, mounting upon ſupport ſix or eight feet high; compound leaves of nine folioles, cut angularly into wedge-ſhaped lobes; and yellowiſh green flowers in April and May.

[5]CLEMATIS *Virginiana.*

*Virginian Ternate-leaved White Climber.*] Clematis with ſhrubby climbing ſtalks and branches, riſing on ſupport many feet high; ternate or trifolate leaves, of three heart-ſhaped, angular, lobated lobes, and white flowers.

[6]CLEMATIS *Criſpa.*

*Carolina Curled-flowered Climber.*] Clematis with ſhrubby climbing ſtalks, branchy, and riſing upon ſupport four or five feet high; ſimple and trifoliate leaves, the folioles in ſome entire, others divided into three lobes; and purple flowers, having thick curled petals, appearing in July and Auguſt.

[7]CLEMATIS *Cirrhoſa.*

*Cirrhoſe Evergreen Climber.*] Clematis with ſhrubby climbing ſtalks, very branchy, buſhy, and cirrhous, mounting upon ſupport ſix or eightfeet high; ſimple evergreen leaves, ſometimes biſid, and ſome cut into three lobes; and greeniſh flowers, appearing in winter.

The two following are herbaceous, and of upright growth.

[8]CLEMATIS *Recta.*

*Upright White Clematis.*] Clematis with fibrey perennial roots; upright annual ſtalks a yard high; winged oppoſite leaves of three or four pair of oval-ſpear-ſhaped entire lobes, terminated by an odd one; and at top of the ſtalks, white flowers in large panicles, appearing in June.

*Variety.*] Low upright white Clematis with large flowers.

[9]CLEMATIS *Integrifolia.*

*Upright Entire-leaved Blue Clematis.*] Clematis with fibrey perennial roots; upright annual ſtalks a yard high; large, ſimple, ſpear-ſhaped, entire leaves, growing oppoſite; and from the upper part of the ſtalks, many long naked foot-ſtalks, each ſupporting a large blue flower, appearing in June.

The flowers of all the ſpecies, in their natural ſingle ſtate, are compoſed each of four oblong petals, and in all the climbing kinds are remarkably numerous, ariſing from almoſt every part of the branches at the axillas of the leaves, ſucceeded, in ſeveral of the climbers, and both the upright herbaceous ſorts, with abundance of ſeed in autumn, growing in cluſtered heads, all of which, being furniſhed with long white plumes, have a ſingular appearance in autumn and winter.

All the ſpecies, both climbers and upright kinds, are very hardy, and proſper in any common ſoil of a garden, and in any expoſure.

The firſt ſeven ſorts are of climbing growth, and having durable ſtalks, but which being long, ſlender, and weak, muſt have ſupport either of trellis-work, ſtrong ſtakes, walls, paling, or hedges, &c. otherwiſe their branches will trail on the ground; ſo that they are proper to train over covered arbours, or againſt high naked walls, or the like; or may be introduced in large ſhrubbery or wood-works, here and there one, to run over the buſhes; and ſome may alſo be planted ſingly in large clumps between deciduous ſhrubs, placing tall ſtrong ſtakes for their ſupport.

Of theſe climbing kinds, the firſt ſort, Virgin's-Bower and varieties, have the greateſt merit for ornament, and are the ſorts that are principally known and cultivated in the Britiſh gardens.

The eighth and ninth ſorts are proper furniture

niture for any of the compartments of the pleaſure-ground, and they will ſucceed any where; they are particularly well calculated to occupy vacant ſpaces in the ſhrubbery clumps, where they will ſhew themſelves to great advantage.

*Propagation of all the Sorts.*

All the ſhrubby climbing kinds are propagated by layers, and ſome of them alſo by cuttings.

By layers: the young ſhoots of the ſame year are the proper parts for propagation, and if theſe are layed in ſummer, before they become woody, they will more certainly ſucceed; therefore, when the ſhoots of the year are two or three feet long, let the branches on which they grow be brought down and pegged in the ground; then lay all the young ſhoots in the earth, in the uſual way, with their tops three or four inches out, and by October moſt of them will be rooted, when, or in ſpring following, they may be tranſplanted into the nurſery.

This method of ſummer laying is more particularly neceſſary for the Virgin's-Bower and varieties, and moſt of the foreign climbers.

The Traveller's-Joy and Evergreen Climber, however, may be layed at any time; they will alſo grow by cuttings of the young ſhoots in ſpring or ſummer, though thoſe of the latter rather require aid of a hot bed; and the Evergreen ſort often ſend up ſuckers from the bottom, each of which, tranſplanted, becomes a good plant.

The two upright herbaceous ſorts are eaſily propagated, by dividing their roots in autumn, or early in ſpring. which multiply exceedingly, and may be divided every two or three years; every ſlip having a fibre at bottom, and bud at top, will readily grow.

Theſe two ſorts may alſo be raiſed from ſeeds, in a bed or border of common earth, ſown in autumn, or early in ſpring; and when the plants are a year old, they will produce flowers.

CLETHRA, *Clethra.*

There is but one ſpecies, a deciduous flowering ſhrub for the ſhrubbery.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, monophyllous, five-parted, and permanent. COROLLA, five oblong petals, broadeſt towards the extremeties. STAMINA, ten filaments, and oblong erect antheræ. PISTILLUM, roundiſh germen, permanent ſtyle, and trifid ſtigma. PERICARPIUM, a roundiſh, trivalvular, trilocular capſule, lodged in the calix, and many angular ſeeds.

The ſpecies is,

CLETHRA *Alnifolia.*

*Alder-leafed American Clethra.*] Clethra with a ſhrubby ſtem, dividing into a branchy head four or five feet high; long, ſpear-ſhaped, ſerrated, alternate leaves; and at the ends of the branches long ſpikes of white flowers in July or Auguſt.

This is a very ornamental ſhrub, but more particularly during its bloom, and merits a place in every curious collection, allowing it rather a moiſt than dry ſoil.

It is propagated by ſeeds, layers, and ſuckers.

By ſeeds: theſe are procured from America, and ſown in pots of light earth, to move to ſhade in ſummer, and ſhelter in winter, becauſe the plants ſometimes do not come up till the ſecond ſpring. By layers: perform it on the young ſhoots in autumn; water them the following ſummer, and by autumn after they will be rooted, though it is ſometimes two years before that is accompliſhed. Suckers from the root may be tranſplanted in autumn or ſpring, being careful to take them up with fibres.

CLIFFORTIA, *Cliffortia.*

It furniſhes three evergreen African ſhrubs for the green-houſe, adorned with ſimple and trifoliate leaves, and apetalous flowers.

Claſs and order, *Dioecia Polyandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, having cups compoſed of three oval acute leaves; thoſe of the females are permanent. COROLLA, no petals. STAMINA, numerous erect filaments in the males, and oblong, twin, compreſſed antheræ. PISTILLUM, in the females, an oblong germen under the calix, two plumoſe ſtyles, and ſimple ſtigmas. PERICARPIUM, an oblong, taper, bilocular capſule, crowned by the calix, and contains one ſeed.

The ſpecies are,

[1]CLIFFORTIA *Ilicifolia.*

*Ilex-leafed Cliffortia.*] Cliffortia with a ſhrubby ſlender ſtem, very branchy, and forming a diffuſed head four or five feet high; ſtiff leaves, heart-ſhaped at the baſe, broad and indented at the ends; and yellowiſh-green cloſe-ſitting flowers, growing ſingly.

[2]CLIFFORTIA *Ruſcifolia.*

*Ruſcus-leafed Cliffortia.*] Cliffortia with a ſhrubby

ſhrubby ſlender ſtalk, forming a branchy head three or four feet high; ſmall, ſpear-ſhaped, ſtiff, entire leaves, in cluſters; and between them looſe bunches of yelloviſh green flowers.

[3]CLIFFORTIA *Trifoliata.*

*Three-leafed Cliffortia.*] Cliffortia with a ſhrubby very ſlender ſtem, branching and forming a ſpreading head three or four feet high; trifoliate cloſe-ſitting leaves, having the middle lobe tridented, and yelloviſh-green flowers almoſt cloſe to the branches.

The flowers of all the ſpecies are apetalous, ſo make no great appearance, but are the moſt conſpicuous in the male plants, by their numerous, yellow, erect ſtamina.

All the three ſpecies, conſidered as evergreens, are very ornamental, and being natives of Æthiopia, require ſhelter here in winter; ſo muſt be kept in pots of rich light earth, and placed in the greenhouſe collection, giving plenty of water in ſummer, and but very ſparingly in winter.

Their propagation is generally effected by cuttings in this country, which muſt be young ſhoots of five or ſix inches length, planting them in pots in ſpring or ſummer, and plunge them in a hot-bed, they will readily take root.

They may alſo be propagated by layers in the ſpring.

CLIMBING PLANTS, plants whoſe ſtalks either aſcend ſpirally round any adjacent ſupport, or climb by means of claſpers or tendrils. See CIRRHUS.

Of Climbers, there are both herbaceous and woody plants, and which may be divided into three kinds, according to their mode of climbing; ſuch as Twining Climbers, Cirrhoſe Climbers, Paraſitic Climbers.

Twining Climbers; ſuch as have winding ſtalks *(caulis volubilis)* and which twiſt or aſcend themſelves ſpirally about any neighbouring ſupport, as ſcarlet kidney beans, hops, convolvulus major, and ſome ſpecies of honeyſuckle.

Cirrhoſe Climbers; ſuch that aſcend thro' means of claſpers, tendrils, or ſpiral ſtrings, iſſuing from the ſides of the ſtalks and branches *(cauli cirrhoſus)*, or from the foot-ſtalks of the leaves, and even from the leaves themſelves, ſo twiſt about any thing they encounter, whereby their ſtalks are ſupported and arrive at the height nature deſigned them: examples of this ſort are, almoſt all the pea tribe, cucumber, vine, paſſion-flower, traveller's-joy, *ſmilax*, or rough bindweed, and many other ſorts.

Paraſitic Climbers; theſe are alſo of the cirrhoſe tribe, but their cirrhi, or claſpers, plant themſelves like roots in the bark of the adjoining trees *(cauli paraſiticus)*, ſo the plant thereby ſupports itſelf like a paraſite, on other plants, and mount to their tops; ſuch as the ivy, radicant bignonia, woody night-ſhade, and ſeveral others: theſe ſort of Climbers alſo root in walls, pales, or any kind of buildings, and aſcend to their tops, if ever ſo high.

Many of the climbing and trailing tribe are very ornamental in gardens, both of the herbaceous and ſhrubby kinds; the following is a liſt of the principal ſorts.

Of the herbaceous kinds are, *convolvulus*, ſeveral ſpecies and varieties—everlaſting-pea—painted-lady-pea—*cynanchum*, ſeveral ſpecies—ſcarlet kidney-bean, and white varieties——naſturtium——gourd—hop-plant—*tamus*, or black briony—Cretan black briony—*brionia*, or white-briony—*ipomoea coccima*, or ſcarlet convolvulus, and ſome others.

All theſe herbaceous Climbers may be allowed places in large borders, placing ſticks for their ſupport, upon which moſt of them will naturally climb, and appear very ornamental in ſummer.

Some of the more aſpiring ſorts may alſo be placed to run over arbours, or any kind of rural ſeats in gardens.

Of ſhrubby kinds, or ſuch as have perennial ſtalks, are the following: radicant and evergreen *bignonia*—climbing *celaſtrus*—*clematis*, virgin's-bower, ſeveral ſpecies and varieties—*glycine*, or kidney-bean-tree of Carolina—ivy—honeyſuckle, many ſorts—*moniſpermum*, or moon-ſeed, two or three ſpecies—*paſſiflora*, or paſſion-flower—*periploca*, or Virginia-ſilk—*rubus*, or bramble, ſeveral ſorts—*ſmilax*, or rough bindweed—woody night-ſhade, two or three varieties—*vinca*, or periwinkle, many varieties—*vitis*, the vine.

All theſe ſhrubby Climbers, conſidered as plants of ornament, are proper furniture for ſhrubberies of any conſiderable extent, and may be employed different ways; ſome may be diſperſed about the clumps, detached from the other plants, ſo placing ſtrong tall ſtakes for their ſupport, and they will have a ſingular effect among the other ſhrubs; others may be ſtationed near hardy trees and large ſhrubs, and ſuffered to climb about their ſtems, or interweave in their branches, and aſpire to

their tops or extremities, and ſpread about in their natural way, when they will have a beautiful effect in forming rural variety; ſome may alſo be employed to ornament naked or unſightly walls of high buildings, and ſome for decorating or forming rural arbours, where there is lattice, or any kind of open-work, for the branches to climb upon, which, in many of the ſorts, will ſhoot ten or fifteen feet in a ſummer; ſo that an arbour may be formed in one ſeaſon.

But for particulars of the different ſorts, and their culture, ſee their reſpective genera.

CLUTIA, *Clutia.*

This genus furniſhes three ſhrubby-ſucculent evergreen exotics for the green-houſe and ſtove, garniſhed with ſimple leaves, and greeniſh-white quinquepetalous flowers.

Claſs and order, *Dioecia Gynandria.*

*Characters.*] CALIX, male and female flowers on ſeparate plants, having cups compoſed of five large, oval, concave leaves. COROLLA, five heart-ſhaped, ſpreading, permanent petals, and at the bottom five nectariums placed circularly; and in the males five ſmall ones within the others. STAMINA, five horizontal filaments, ſituated in the middle of a ſtyle, and roundiſh verſatile antheræ. PISTILLUM, in the males no germen, but a long ſtaminiferous ſtyle; in the females a roundiſh germen, and three bifid ſtyles, and obtuſe ſtigmas. PERICARPIUM, a globular, ſix furrowed, trilocular capſule, and three ſeeds.

The two firſt ſpecies are green-houſe exotics.

[1]CLUTIA *Alaternoides.*

*Alaternoide Æthiopian Clutia.*] Clutia with a ſhrubby ſtem, branching laterally and erect, forming a head ſix or eight feet high; very narrow, ſpear-ſhaped, cloſe ſitting, greyiſh, alternate leaves; and from their axillas, ſolitary, ſmall, greeniſh-white, erect flowers.

[2]CLUTIA *Pulchella.*

*Purſlane-leafed Æthiopian Clutia.*] Clutia with a ſhrubby ſtem, branching from the ſides erectly ſix or eight feet high; oval, entire, ſea green, alternate leaves, on foot ſtalks; and ſmall greeniſh-white flowers along the ſides of the branches.

The following is a ſtove exotic.

[3]CLUTIA *Eluteria.*

*Eluteria, or Indian Clutia,*] Clutia with a ſhrubby ſtem, branching erectly five or ſix feet high; heart-ſhaped-lanceolate, pointed, foot-ſtalked, alternate leaves; and flowers in ſpikes at the ends of the branches.

The flowers of theſe three ſpecies are formed each of five ſmall petals, appearing in June, July, and Auguſt, but are not very ornamental; ſo that the merit of the ſhrubs is in their beautiful evergreen leaves.

The two firſt ſorts are green-houſe plants, and the other is of the ſtove, ſo muſt always be kept in pots of light rich earth; though they will all ſucceed in the open air in ſummer, and being always green, they are very ornamental at all ſeaſons.

Their propagation is by cuttings in ſpring or ſummer, planting them in pots of light earth, and plunge them in a hot-bed, they will readily emit roots, and muſt be tranſplanted into ſeparate pots.

CNEORUM, Widow-Wail.

There is but one ſpecies, a low evergreen ſhrub for the ſhrubbery, adorned with ſimple leaves, and tripetalous flowers.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX is monophyllous, tridented, and permanent. COROLLA, three oblong, ſpear-ſhaped, erect petals. STAMINA, three ſhort filaments, and ſmall antheræ. PISTILLUM, a blunt trigonous germen, firm ſtyle, and trifid ſtigma. PERICARPIUM, a globular, trilobate, trilocular, dry berry, and three ſeeds.

The ſpecies is,

CNEORUM *Triccocum.*

*Triccocous Cneorum.*] Cneorum with a ſhrubby hard ſtem, divided low into a branchy buſhy head two or three feet high, cloſely garniſhed with oblong-oval, cloſe-ſitting, ſtiff leaves, two inches long, and half an inch broad; and from their axillas, towards the ends of the branches, yellowiſh flowers, growing ſingly, ſucceeded by triccocous, three-ſeeded, baccaceous fruit.

It flowers from May till October, and affords plenty of ripe ſeed.

This is a very ornamental little evergreen for the fronts of the ſhrubbery clumps, though it is ſometimes retained as a green-houſe plant; but this is needleſs, unleſs merely for the ſake of variety, for it will proſper freely in the full air the year round, obſerving to allow it a dry ſoil, in which it will endure the rigours of ſevere winters, better than in rich moiſt ground.

The propagation of this ſhrub is by ſeeds and cuttings.

By ſeeds: ſow them in a bed of common earth half an inch deep in October, and moſt of the plants will riſe the ſpring following, the

the largeſt of which, in the ſpring after, may be thinned out, and planted in the nurſery-way, and in two or three years they will be ready for the ſhrubbery, &c.

By cuttings: this may be done in ſpring, cutting or ſlipping off ſome of the former year's ſhoots five or ſix inches long; plant them in a pot of good earth, and plunge them in a hot-bed, they will ſoon root and ſet to growing: young ſhoots, planted in a ſhady border in July, or early in Auguſt, will alſo grow.

COCHLEARIA, Spoonwort, or Scurvy-Graſs, and Horſe-Radiſh.

The plants are herbaceous and hardy, and of which there are two ſpecies that merit culture; one of them a fibrous-rooted biennial for medicine; the other a carrot-rooted perennial, valuable for its root as an eſculent, well known by the appellation of Horſe-Radiſh.

It may to ſome appear ſtrange to ſee Horſe-Radiſh retained as a ſpecies of Scurvy-Graſs, but its general characters certainly declare it of that genus.

Claſs and order, *Tetradynamia Siliculoſa.*

*Characters.*] CALIX, four oval concave leaves. COROLLA, four oval, ſpreading, cruciforme petals. STAMINA, four long, and two ſhort filaments, and obtuſe compreſſed antheræ. PISTILLUM, a heart-ſhaped germen, ſhort ſtyle, and obtuſe ſtigma. PERICARPIUM, a heart-ſhaped, gibbous, compreſſed, bilocular pod, affixed to the ſtyle, and eight ſeeds.

The ſpecies of our gardens are,

[1]COCHLEARIA *Officinalis.*

*Common Officinal Scurvy-Graſs.*] Cochlearia with a fibrous root, crowned by a cluſter of round ſucculent leaves, hollowed like a ſpoon, and amongſt them branchy ſtalks ten or twelve inches high, garniſhed with oblong ſinuated leaves, and at the ends of the branches cluſters of ſmall white flowers.

It flowers in April and May, ſucceeded by plenty of ſeeds in June.

[2]COCHLEARIA *Armoracia.*

*Armoracia, or Horſe-Radiſh.*] Cochlearia with a long, thick, perpendicular, white root, crowned by large, ſpear ſhaped, erect leaves; and between them an upright ſtalk, garniſhed with ſmall jagged leaves, and terminated by white flowers.

The firſt ſort, *Cochlearia Officinalis*, is a medical herb, and its virtue reſides in the leaves and ſtalks. It may be conſidered both as an annual and biennial, and its propagation is by ſeed annually in ſpring or autumn, in any ſituation, ſowing it on the ſurface, and rake it in, which, if ſown in autumn ſoon after it ripens, i. e. in July, or beginning of Auguſt, the plants will riſe ſoon after; thining them to three or four inches, and they will ſtand the winter, and be fit for uſe in ſpring.

The ſecond ſpecies, *Horſe-Radiſh*, is in much eſteem for its eatable root, which is uſed raw, ſcraped into fine ſhreds, and is either uſed alone as ſauce to fleſh meat, or incorporated in ſallads, and is alſo uſed for garniſh to diſhes, &c.

It is a very hardy plant, is perennial in root, and its nature of growth is—The bottom of the root generally reſolves itſelf into a thick, knotty, durable ſtool, at a certain depth in the ground, and from which ariſe ſeveral erect root-ſhoots, advancing perpendicularly to the ſurface of the earth, which, after having one or two years growth, acquire a ſubſtance of one or two inches thickneſs, and that being taken up for uſe, the ſtool remaining ſends up a freſh ſupply the year following; therefore, in the culture of this plant, it is neceſſary to plant the roots twelve or fifteen inches deep in the ground, to form ſtools that depth under the ſurface, that they may ſend up long, ſtrait, regular ſhoots, which, ariſing in ſpring, continue encreaſing in ſubſtance till September or October, when, in rich ground, they probably will be large enough for uſe, i. e. about an inch thick; but if they are much ſmaller, permit them to have another ſummer's growth, obſerving, when you take them up, to trench the ground open to the depth of the ſtool; ſo cutting off the young ſhoots cloſe to the place from whence they proceed, always leaving the old ſtools undiſturbed, and they will furniſh you with a freſh crop, as above, annually.

The propagation of this plant is by roots, cuttings of which, taken from the top an inch or two long, or even any part of the root cut into ſets that length, each having an eye or bud, will readily grow and become a plant.

But although any part of the root will thus readily grow, the beſt ſets for planting are cuttings taken from the top of the roots with the head or crown to them, either of the principal roots, or their off-ſets or ſide-ſhoots, as alſo the ſmall off-ſets ariſing immediately

from

from the ſtools; therefore, when intended to make a freſh plantation, it is proper, according as the roots are taken up occaſionally for uſe, to reſerve a quantity of the largeſt off-ſets, and lay them in the earth till wanted; then cut the tops off for planting two or three inches long; the tops of the main roots may alſo, when taken up, be cut off an inch or two long, and preſerved as above for the ſame purpoſe; but this latter is only practicable in private gardens; for, if the kitchen-gardeners were to cut off the tops of their marketable roots, it would render them unſaleable; ſo, in this caſe, recourſe is commonly had to the off-ſets above deſcribed.

The ſeaſon for planting them is any time in open weather from November till ſpring, though I ſhould rather prefer the month of February or beginning of March, eſpecially in wet or ſtubborn ground.

As to the ſoil proper for their culture, obſerve, that although the plants will grow in almoſt any ſoil and ſituation, yet to have long ſtrait roots of conſiderable ſubſtance, a rich, moderately-light, deep ſoil, in an open expoſure, ſhould, where poſſible, be choſen, and which ſhould be regularly trenched two moderate ſpades deep, well breaking all large clods, that nothing may obſtruct the perpendicular growth of the roots.

The method of planting is:—the ſets or cuttings are to be planted in rows two feet deep, nine inches diſtance in the lines, and each cutting placed twelve or fifteen inches deep, for the reaſon already hinted, and may either be planted by dibber, after the ground is dug, or they may be trenched in, placing them in the bottom of the trenches as you proceed in trenching. But, firſt, of planting by dibber, which is the method I prefer for general practice: the ground being dug a due depth, as before directed, and the ſurface laid level, then begin at one end, and ſtrain a line croſs-ways the ground, and having a long dibber, make holes therewith fifteen inches deep, and nine aſunder, and as you go on, drop one ſet or cutting in each hole, with the top or crown upright, ſtriking in the earth upon them; one row being thus planted, move the line two feet farther, and plant another in the ſame manner, and ſo proceed to the end. Next, with regard to the method of planting by trenching them in:—The ground is to be trenched in the uſual way, beginning therefore at one end of the piece, and open a trench two ſpades wide, and one deep, and dig the bottom; then by line ſet a row of cuttings along the middle of the bottom nine inches diſtance, thruſting them up to their tops in the earth, and then dig the next trench the ſame width and depth, turning the earth thereof into the firſt upon the row of plants, breaking all large clods, and level the top; then digging the bottom of this ſecond trench, plant another row of cuttings as above, covering them with the earth of a third trench; and in this manner proceed till the whole is planted, levelling the ſurface as you go on in a regular manner.

When the whole is planted in either of the above methods, the ground may be ſown with ſpinach and radiſhes, or any ſlight-rooting temporary crop, that comes off early in ſummer, by the time the Horſe-Radiſh appears, which, as they have to ſhoot quite from the bottom, they rarely make their appearance the firſt year before the middle of May, when all other crops muſt be cleared off, and the ground hoed to deſtroy weeds, and the leaves of the Radiſh will ſoon cover the ground, and no further care will be required till the roots are fit to take up for uſe.

In October following you may examine the roots; ſometimes they will make ſuch progreſs, as to be large enough for uſe; but if they, however, are not greatly wanted, they will be in excellent order by that time twelvemonth.

When the roots are to be taken up for uſe, begin at the firſt row, and open a trench two feet wide, and as deep as the ſtool or bottom of the roots, but without diſturbing them; then with your knife cut off all the ſhoots, large and ſmall, of each ſtool, cloſe and level to the place from which they ariſe, leaving the ſtool in the ground; and when you have taken up all the plants of the firſt trench, then proceed to the next row; open another trench, turning the earth into the firſt, and cut off all the ſhoots of this row as before; and in like manner continue taking up the whole, according as they are wanted, and the ſtools remaining undiſturbed, they will ſend up a freſh ſupply of ſhoots for another year's ſervice, and after theſe another; and in that manner they will furniſh a ſucceſſion for many years, obſerving to take up the crops of each year as above directed.

But I would obſerve, that after the firſt and ſecond year, the ſtools ſpread at bottom, and ſend up many ſmall ſhoots between, and in

in the rows; therefore, to encourage the principal ſhoots, all the ſmall ſpawn ſhould be annually drawn up in May and June.

It is likewiſe proper to remark, that although the ſtools of theſe roots will endure many years, they will in time become weak, or worn out, as alſo the ſoil; therefore, in ſix or ſeven years, more or leſs, when you perceive the ſhoots come weak and inconſiderable, prepare to make a freſh plantation in another part of the garden.

COCOS, Cocoa-Nut-tree.

There is but one ſpecies, an exotic tree for the hot houſe, of the palm tribe, having no branches, but very large, long, branch-like, winged leaves.

Claſs and order, *Monoecia Hexandria.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant, growing in a ſpadix, protruded from a general univalvular ſpatha, each flower of the ſpadix having a cup compoſed of three ſmall concave coloured leaves. COROLLA, each flower of the ſpadix compoſed of three petals. STAMINA, ſix filaments, and arrow-ſhaped antheræ. PISTILLUM, an oval germen, no ſtyle, but a trilobed ſtigma. PERICARPIUM, a very large, roundiſh, trigonous, leathery cover or drupe, incloſing a large, oval, hard nut, having three holes at the baſe.

The ſpecies is,

Cocos *Nucifera.*

*Nut-bearing Cocos, or Cocoa-nut-tree.*] Cocos with an upright, ſimple, branchleſs trunk, many feet high, garniſhed at top with large, branch-like, winged leaves, of many ſword-ſhaped lobes, folded back at the edges; and at top of the ſtem, long ſpadiceous bunches of flowers, ſucceeded by cluſters of very large, triangular, fibrous fruit, each containing a large oval nut, incloſing a white ſweet kernel, and a quantity of wholeſome milky liquor.

This tree is a native of India, where it obtains ſixty feet ſtature; and its branch-like leaves are often twelve or fifteen feet long, appearing like branches, there being no other.

It is retained here in our ſtoves as a curioſity, its large leaves effecting a ſingular appearance.

It is raiſed from the nuts, great quantities of which are annually brought to England by the Weſt-India ſhips; theſe, as ſoon as they arrive, are to be planted ſeparately in pots of rich earth, placing them ſide-ways, and directly plunge the pots over their rims in a bark-bed, and in ſix weeks they will germinate at the holes at the baſe, and will ſoon come up, giving frequent waterings, and continue them always in the ſtove, ſhifting them annually into larger pots, being careful at each removal to preſerve the ball of earth about their roots, and not to break the fibres.

COFFEA, Coffee-tree.

It conſiſts of one beautiful evergreen ſhrub for the hot-houſe, producing both flowers and fruit in England; and its fruit or berries is the Coffee.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is ſmall, four-parted, and placed on the germen. COROLLA is monopetalous, funnel-ſhaped, tubular below, plane and five-parted at top. STAMINA, five filaments placed in the tube of the corolla, and linear incumbent antheræ. PISTILLUM, a roundiſh germen, ſingle ſtyle, and two thick reflexed ſtigmas. PERICARPIUM, an oval umbilicated berry, having two hemiſpherical ſeeds.

The ſpecies is,

COFFEA *Arabica.*

*Arabian Coffee-tree.*] Coffea with an upright brown ſtem, branching by pairs oppoſite, ten or twelve feet high, each pair croſſing that immediately below it, and diminiſhing in length upward, garniſhed with large oblong-oval, waved, oppoſite leaves; and at the ſides of the branches, cloſe-ſitting cluſters of pure white quinquefid flowers, ſucceeded by oval berries, ripening to a blackiſh colour.

This is a very ornamental evergreen ſhrub, a native of Arabia Felix and Æthiopia, and requires the temperature of a hot-houſe in this country; ſo muſt always remain in pots of rich light earth, and reſide conſtantly in that department, where it will continue its verdure beautifully the year round, produce flowers and ripe berries, and effect an ornamental appearance at all ſeaſons, but more particularly in autumn and winter, when furniſhed with fruit.

It is raiſed from ſeed, i. e. the berries; and thoſe produced here in our ſtoves will grow; obſerving, that as they ſoon loſe their germinative property, it is eligible to ſow them as ſoon as poſſible after they ripen. Let them be ſown in pots of light rich earth half an inch deep, and plunge the pots in the bark-bed, giving light ſprinklings of water once a week, and in about a month the plants will appear, which, when three inches high, prick into ſeparate ſmall pots, give a little water, and plunge them again in the bark-bed,

and

and afford them ſhade from the ſun till they have taken root, repeating the waterings moderately as you ſhall ſee occaſion, and give them air in common with the other exotics of the ſame department.

This tree is alſo ſometimes propagated by layers and cuttings, which, however, emit roots rather reluctantly; but it is worth the trial, planting them in pots of good earth, and plunge them in the bark bed, ſupplying them duly with water and occaſional ſhade.

The general culture of this tree in this country is—it muſt remain continually in the ſtove, have water two or three times a week in ſummer, and about once a week in winter, and freſh air admitted in common with the other exotics of the hot-houſe; and as it advances in growth, allow it larger pots in proportion. Likewiſe, every year or two ſhift it into freſh earth, obſerving, at each time of removal, to trim off all matted roots on the outſide of the ball, as alſo part of the old earth; then, placing the plant in the pot, fill it up with freſh compoſt, none better than good light kitchen garden earth, and directly give water, and plunge them in the bark-bed.

Cleanlineſs is alſo eſſential in the culture of this ſhrub here in our ſtoves; therefore, when it has contracted much duſt or filth, let all the branches and leaves be well waſhed.

Likewiſe obſerve, that as it is frequently attacked by inſects, particular attention is neceſſary when theſe appear, to waſh and clean every branch and leaf one by one, which ſhould be repeated as often as the vermin make their appearance; but if they are very numerous, it is a ſign of ill health and weakneſs in the plant, and it proceeds chiefly from the root; therefore, in ſuch a caſe, it is adviſeable alſo to ſhift the plant into entire freſh earth, and plunge it in the bark-bed; and when it recovers its health and vigour, the inſects will diſappear.

COLCHICUM, *Colchicum*, or Meadow-Saffron.

This genus furniſhes a beautiful collection of bulbous-rooted, very low, flowery perennials for the borders, poſſeſſing the ſingular circumſtance of their leaves appearing at one time, and their flowers at another; the former riſing long and narrow from the root in ſpring, and decay in June; and the flowers, which are monopetalous, long, tubular, ſix-parted, and erect, riſe naked; alſo from the root in autumn, not more than four or five inches high.

Claſs and order, *Hexandria Trigynia.*

*Characters.*] CALIX none. COROLLA is monopetalous, formed into a long tube, riſing directly from the root, widening and divided above into ſix ſpear-ſhaped, oval, concave, erect ſegments. STAMINA, ſix awl-ſhaped filaments, and oblong, incumbent, quadrivalvular antheræ. PISTILLUM, a germen buried in the root, three long ſlender ſtyles, and reflexed channelled ſtigmas. PERICARPIUM, a trilobate, trilocular capſule, having many roundiſh ſeeds.

The ſpecies are,

COLCHICUM *Autumnale.*

*Common Autumnal Meadow Colchicum.*] Colchicum with an oblong-roundiſh, dark-brown, bulbous root; erect plane leaves ſix inches long, and one or two broad; and flowers ariſing without foot-ſtalks directly from the root, having an erect tube three or four inches in length, widening above, and divided into ſix oval ſegments, in colour different in different varieties.

*Varieties are*] Common Autumnal Colchicum with ſingle purple flowers—double purple flowers—many-flowered purple—variegated purple—with white ſingle and double flowers—many-flowered white—white and red flowers—roſe-coloured ſingle and double flowers—variegated roſe-coloured flowers—red flowers—red and white flowers—yellow flowers—with broad leaves—ſtriped leaves.

[2]COLCHICUM *Montanum.*

*Mountain Spaniſh Colchicum.*] Colchicum with an oblong, roundiſh, very dark coloured, bulbous root; long, narrow, ſpreading leaves; and reddiſh flowers, riſing without foot-ſtalks directly from the root, having a long tube divided into ſix narrow ſegments, and yellow ſtamina.

*Variety.*] Mountain Colchicum with ſtriped red flowers.

[3]COLCHICUM *Variegatum.*

*Variegated Checquered Eaſtern Colchicum.*] Colchicum with an oblong, flattiſh, bulbous root; broad, waved, ſpreading leaves; and large flowers, riſing without foot-ſtalks directly from the root, divided into ſix long erect ſegments, beautifully checquered with red, white, and crimſon.

*Varieties.*] Variegated checquered Colchicum with double flowers—with plane leaves, and ſingle and double checquered flowers

The firſt of theſe three ſpecies, *Colchicum Autumnale*, in its ſingle purple ſtate, grows wild in many of our rich meadows; but which,

which, and all its varieties, being ſingularly ornamental, is alſo common in many curious gardens.

All the ſpecies and reſpective varieties are hardy, and are pretty autumnal ornaments for the fronts of flower borders; their nature of growth is, they produce their leaves commonly in ſpring, though thoſe of the ſecond ſort often riſe the beginning of winter, and thoſe of all the ſorts continue their growth till June, then totally decay, and the root in a manner remains dormant till Auguſt or September, when the flowers burſt forth from it entirely naked, without foot-ſtalk, calix, or foliage, each flower conſiſting of one leaf, formed into a long erect tube, from three to five or ſix inches long, ſtanding on the root, and divided at top into ſix oval erect ſegments; the lower tubular part ſupply the place of a foot-ſtalk to the upper diviſions, and when the flowers fade, the ſeed veſſels form within the ground, and ſlowly raiſe themſelves among the green leaves the following ſpring, and the ſeeds ripen in May or June.

Theſe plants may either be planted in beds by themſelves, in rows nine inches aſunder, or may be diſperſed in the fronts of the different borders; obſerving, in either method, they ſhould be planted three inches deep: and the ſeaſon either for procuring roots to plant, or to tranſplant thoſe already in your poſſeſſion, from one part of the garden to another, or into freſh beds, &c. is when their leaves decay in ſummer; and the beſt time is from the beginning or middle of June until the beginning of Auguſt, after which time they will ſoon emit new fibres, and ſhould not be removed, nor thoſe already up be kept longer out of ground, if you would have them flower in perfection the ſame autumn.

They ſhould be removed every two or three years at leaſt, when the bulbs will be encreaſed into large bunches, ſo ſhould be taken up and ſeparated. See BULBOUS-ROOTS.

Moſt of theſe bulbs are ſo hardy, that they will flower as they accidentally lie out of ground; but this greatly weakens them.

*Propagation.*

Their propagation is by off-ſets of the bulbs, of which they are very prolific, which are to be taken up and divided at the decay of the leaf in ſummer, as above hinted, planting the whole again before the middle of Auguſt.

New varieties are alſo obtained from ſeed, which ſhould be ſown in boxes, or large pots, in autumn, covering it a quarter of an inch deep, and place them in a warm ſituation till ſpring, when the plants will appear, which ſhould have only the morning ſun during ſummer, giving water in dry weather; and in the ſecond ſummer, when their leaves decay, plant them out in beds to flower.

COLUTEA, Bladder-Sena.

It furniſhes hardy deciduous flowering ſhrubs, and a ſhrubby flowery perennial, all of them adorned with winged leaves of many pair of lobes, and butterfly-ſhaped flowers growing in cluſters, and are elegant furniture for the ſhrubbery.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, bell-ſhaped, five-parted at top, and permanent. COROLLA is papilionaceous, varying in figure in different ſpecies. STAMINA, ten filaments, one of them ſeparating from the reſt, and ſimple antheræ. PISTILLUM, an oblong compreſſed germen, a riſing ſtyle, and a linear bearded ſtigma. PERICARPIUM, a large ſwollen bladder-ſhaped unilocular pod, having kidney-ſhaped ſeeds.

The botaniſts allow of but two or three diſtinct ſpecies, but of which there are ſome curious varieties.

The ſpecies of our gardens are,

[1]COLUTEA *Arboreſcens.*

*Tree Colutea, or Common Bladder-Sena.*] Colutea with an upright, woody, whitiſh ſtem, branching laterally, and divided upward into a branchy head twelve or fourteen feet high, garniſhed with winged leaves of four or five pair of oval-obcordated lobes, terminated by an odd one; and from the ſides of the branches, numerous ſmall cluſters of pale yellow flowers, ſucceeded by large bladder-ſhaped pods.

Varieties of this are the two following.

*Pocock's Tree Colutea.*] Colutea with an upright, woody, whitiſh ſtem, branching ſix or ſeven feet high; winged leaves, of ſeveral pair of oval obcordated lobes, terminated by an odd one; and deep yellow flowers.

*Oriental Tree Colutea.*] Colutea with a woody ſtem, branching ſix or ſeven feet high; winged leaves of ſeveral pair of oval-obcordated lobes, ending in an odd one; and blood-coloured yellow-ſpotted flowers.

[2]COLUTEA *Fruteſcens.*

*Shrubby Æthiopian Scarlet Colutea.*] Colutea with a ſhrubby ſtem, branching from the ſides erectly four or five feet high; winged leaves of ten or twelve pair of oblong-oval, hoary, whitiſh lobes, terminated by an odd

one; and at the upper part of the branches, many ſmall bunches of ſcarlet flowers, ſucceeded by large ſwollen pods.

The flowers of all the ſorts are of the pea-bloom, or butterfly kind, conſiſting each of a ſtandard, two wings, and a keel. See PAPILIONACEA.

They are all hardy enough to ſucceed in the ſhrubbery, but the ſecond ſpecies requires a warm ſituation; they flower abundantly in June and July, ſucceeded by numerous pods, furniſhed with ripe ſeeds, from which all the ſorts may be raiſed plentifully in the common ground.

The firſt ſort and its two varieties are very ornamental, both in their beautiful pinnated foliage, and their numerous flowers, in June and July, as well as their bladder-ſhaped pods an inch or two long, which produce an agreeable variety in autumn; all of which are proper ornaments for any of the ſhrubbery plantations, as they proſper freely in any common ſoil and expoſure, in common with other hardy flowering ſhrubs.

The ſecond ſpecies is a moſt elegant plant, and flowers beautifully in June and July, but is rather of tender quality, being impatient of ſevere froſt; ſo ſhould have a ſheltered ſunny ſituation, and dry warm ſoil, and is proper alſo to retain ſome in pots, to move to ſhelter of a green houſe, or deep frame, in winter; obſerving, as the plants, at any rate, are apt to go off in two, three, or four years, a ſupply ſhould be raiſed every year or two from ſeed, which when ſown early in ſpring, the plants often flower the ſame year in Auguſt and September.

*Propagation of all the Sorts.*

The firſt ſort and varieties are raiſed abundantly from ſeed, ſown in February or March half an inch deep, in a bed of common earth, and the plants will riſe freely, and be fit to tranſplant in nurſery rows in ſpring following, and in two or three years will be ready for the ſhrubbery.

They alſo grow by layers, layed any time in autumn, winter, or ſpring.

The ſecond ſpecies, *Colutea Fruteſcens*, is alſo raiſed from ſeed, ſown half an inch deep in a warm border in March or April, and when the plants are three inches high, tranſplant them, ſome in a ſheltered border, and ſome in pots, to move under ſhelter the following winter. But if you would have the plants forwarder, or to flower the ſame year, ſow the ſeed in pots, and plunge them in a hot-bed early in March, it will forward them conſiderably, that the plants will probably flower in July or Auguſt.

COMPOSITUS *Flos*, Compound Flower, i. e. compoſed of numerous floſculi, or ſmall florets in the ſame calix, as in daiſy and ſunflower.

All Compound Flowers are aggregate. See AGGREGATUS.

A compound flower is defined to be formed of an aggregate, or union, of ſeveral diſtinct fructifications, or many ſmall florets, or leſſer flowers, within one common cup or calix, and each floret furniſhed with a proper fructification, either all hermaphrodites, or males and females, or hermaphrodites or males in the diſc or middle, and females in the radius or circumference, and all the hermaphrodites having each five ſtamina, and theſe always united by their antheræ or tops into a cylinder, through which paſſes the ſtyle, crowned by divided ſtigma, having both the diviſions or ſegments revolute, or rolled back, and each floret ſucceeded by a ſingle naked ſeed, which is either coronated with down, &c. as in dandelion; or the crown is wanting, as in ſunflower.

Examples of Compound Flowers, are daiſy, feverfew, marigold, ſunflower, aſter, chryſanthemum, hawk-weed, centaury, African marigold, dandelion, and many others; all of which are formed of many florets in one common cup, as above deſcribed.

All Compound Flowers, which are a numerous tribe, are of the claſs *Syngeneſia*. See CLASSIS.

The other general properties of a Compound Flower are,

The common or general calix is formed either of one ſeries of leaves, immediately ſurrounding the receptacle and floſcules or florets, or of a double ſeries, frequently a leſſer and a greater, and is ſometimes imbricated, i e. formed of many ſcales.

The leſſer flowers or florets that form the Compound Flower are univerſally monopetalous, i. e. of one petal, ſitting cloſe upon the receptacle, and are of different figures and ſizes in different genera; and under each floret is generally placed a ſingle ſeed.

The compound flowers have different appellations, according to the form, or figure, and ſituation of the florets of which it is compoſed.

They

They are generally diſtinguiſhed by the following appellations.

Tubular Compound Flower, (*tubuloſus*, or of hollow florets); all the florets that compoſe the flower are tubular and funnel ſhaped, that is, hollow almoſt from bottom to top, and divided into five ſpreading parts at the brim, and which kind of florets, when they compoſe entirely the whole Compound Flowers, are moſtly all hermaphrodites, having each five ſtamina and a ſtyle; though there are tubular male and female florets, common to ſome genera; alſo hollow neutral florets.

Ligulated Compound Flower, (*ligulatus*, flat or ſtrap-ſhaped florets); the florets that compoſe the flower are all plane, flat, and expanded, and reſemble a ſtrap, fillet, or tongue, and are either entire at top, or divided into three or five parts, and which kind of florets, when they form entirely any compound flower, are commonly all hermaphrodites, and have each its five ſtamina, ſtyle, and naked ſeed, as in hawkweed, dandelion, and many other genera; but there are alſo ligulate male and female florets, ſometimes in the ſame or different flowers.

Radiated Compound Flower, (*radiatus* or *radius*, a radiated margin or circumference); having one, two, or more ſeries of long flat florets placed round the margin or outward part, in form of a ray, or reſembling the rays proceeding from the body of the ſun, as in ſunflower; and the diſc (*diſcus*), or central part, is formed by numerous ſmall tubular florets, exemplified alſo in ſunflower, marigold, &c. In moſt radiated compound flowers, the radius is generally formed of ligulated or plane florets, as in ſunflower and marigold juſt mentioned, and are commonly all females or neuterals; and the tubular florets in the diſc are generally all hermaphrodites or males; but in ſome genera the radius is formed by long tubular florets, unlike thoſe in the centre, as in centaury or blue-bottle; and in ſome the florets in the radius are naked, that is, without petals altogether.

It is moſtly to be obſerved, that both tubular and flat florets, in all Compound Flowers that are not radiated, are generally all hermaphrodite.

And in radiated Compound Flowers, the florets which occupy or form the diſc, are, for the general part, all hermaphrodite or male; and the ſemi, or other florets, that conſtitute the rays, are moſt commonly females or neutrals.

Neutral florets are ſuch as want both ſtamina and ſtyle, and are of no ſex, or neuter.

Naked florets are ſuch that have no petal or corolla.

But Compound Flowers are conſtituted ſeveral ways; as,

Tubular hermaphrodite florets, both in the diſc and radius.

Tubular hermaphrodite florets in the diſc, and tubular females in the radius.

Tubular hermaphrodites in the diſc, and tubular neutrals in the ray.

Tubular hermaphrodites in the diſc, and ligulate hermaphrodites in the radius.

Tubular hermaphrodites in the diſc, and ligulated females in the radius.

Tubular hermaphrodites in the diſc, and ligulated neutrals in the ray.

Tubular hermaphrodites in the diſc, and naked females in the radius.

Tubular male florets in the diſc, and naked females in the rays.

Ligulated hermaphrodites both in the diſc and radius.

As to the number of florets in a Compound Flower, they are generally very numerous and indeterminate.

In ſome genera the florets of the Compound Flower have ſmall diſtinct cups within the larger, and belong to the fifth order of the claſs *Syngeneſia*.

### *Of Double Compound Flowers.*

Plenitude or doubleneſs in Compound Flowers is effected different ways.

As, for example, radiated Compound Flowers, which generally have plane florets in the margin, and tubulars in the diſc, is rendered double two different ways; that is, the plenitude may either be effected by an encreaſe of the radius, and an almoſt total excluſion of the tubular florets in the diſc, or is effected by an elongation of the hollow florets in the centre, and a leſs profound diviſion of their brims. In the firſt mode of impletion, which is termed impletion by the radius, it is evident that a radiated flower, rendered double by the radius, will be either almoſt entirely female florets, as in feverfew and African marigold; or of neutral florets, as in ſunflower: and in the ſecond mode of impletion, termed impletion by the diſc, the florets of that part are extended to a great length, and thoſe of the radius, though they ſometimes remain unchanged, moſt commonly adopt the figure of thoſe of the diſc, without, how-

ever, ſuffering any alteration in the point of ſex; daiſy, feverfew, and African marigold, exhibit inſtances of this, as well as the former mode of impletion.

The impletion of tubular Compound Flowers ſeem to obſerve the ſame rule as that of the radiated flowers juſt delivered.

COMPOSTS. In gardening, Compoſts are compounds or mixtures of ſeveral earths, or earthy ſubſtances, and dungs, either for the improvement of the general ſoil of a garden, or of that for ſome particular plants.

Almoſt every plant in nature may be ſaid to have ſome particular favourite ſoil, and yet there is hardly any plant or tree but what will proſper in common garden earth; and even the moſt delicate plants of our green-houſes, ſtoves, and hot-beds, are found to ſucceed in common rich light mould, of the quality of that of a good kitchen garden; ſo that none need be at any great loſs on the conſideration of Compoſts. I would obſerve, however, that many kinds of plants may be farther improved by Compoſts adapted to the ſoil of their natural growth; but, on the other hand, would be underſtood to mean, that only a few different Compoſts is neceſſary for all the known plants in the world, which we can affirm for the ſatisfaction of the unexperienced, and not perplex them with tedious directions in every genus, for preparing expenſive and troubleſome Compoſts for every ſpecies thereof, which is altogether unneceſſary.

But there are ſome authors on gardening particularly profuſe and tedious in the article of Compoſts, frequently preſcribing a different one for almoſt every different plant, which too, are often of ſo ſtrange compoſition, and ſeem loaded with ſuch inconveniencies, trouble, and expence, in their preparation, as is ſufficient to diſhearten the unexperienced from attempting any thing in the vegetable world; as, for example, in Hill's works we may ſee directions for two or three hundred different Compoſts, and, as juſt obſerved, moſt of them too of ſuch uncommon compoſition, of ſo many different ſtrange ingredients, as to be conſiderably beyond the limits of general practice; nor would there be any end of the trouble and expence, which, after all, would be unneceſſary, and of no more ſervice to the plants than they might receive from a few well-prepared Compoſts of more practicable ſtructure, or even from common garden earth.

I therefore have found ſuch a multiplicity of compoſition entirely unneceſſary and perplexing, becauſe it is well known to obſervant practitioners, that a ſoil proper for every plant may be imitated in three or four principal Compoſts.

As, for inſtance, a rich moderately light Compoſt, of the texture of kitchen-garden earth, is agreeable to moſt plants. A looſe light Compoſt for ſome particular plants; a dry, ſandy, rubbiſhy, Compoſt for others, ſuch as moſt of the ſucculent tribe; and a loamy fattiſh Compoſt, of a pliable mouldery temperature, is particularly well adapted to moſt ſorts of trees and ſhrubs, and indeed to moſt plants that are not ſucculent.

But prepared Compoſts are principally in practice for plants in pots, and for ſome curious flowers in beds, and tender plants in hot-beds, &c.

In reſpect, however, to Compoſts, for the amendment of the general ſoils of a garden, ſeveral ſpecies of earthy ſubſtances may be employed, according as the quality of natural ſoil ſhall require; as, for inſtance, if the natural ſoil is of a very light, looſe, or ſandy quality, it may be aſſiſted occaſionally by the addition of heavy ſubſtances, ſuch as loam, and any kind of fattiſh earth, mud of ponds and ditches, with plenty of rotten dung; on the other hand, heavy, clayey, and all ſtubborn ſoils, may be meliorated by light Compoſts, i. e. any light ſandy earth, drift and ſea-ſand, the ſhovellings of turnpike-roads, the cleanſing of ſtreets, all kinds of aſhes, rotten tanner's-bark, rotten wood and ſaw duſt, and other ſimilar light opening materials that can be moſt conveniently obtained, adding to any, or all of them, a convenient portion of dung.

As to Compoſts for particular curious plants, to be preſerved in pots or tubs, beds, &c. the following are in practice.

One principal Compoſt in practice is, freſh or maiden earth from a paſture-ground, that is, of a light, but fattiſh mouldery temperature, and if it inclines to loam of a pliable texture, it will be an advantage; however, of any fat pliable paſture earth, take the top ſpit turf and all, and to which add about one third or fourth part of thoroughly rotten dung, and lay the whole in a long heap or ridge a yard high, in a ſituation expoſed to the ſun and air, to lie a year, turning it over ſeveral times, that the whole may be converted to mould, and the parts properly incorporated; and this will be found to anſwer almoſt every purpoſe

purpoſe of vegetation. But in default of good paſture earth, which is ſometimes inconvenient to be obtained, a quantity of good garden mould, of the above quality will anſwer very well; but more particularly that which has been well cultivated by proper manure, which may at all times be procured from the quarters of the kitchen garden: add thereto one third or fourth part of rotten dung, none better than that of old hot-beds; and if the mould is rather of a ſtiff nature, add alſo about a fourth part of ſea, or driſt ſand, or, for want of theſe, aſhes, or rotten tan, &c. caſting the whole in an heap, to lie five or ſix months, but if a year the better, ſtirring it over ſeveral times, as above directed.

Another Compoſt in uſe is, that for plants that particularly require a more light looſe ſoil; a Compoſt may be formed of one half good light paſture mould, or that of a garden, and about one third part of ſand, and another of rotten dung, forming the whole in a heap as above.

For plants that require a ſoft looſe rich earth, uſe for Compoſt good light rich earth of a garden or paſture, rotten tanner's bark, or rotten earthy wood, ſaw-duſt, tree leaves, rotten dung, and a ſmall portion of ſand.

For plants that delight in dry rubbiſhy ſoils, as the ſucculent tribe, form a Compoſt of one half of perfectly light garden or paſture mould, and one half of ſand or road ſoil, and a little ſcreened lime rubbiſh, laying the whole in a heap for a year, and turn it four or five times; which Compoſt may be made lighter or heavier, according as the plants are more or leſs ſucculent.

A loamy Compoſt, as already hinted, is a favourite ſoil of numbers of plants; that is, though moſt plants will flouriſh in any kind of good earth, or the Compoſts before-mentioned, yet that of a light, warm, loamy temperature, is found to improve the culture of almoſt all ſorts of plants, but more particularly all the tree and ſhrub kind; this Compoſt is thus prepared; maiden or freſh loamy earth from a common, or any dry paſture-ground, where the ſoil is of a ſoft and moderately light pliable nature (ſee LOAM), taking the uppermoſt ſpit, ſward and all, chopping it to bits, and add thereto rotten dung, as before directed, which, after lying in a ridge or heap twelve or fifteen months to rot the ſward, and by frequent turnings over to break the clumps, and mix the parts, will be excellent for uſe; when, if neceſſary, it may either be made lighter by the addition of ſome of the fore-mentioned light materials, or made heavier by a mixture of fat garden earth, according as the nature of particular plants ſhall require, which will be always hinted in the culture of the reſpective articles, whether in pots, beds, or borders.

The floriſts are generally curious in their compoſitions for their fine prize flowers; the following are their auricula and hyacinth Compoſts, but which will alſo anſwer for almoſt all other curious flowers.

For auriculas, the favourite Compoſt is, light earth from a paſture ground, the top ſpit with the ſward, and neats dung, of each an equal portion, and about half the quantity of driſt or ſea-ſand, and, when it can be had, a little rotten willow earth, or any rotten earthy wood, or old rotten tan or ſaw-duſt, forming the whole in an heap for a year, turning it over ſeveral times at proper intervals.

This Compoſt is alſo proper for many other curious flower plants, ſuch as the fine carnations, curious ranunculas, and anemonies; and for which, to make it go farther, you may add a quantity of good garden mould; obſerving, however, that though theſe flowers often excel in the above Compoſt, yet I have obſerved them flower almoſt equally well in common rich light garden earth.

For the hyacinth, the favourite Compoſt is different from the above, though that will anſwer tolerably well, as will alſo ſome of the other light Compoſts, and they even often proſper well in good garden earth; however, curious floriſts, to blow that delightful flower in its higheſt perfection, often uſe the following Compoſt—Neats dung and driſt ſand, of each an equal portion, and half the quantity of old rotten tan, and where it can be eaſily procured, the ſame portion of rotten leaves of trees, or, in lieu thereof, add a little more rotten bark, and a little very light earth from a paſture or garden; let the whole be mixed in a heap, to lie at leaſt a year, giving it frequent turnings; but if it remains in the heap eighteen months, or two years, it will be an advantage.

Of one or other of all the above Compoſts you ſuit all ſorts of plants ſufficiently, of which directions are given in the culture of all the reſpective articles; and any of the ſorts of Compoſt may always, upon occaſion, be eked out by an addition of garden earth, in proportion to the intended temperature of each reſpective Compoſt.

But where any particular Compoſt is neceſſary,

ceſſary, it is exhibited in treating of the culture of the reſpective articles.

In all Compoſts where ſand is neceſſary, ſea or driſt-ſand is to be preferred, and that which is dug out of pits is the moſt improper of all; therefore, where ſea-ſand cannot be eaſily obtained, which is rather the beſt, always chuſe driſt-ſand, or that taken near the ſurface.

Likewiſe in Compoſts where rotten earthy wood is requiſite, that of old rotten willow trees, or any other that can be had, will do; or, in default thereof, old rotten tanner's bark may be ſubſtituted, and is a very proper ingredient; alſo all ſorts of wood ſaw-duſt may be uſed.

In uſing garden mould occaſionally for compoſitions, the places of the quarters from whence it is taken, may readily be made good by a due ſupply of manure, and the emptyings of pots of old earth, and old flower-beds, &c. which being wrought up together with the natural ſoil, will be excellent for the growth of kitchen vegetables.

All Compoſts ſhould be formed in an open expoſure, free to the ſun, air, rains, froſts, &c. to meliorate and fertilize the ſoils; and the ingredients ſhould be formed in an heap, not in a large and high one, but rather extended in length like a ridge, about a yard or four feet thick, ſo that the rays of the ſun may penetrate through it: once every two or three months, at leaſt, it ought to be turned over, and the bottom thrown to the top, that all the parts may be well mixed, and equally participate of the influence of the ſun and elements; this is ſo eſſential, that if the heap is not thus expoſed, the Compoſt would be far from effecting the propoſed advantage to the plants, and would to many ſorts rather prove detrimental, that it would be more eligible to uſe common garden mould immediately from a well-cultivated border or quarter.

It is neceſſary that all Compoſts for plants in pots, tubs, &c. alſo for all tender plants in hot-beds and flower-beds, ſhould remain a year in the heap or ridge before it is uſed, eſpecially thoſe Compoſts formed of freſh earth and other new materials, which ſhould always have a ſummer's ſun and winter's froſt, and frequent ſtirring, for the whole ſhould be perfectly meliorated, and converted to a pure mould.

When the Compoſts are to be uſed, it is not adviſeable to ſcreen them, except for ſome particular purpoſes, which are hinted in different parts of the work; ſo that, for general uſes, the ſoil ſhould only be broken fine with the ſpade and hands, for, when fine ſcreened or ſifted, it becomes too compact for the roots of plants.

The term *maiden* or *virgin* earth, often mentioned for Compoſts, ſignifies that of any common, or other paſture ground, that have never been ploughed for the production of other crops, or, at leaſt, that have been a long time in paſture.

CONIFERÆ, Coniferous, or Cone-bearing; plants which bear that kind of fruit or ſeed-veſſel, called a Cone. See CONUS and STROBILUS.

The plants of this tribe are moſtly of the tree and ſhrub kind, and retain their leaves all the year, except ſome ſorts of larch, which loſe their leaves during the winter.

The principal genera of the Coniferous tribe are, the *pinus*, or pine-tree, including fir, larch, and cedar of Lebanon—the *cupreſſus*, cypreſs-tree—*Thuja*, arbor-vitæ—*ephedra*, ſhrubby horſe-tail—*juniperus*, juniper-tree, including ſavin, and ſeveral ſpecies of cedars. The height of ſome ſpecies of *juniperus* do not exceed two feet, that of ſome ſpecies of *pinus* approach to a hundred; their form is generally conical, and extremely beautiful, from the diſpoſition of their branches, which ſurround and cover the ſtem even to the root, and extend themſelves horizontally and circularly, like ſo many rays.

Moſt of the Coniferous trees are reſinous, or gummy; theſe gums have a bitter taſte, but very agreeable ſmell, and it is ſaid, plantations of them are exceeding wholeſome, by meliorating the air by their balſamic and aromatic exhalations, beſides being beautiful to behold.

From the larch-tree is extracted what we erroneouſly call Venice turpentine; from the wild pine, or pineaſter, is extracted the common turpentine, and from which is diſtilled the oil of that name; the dregs of the diſtillation is the common roſin: the pitch-tree, a ſort of fir, produces the ſubſtance from whence it derives the name. The branches of the black and white ſpruce-firs are uſed by the Americans in making their ſpruce-beer; the leaves of the common ſavin are uſed by farriers for deſtroying worms in horſes. A decoction in milk of the ſeeds of pineaſter, or of the extremities of the branches pulled in ſpring, is ſaid, with a proper regimen, to cure the moſt confirmed and inveterate ſcurvy.

All

All the ſorts are hardy and valuable plants in ornamental gardening, and many of them moſt valuable timber trees, particularly the genus *pinus*; none are more ornamental when growing, or turn to more profit when felled, for they arrive to great height and magnitude, and, as timber, are ſuperior for moſt kinds of buildings, and moſt excellent for maſts of ſhips.

The timber of the horizontal cypreſs is ſaid to reſiſt worms, moths, and all putrefaction, and to laſt many centuries; the doors of St. Peter's church at Rome were originally of this material, which, after laſting eleven hundred years, diſcovered not the leaſt tendency to corruption.

But for the culture, and other particulars of the Coniferous trees, ſee their reſpective genera.

CONVALLARIA, Conval-Lily, or Lily of the Valley, and Solomon's-Seal.

This genus conſiſts of hardy, herbaceous, flowery perennials, producing annual ſtalks from ſix inches to a yard in ſtature, adorned with oblong ribbed leaves, and monopetalous, ſmall, bell-ſhaped flowers, and are eligible furniture for the pleaſure-ground.

Claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX, none. COROLLA, monopetalous, bell-ſhaped, ſix-parted, and ſpreading at the brim. STAMINA, ſix filaments inſerted into the corolla, and erect antheræ. PISTILLUM, a globular germen, ſlender ſtyle, and obtuſe trigonous ſtigma. PERICARPIUM, a round trilocular berry, and ſingle ſeed.

The ſpecies of our gardens are,

[1]CONVALLARIA *Majalis*.

*Lily of the Valley, or May Lily.*] Convallaria with a fibrous creeping white root, crowned by oblong, erect, longitudinally-veined leaves, in pairs, five or ſix inches long, and one or two broad, and among them naked flower-ſtalks half a foot high, garniſhed with drooping white flowers, ranged in a ſingle ſeries on one ſide the ſtalk.

*Varieties.*] Lily of the Valley with ſingle white flowers—double white flowers—red flowers—purple and white ſtriped flowers—double purple and white flowers.

This ſpecies and varieties grow naturally in woods and ſhady places, in many parts of Britain, and other parts of Europe; but all of them poſſeſs great merit as flower-plants for ſhady borders, and the compartments of wilderneſs works, and the like, though they will ſucceed any where; and thoſe of the double and ſtriped kinds, particularly, are very beautiful.

[2]CONVALLARIA *Polygonatum*.

*Polygonatum, or Common Solomon's-Seal.*] Convallaria with a thick, knotty, fleſhy, fibrated, white root; upright, two-edged, firm ſtalks, two feet high, garniſhed with oblong-oval, ribbed, alternate leaves, their baſe embracing the ſtalk; and from their axillas, ſhort divided foot-ſtalks, each ſupporting one drooping white flower.

*Varieties.*] Common Solomon's-Seal with ſingle white flowers—double white flowers—ſweet ſcented white flowers—with purple ſtalks and white flowers.

This and varieties, as well as an ornamental plant in gardens, are of medical property, and its root is the part chiefly uſed, being frequently applied as a poultice to green wounds and bruiſes, and a decoction of the plant cures the itch.

[3]CONVALLARIA *Multiflora*.

*Multiflorous Solomon's-Seal.*] Convallaria with a thick, jointed, fibrated, white root; upright taper ſtalks near a yard high, garniſhed with broad, oblong-oval, alternate leaves, embracing the ſtalks with their baſe; and from their axillas, ſhort foot-ſtalks, ſupporting many greeniſh-white flowers.

*Varieties.*] Large Broad-leaved Multiflorous Solomon's-Seal with ſingle and double flowers—Dwarf Multiflorous Solomon's-Seal with ſtriped leaves.

[4]CONVALLARIA *Racemoſa*.

*Racemous-flowered Solomon's-Seal.*] Convallaria with a thick, knotty, fibrated root; upright ſtalks two feet high; oblong, pointed, ribbed, cloſe-fitting, alternate leaves; and the ſtalks terminated by racemous ſpikes of greeniſh-white flowers.

[5]CONVALLARIA *Verticillata*.

*Verticillated Narrow-leaved Solomon's-Seal.*] Convallaria with a thick, jointed, fibrated, white root; upright angular ſtalks two feet high; long, narrow, ſmooth leaves, in a verticillus or whirl round the ſtalks; and from the places of the leaves, ſhort foot-ſtalks, each ſupporting four or five ſmall whitiſh flowers.

The flowers of all theſe ſpecies are monopetalous, bell, or funnel-ſhaped, rather ſmall, and divided at the brim into ſix ſpreading ſegments, appearing in May and June, ſucceeded by round berries, furniſhed with ripe ſeeds in autumn.

They are all perennial in root, but the ſtalks and

and leaves are annual, riſing in ſpring, and periſh in autumn.

All the ſorts are hardy, and delight in ſhady places, ſo are well calculated as ornamental furniture for the borders of wood-walks, wilderneſs-quarters, and ſhady borders, where they will appear very ornamental both in their ſingular growth, foliage, and flowers, but all the ſorts will alſo grow in almoſt any ſituation, and multiply exceedingly by their creeping roots; and all the culture they require is, to have the ground dug between them annually, in common with the other plants, and to cut down their decayed ſtalks, and every three or four years to reduce their roots within due compaſs.

*Propagation.*

The propagation of all the ſorts is effected abundantly by dividing or ſlipping their roots any time from autumn till ſpring, though thoſe divided and planted out in autumn will flower ſtrong the following ſummer; the ſlips may be planted at once where they are always to remain, and they need not be removed oftener than every three or four years, when, if they are greatly encreaſed, it is proper to reduce them within due bounds.

CONVOLVULUS, *Convolvulus*, Bind-weed, or Bear-bind.

This genus compriſes many herbaceous twining and trailing plants, annuals and perennials, of which there are ſome of very flowery growth, and proper ornaments for the pleaſure-ground, and one or two for the green-houſe, all of them adorned principally with ſpear and heart-ſhaped leaves, and large open bell-ſhaped flowers.

This genus derives the name, *Convolvulus*, from *convolvendo*, i. e. rolling round, or twining about, as moſt of the plants wind and aſcend ſpirally round any ſupport.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, oval, five-parted at top, and permanent. COROLLA is monopetalous, large, bell-ſhaped, and ſpreading. STAMINA, five ſhort filaments, and compreſſed antheræ. PISTILLUM, a roundiſh germen, ſlender ſtyle, and two broad oblong ſtigmas. PERICARPIUM, a roundiſh capſule, having ſeveral roundiſh ſeeds.

There are upwards of thirty ſpecies, but not a quarter of them have merit in gardening, and ſome are common and very troubleſome weeds, ſuch as the Trailing Field Bind-weed, and the Large Volubilate White Bear-bind, both of which are ſpecies of *Convolvulus*; the latter, in particular, is often very troubleſome in gardens in ſummer, by its winding ſtalks, which twine about any thing they encounter, either along the ſurface of the earth, or aſcend ſpirally about tall plants or trees ten or fifteen feet high.

The ſpecies of this genus, therefore, that merit culture, are principally for ornamental purpoſes; and the following are the moſt material ſpecies of our gardens.

The firſt three are hardy herbaceous annuals.

[1]CONVOLVULUS *Tricolor.*

*Tricolor Convolvulus, commonly called Convolvulus Minor.*] Convolvulus with proſtrate branchy ſtalks two feet long, trailing on the ground, garniſhed with ſpear-ſhaped-oval, cloſe-ſitting leaves; and at their axillas, long foot-ſtalks, each ſupporting one large, tricoloured flower, blue, having a white and yellow flower.

*Varieties.*] Convolvulus Minor with blue flowers, having white bottoms—with white flowers—variegated blue and white flowers.

This ſpecies and varieties are very floriferous annuals; the ſtalks generally proſtrate themſelves along the ground, without any twining or climbing property, ſpreading their branches every way, flowering at every joint from June till September.

[2]CONVOLVULUS *Purpurea.*

*Purple Convolvulus Major.*] Convolvulus with twining, ſpirally aſcending ſtalks and branches, winding about ſupport ſix or eight feet high, adorned with roundiſh, heart-formed, entire leaves; and from the ſides, erect foot-ſtalks, ſupporting large open purple-coloured flowers.

*Varieties.*] Convolvulus Major with deep purple flowers—red flowers—blue flowers—white flowers.

Theſe varieties are very flowery and beautiful annuals, and if their ſtalks have ſupport to climb upon, they will flower at every joint from July till October, ſucceeded by abundance of ripe ſeed.

[3]CONVOLVULUS *Nil.*

*Anil, or Deep Blue Convolvulus Major.*] Convolvulus with twining ſtalks and branches, mounting about ſupport ſix or eight feet high, garniſhed with heart-ſhaped, three-lobed, hairy leaves, and long axillary foot-ſtalks, each ſupporting two large deep blue flowers.

This is an exceeding beautiful annual, requires ſupport to climb upon, and will exhibit a fine bloom from Auguſt till October.

The

The two following are ſhrubby perennials of the green-houſe.

[4]CONVOLVULUS *Canarienſis.*

*Canary Evergreen Convolvulus.*] Convolvulus with twining, woody, perennial ſtalks and branches, winding about ſupport twenty feet high, garniſhed with heart-ſhaped oblong, downy, evergreen leaves, and axillary foot-ſtalks, each ſupporting ſeveral purpliſh flowers.

[5]CONVOLVULUS *Cneorum.*

*Cneorum Album, or Silvery Convolvulus.*] Convolvulus with upright, ſhrubby, perennial ſtalks, branchy, and a yard high, cloſely garniſhed on every ſide with ſpear-ſhaped, downy, ſilvery leaves; and at the ends of the branches, cluſtery heads of reddiſh flowers.

The flowers of all theſe ſpecies are monopetalous, bell-ſhaped, large, and ſpreading, appearing in June, July, Auguſt, and September, are very elegant; and although each flower is but of one day's duration, the annual ſorts exhibit a daily and plentiful ſucceſſion till killed by the froſt, and ripen abundance of ſeeds.

They are all natives of diſtant countries, but have long been inhabitants of our gardens as plants of ornament.

All the annual kinds are hardy, and are beautiful furniture for the pleaſure-ground; will proſper in any common ſoil, and are proper both for borders and the vacant ſpaces in the fronts of the moſt conſpicuous ſhrubbery-clumps; and they all riſe freely from ſeed in the full ground, which may be ſown where they are to remain to flower; obſerving, that the *Convolvulus Tricolor*, or *Minor*, may either be ſuffered to trail upon the ground, according to its natural growth, or may be tied up to ſticks: but the other two annual ſpecies, and their varieties, being of the voluble or twining running kind, muſt have tall ſticks to climb upon, on which they will naturally twine themſelves ſeveral feet high, flowering all the way, and appear very ornamental.

The propagation of all theſe annual kinds is by ſowing the ſeed in March or April, in patches, in the places where they are to flower; in each patch ſow four or five ſeeds half an inch deep, and when the plants are an inch or two high, thin them, leaving but two or three of the beſt in each patch, (ſee ANNUAL PLANTS) managing them afterwards as above directed.

The two perennial ſpecies are tender, but elegant furniture for the green-houſe collection, and well worth the attention of every one poſſeſſed of the conveniencies for preſerving them during winter.

Let them be kept in pots of rich earth, and managed as *geraniums*, and myrtles, &c. See GREEN-HOUSE PLANTS.

The propagation of theſe two ſorts here is commonly by layers in the ſpring, which take root freely in three or four months; cuttings of the young ſhoots alſo grow freely in a ſhady border in May, June, and July; ſuckers from the root alſo make good plants.

Of this genus, the two following perennials, Bindweed, and Bearbind, before hinted, are well-known troubleſome weeds; but as they produce many elegant flowers, ſome for variety preſerve here and there patches of them for flowering.

Their titles, &c. are,

[6]CONVOLVULUS *Arvenſis.*

*Field Perennial Convolvulus, or Bindweed.*] Convolvulus with creeping and deeply penetrating, ſmall, fibrey, tough roots; many weak trailing and twining ſtalks, two or three feet long, garniſhed with ſmall, triangular, arrow-pointed leaves, the baſe pointed at both ſides; and at all the joints, a ſingle flower, on each foot-ſtalk, of different colours in different varieties.

*Varieties.*] Field Perennial Convolvulus with white flowers—roſe-coloured flowers—roſe and white ſtriped flowers—white and purple flowers—white and purple ſtriped flowers—purple white-rayed flowers.

All theſe varieties grow wild in great abundance on the ſides of banks and dry gravelly ſoils, where they exhibit a profuſion of flowers; but if ſome patches are intended for the garden by way of variety, great care is requiſite to keep their roots within due compaſs, for they creep far, and their ſtalks over-run whatever they grow near, and often riſe naturally in gardens, proving moſt troubleſome weeds, difficult to eradicate, for the roots run deep, and are ſo very tough, that gardeners in wrath often call them the devil's guts.

The roots are perennial, and the ſtalks riſe in ſpring, and die to the root in autumn.

[7]CONVOLVULUS *Sepium.*

*Hedge Perennial Convolvulus, or Great White Bearbind*] Convolvulus with long, creeping, thick, fleſhy, white roots, ſending up annually many twining ſtalks, winding round ſupport ten or fifteen feet high, garniſhed with large, roundiſh and oblong, arrow-pointed leaves, divided at the baſe; and long foot-ſtalks from the joints of the branches, each ſupporting one large, bell-ſhaped, pure white flower.

*Varieties.*] Large purple flowers—large purple-ſtriped flowers.

This ſpecies grows wild in hedges and gardens, have perennial roots, and annual ſtalks, aſcending ſpirally round the neighbouring plants, buſhes, hedges, and trees, producing many fair flowers; but if ſome patches are deſigned as climbers in wilderneſs-works, or ſhrubberies, for variety, they ſhould be placed detached from all other plants and trees, and fix long ſtout ſtakes for their ſtalks to twine upon, and keep their roots within due bounds, for they often riſe naturally in gardens, and prove moſt troubleſome weeds to the gardener, having very creeping roots, that multiply greatly, run deep in the ground, and the leaſt bit will grow and ſend up ſtalks that overrun and twine round every thing in their progreſs; therefore, in digging the ground, every bit that appears ſhould be carefully picked out, and in ſummer the ſtalks ſhould be conſtantly pulled up, which will alſo contribute conſiderably to the deſtruction of the roots.

The following perennial of the ſame genus is alſo cultivated in ſome gardens for variety.

8 CONVOLVULUS *Batatas.*

*Batatas, or Spaniſh-Potatoe.*] Convolvulus with large, oblong, tuberous, white, eatable roots; trailing ſtalks three or four feet long; heart-ſhaped-angular leaves; and large, bell-ſhaped, white flowers; and the ſtalks rooting at the joints, and form large tubers.

This is a native of Spain and Portugal, where the roots grow very long and large, reſembling large white kidney-potatoes; they do not, however, acquire perfection in England, but a few of the roots are annually imported from the above countries for curioſity, and we may often ſee them lying in the great fruiterer's ſhops in London.

If intended to have a few plants for variety, plant the roots, either whole or divided, in a warm border, in March or April, where they will ſend up ſtalks, and flower in autumn; but to have them in greater perfection, plant the roots in a ſlender hot-bed, covered with a frame and glaſſes during bad weather, by which aid they flower earlier, and often form many tubers at the joints.

CONUS, a Cone; a ſpecies of fruit, or ſcaly ſeed-veſſel, of the coniferous trees, as the pine-tree, &c. formed into a conical figure, and commonly called a Cone, *Conus*; but modern botaniſts have ſubſtituted in its place *Strobilas*. See STROBILUS.

This ſpecies of ſeed-veſſel is formed of an amentum, and compoſed of many hard woody ſcales, curiouſly arranged, and fixed by their baſe to an axis, which occupies the middle of the Cone, ſo they open only at top: in many ſpecies of pine-tree, the ſcales of the Cone are of a bony nature, and almoſt united, as thoſe of the cedar of Lebanon, Scotch pine, &c in fir, larch, arbor-vitæ, and cypreſs, the ſcales are of a ſubſtance like hard leather; and in juniper, ſavin, &c. they are united, and become fleſhy and ſucculent like a berry. Theſe ſcales, which compoſe the Cones, ſerve, at firſt, each as a calix to a fructification, and being perſiſtent, they harden by degrees to a bony or very hard ſubſtance, ſerving alſo as a ſort of pericarpium to the ſeeds, which are lodged naked principally betwixt the bottom of the ſcales, and by them nouriſhed as in a proper ſeed-veſſel.

The ſcales of the Cones often ſo cloſely involve the ſeeds, that they cannot be diſlodged without violence, by ſplitting the Cones open with an inſtrument driven through them, or till they are expoſed to the midſummer ſun, or before a fire, which cauſes them to open gradually. See PINUS.

The ſeeds themſelves are moſtly oblong, hard like a nut, and crowned with a large membranaceous wing.

Theſe ſeeds or kernels, in ſome ſpecies of *pinus*, are eatable, particularly thoſe of the *pinus pinea*, or ſtone-pine, being exceeding wholeſome, and good for coughs and conſumptions; and in Italy, where the trees abound, they are ſerved up to table with other fruits in the deſert, during the winter ſeaſon.

CONYZA, Fleabane.

It conſiſts of herbaceous and ſhrubby plants, adorned with compound flowers, and of which there is one ſmall ſhrubby ſpecies, pretty common in our green-houſes.

It is titled,

CONYZA *Candida.*

*Shrubby White-leaved Conyza.*] Conyza with a ſhort ſhrubby ſtalk, branching ſix or eight inches high; cloſely garniſhed with oval, ſmall, downy, white, ſilvery leaves; and from the ſides and ends of the branches, long woolly flower-ſtalks, each ſuſtaining two or three yellow compound flowers.

It requires ſhelter in winter, and is very beautiful in its low buſhy growth and ſilvery leaves: let it be kept in pots of rich earth, to be moved to a green houſe or garden-frame, to have ſhelter from froſt; and it may be propagated by ſlips of its branches in ſpring, which, if planted in pots, and plunged in

in a hot-bed about a month, and often watered, will grow freely; but cuttings planted in ſummer, often emit roots without the aid of a hot bed.

COREOPSIS, Tick-ſeeded Sunflower.

The plants are herbaceous very flowery perennials, proper for the pleaſure-ground, obtaining from three to ſix or eight feet ſtature, terminated by cluſters of compound radiated flowers.

Claſs and order, *Syngeneſia Polygamia Fruſtanea.*

*Characters.*] CALIX, compound radiated flower, having a double general cup; the outer one is of eight ſmall leaves, and the inner one is large and coloured. COROLLA, many hermaphrodite tubular florets form the diſc, and eight large flat neutral ones the ray. STAMINA, five ſhort filaments, and cylindric antheræ. PISTILLUM, a compreſſed germen, ſlender ſtyle, and bifid ſtigma; but no ſtyle nor ſtigma in the neutrals. PERICARPIUM, none. SEMINA, each hermaphrodite floret ſucceeds to an orbicular ſeed, bordered and horned at top.

The ſpecies of moſt note are the three following perennials.

[1]COREOPSIS *Alternifolia.*

*Alternate-leafed Virginia Coreopſis.*] Coreopſis with upright ſtrong ſtems ſeven or eight feet high, garniſhed on every ſide with ſpear-ſhaped, ſawed, alternate leaves, having decurrent winged foot ſtalks or borders, running from the baſe of one to the other, and the ſtems crowned by large, radiated, yellow flowers.

[2]COREOPSIS *Tripteris.*

*Ternate-leafed American Coreopſis.*] Coreopſis with upright, round, ſmooth ſtalks, ſix or ſeven feet high, garniſhed at each joint with trifoliate oppoſite leaves, and the ſtalks terminated by bunches of large flowers, having a yellow radius and purple diſc.

[3]COREOPSIS *Verticillata.*

*Verticillate Multifid-leafed Coreopſis.*] Coreopſis with upright, angular, ſtiff ſtalks, three or four feet high, branching by pairs, adorned round the joints with compound-winged, finely divided leaves; and from the ſides of the branches, long foot-ſtalks, each ſupporting one flower, having a dark-purple middle, and bright yellow ray.

Theſe have all perennial fibrous roots, and annual ſtalks, which riſe in ſpring, flower from July till October, and decay to the root in November.

The flowers are all compound, radiated, and pretty large, ſhaped like ſunflowers, but ſmaller, and are very ornamental.

All three ſpecies are good furniture for the large compartments of the pleaſure-ground, either for ſpacious borders, or the ſhrubbery plantations, introducing them in the vacant ſpaces between the ſhrubs, on the boundaries of lawns or principal walks, for all of them will exhibit a plentiful bloom from July or Auguſt, until prevented by froſt.

Their propagation is eaſily effected by ſlipping or dividing the roots in autumn, when the ſtalks decay, planting the ſlips at once where they are to remain, and they will call for no farther trouble than keeping them clean from weeds, and to cut down the decayed ſtalks annually in autumn.

CORIANDRUM, Coriander.

It conſiſts of herbaceous annual herbs of the culinary and medical tribe, and their leaves are the uſeful parts for the kitchen, and the ſeeds for medicine.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbellate flowers, having a general involucrum, ſcarce monophyllous, and the partial one of three leaves, and a ſmall five-parted calix to each floret. COROLLA, a difform, radiated, general umbel, and the florets compoſed of five heart-ſhaped inflexed petals. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, a germen under each floret, two ſtyles, and radiated ſtigmas. PERICARPIUM, none; a ſpherical two-parted fruit, and two hemiſpherical ſeeds.

There are but two ſpecies, both of which have divided ſmall leaves, ſomewhat reſembling parſley; but there is but one ſpecies generally cultivated.

The ſpecies are,

[1]CORIANDRUM *Sativum.*

*Cultivated Coriander.*] Coriandrum with a ſmall, fibrey, white root, crowned by many-parted leaves, having broadiſh ſegments; and in the centre an upright, round, branchy ſtalk, two feet high, having all the branches terminated by umbels of flowers, ſucceeded by globular fruit.

[2]CORIANDRUM *Teſticulatum.*

*Teſticulated Smaller Coriander.*] Coriandrum with ſmaller many-parted leaves, and upright, angular, ſlender, branchy ſtalks, terminated by umbels of flowers, ſucceeded by teſticulated or twin fruit.

The firſt ſpecies is that commonly cultivated,

vated, which, as a garden-herb, is ſometimes uſed both for culinary uſes in ſoups, &c. and as an ingredient in ſallads; but as the leaves are of a fœtid ſmell, it is in no great eſteem in England, except in ſome foreign families.

It is propagated by ſeed, which for garden uſe may be ſowed any time in ſpring or ſummer, ſowing it in ſhallow drills half an inch deep, and let the drills be ſix inches aſunder, obſerving, as the plants ſoon fly up to ſeed, a repetition of five or ſix ſowings is requiſite from March till September; and the laſt ſowing ſhould be on a warm border, to ſtand the winter.

When this plant is to be cultivated for its ſeed, it ſhould be ſowed in March, either in drills a foot aſunder, or by broad-caſt, and rake it in; and when the plants are an inch or two high, hoe them to ſix or eight inches diſtance.

CORIARIA, the Tanner's, or Myrtle-leafed Sumach.

It is a hardy deciduous, ſmall-leafed, flowering ſhrub for the ſhrubbery, adorned with ſpikes of quinquepetalous flowers.

Claſs and order, *Dioecia Decandria.*

*Characters.*] CALIX, male and female flowers on diſtinct plants, having ſmall five-leafed cups. COROLLA, five oval petals. STAMINA, ten filaments, and oblong antheræ. PISTILLUM, five germina, five ſtyles, and ſimple ſtigmas. PERICARPIUM, none; the petals become a fleſhy angular berry, incloſing five ſeeds.

The ſpecies is,

CORIARIA *Myrtifolia.*

*Myrtle-leafed Coriaria.*] Coriaria with a ſhrubby, pithy, brown ſtem, cloſely branching from the bottom, and forms a buſhy head three or four feet, thickly garniſhed with oblong, pointed, ſmalliſh, bright-green leaves, in pairs oppoſite; and at the ſides and ends of the branches, ſmall ſpikes of whitiſh flowers.

*Varieties.*] Male-flowered Coriaria—Female Coriaria.

This is a proper ſhrub for any of the common ſhrubbery compartments, to encreaſe the variety, where its roots will creep conſiderably, and ſend up ſpawn, or many ſmall ſuckers, for encreaſe.

It is eaſily propagated by ſuckers from the root, which it affords plentifully, and may be taken off with fibres every autumn or winter.

Layers in autumn will alſo be rooted in a year.

CORNUS, Cornel-tree, or Cornelian-Cherry, and Dog-wood.

This genera conſiſts principally of hardy deciduous trees and ſhrubs, proper for the ſhrubbery plantations, adorned with oblong leaves, and umbellate white flowers.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX, umbellate flowers, included in a four-leaved coloured involucrum, the florets having a very ſmall four parted cup. COROLLA, each floret compoſed of four oblong acute petals. STAMINA, four erect filaments, and roundiſh incumbent antheræ. PISTILLUM, a roundiſh germen under the receptacle, filiforme ſtyle, and blunt ſtigma. PERICARPIUM, a roundiſh berry, including a bilocular nut, having two kernels.

There are three ſpecies of the tree and ſhrub kind, furniſhing ſeveral eminent varieties, one of which ſpecies grows wild in England; the reſt are of American growth, but all hardy enough to ſucceed here in the full ground.

The ſpecies are,

[1]CORNUS *Mas.*

*Male Cornus, or Cornelian Cherry-tree.*] Cornus with an upright tree-ſtem, riſing twenty feet high, branching, and form a large head, garniſhed with oblong leaves, and ſmall umbels of yelloviſh-green flowers at the ſides and ends of the branches, appearing early in ſpring, ſucceeded by ſmall, red, cherry-like, eatable, acid fruit.

This ſpecies is eſteemed both as a flowering ſhrub, and for its fruit, to preſerve for making tarts.

The wood of this tree being extremely hard, derives the name *Cornus*, i. e. of a horn-like hardneſs and duration, and is ſaid to laſt as long as iron.

[2]CORNUS *Sanguinea.*

*Bloody-twig, or Common Dog-wood.*] Cornus with an upright tree-ſtem, branching ten or twelve feet high, having blood-red ſhoots, garniſhed with oblong, pointed, nervous leaves, two inches long; and all the branches terminated by umbellate white flowers, ſucceeded by black berries.

*Variety.*] With variegated leaves.

This ſpecies grows wild in the hedges in many parts of this kingdom, but is cultivated in the nurſeries, and may, with propriety, be introduced in large ſhrubberies, both for the variety of its foliage and flowers, as well as for the ſingular appearance of its red ſhoots in winter, when devoid of leaves.

[3]CORNUS *Florida.*

*Virginia*

*Virginia Dog-wood.*] Cornus with a tree ſtem, branching twelve or fifteen feet high, and fine red ſhoots, garniſhed with large obverſe heart-ſhaped leaves; and the branches terminated by umbellate white flowers, having a large involucrum, ſucceeded by dark red berries.

*Variety.*] Virginia Dogwood with a red involucrum.

The following are ſuppoſed to be only varieties of the above ſpecies.

*Female Narrow leaved Virginia Dog-wood.*] Cornus with an upright tree-ſtem, branching eight or ten feet high, having very red ſhoots; ſpear-ſhaped, acute, nervous leaves; and the branches terminated by umbellate white flowers, ſucceeded by red berries.

*Blue-berried American Dog-wood.*] Cornus with an upright ſtem, branching eight or nine feet high, having beautiful red ſhoots; large oval leaves, hoary and whitiſh underneath; and all the branches terminated by umbels of white flowers, ſucceeded by bunches of large, oval, blue berries.

This variety is remarkably ornamental both in its fine, large, whitiſh foliage and flowers in ſummer, and its numerous bunches of elegant blue berries in autumn.

*White-berried Penſylvanian Dog-wood.*] Cornus with an upright ſtem, branching eight or ten feet high, and very red ſhoots; oblong-oval leaves, whitiſh underneath; and large umbels of white flowers, ſucceeded by white berries.

*White-leaved American Dog-weed.*] Cornus with an upright ſtem, branching eight or nine feet high; ſpear-ſhaped, acute, ſmooth leaves; and large umbels of white flowers, and red berries.

Moſt of theſe ſpecies are ſtrong ſhooters, well clad with leaves, from two to four inches long, of a lightiſh colour.

All theſe trees are elegant furniture for large ſhrubberies, wilderneſs-works, and all other ornamental plantations, where they will effect a fine variety with their leaves and numerous flowery umbels in ſummer, their cluſters of berries in autumn, and thoſe of the Dog-wood kinds, with their beautiful red ſhoots in winter, when the leaves are fallen.

They all proſper in any common ſoil and expoſure; and as to their culture, permit them to aſſume their own natural growth, except juſt retrenching any rambling ſhoots, and clear away ſuckers from the roots, and all dead wood from the branches.

*Propagation of all the Sorts.*

Their propagation is by ſeed, layers, and cuttings, all in the full ground.

By ſeeds.—The ſeed of the American kinds generally arrive from thence in ſpring, which ſhould be ſown as ſoon as poſſible in a bed of good earth half an inch deep; but they rarely germinate till ſpring following, unleſs they are ſowed in autumn; therefore the ſeeds of the Cornelian-cherry, and Common Dog wood, as alſo thoſe of all the others that ripen here, ſhould be ſown in October, and they will, for the general part, grow the ſucceeding ſpring; and when the plants are a year old, plant them out in nurſery-rows, and when from two to four or five feet high, are of due ſize for the ſhrubbery, &c.

By layers.—Let the ſhoots of the year be layed in autumn, they will all be well rooted, and fit to tranſplant the autumn following.

By cuttings.—This may be performed in October or November, chuſing ſtrong ſhoots of the year, cut ten or twelve inches long; plant them three parts in the ground, and they will be well rooted by autumn following.

Suckers from the roots will alſo make good plants.

When theſe ſhrubs are from two to four or five feet high, they are fit for the ſhrubbery.

CORONILLA, Jointed-podded Colutea, and *Emerus*, or Scorpion-Sena.

Of this genus there are ſome ſhrubby evergreens and deciduous ſhrubs, proper for the green-houſe and ſhrubbery collections, ornamented principally with pinnated many-lobed leaves, and cluſters of papilionaceous yellow flowers, ſucceeded by long jointed ſeed-pods.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, compreſſed, erect, and bifid. COROLLA is papilionaceous; the vexillum heart-ſhaped, and the ſides reflexed; the wings oval, and join at top; and the carina ſhort, compreſſed, and pointed. STAMINA, ten filaments, nine of them united, the other ſtands ſeparate, and ſmall antheræ. PISTILLUM, an oblong taper germen, briſtly ſtyle, and obtuſe ſtigma. PERICARPIUM, a long, taper, jointed pod, having many ſeeds.

The ſpecies are as follow: the firſt four are low, rather tender ſhrubs, and are commonly retained in pots for ſhelter of a green-houſe in winter.

[1]CORONILLA *Glauca.*

*Sea green-leaved Coronilla.*] Coronilla with a ſhrubby ſtalk, branching two feet high; pinnated evergreen leaves, of about five pair of glaucous-coloured lobes, terminated by an odd one; and, from the ſides of the branches, many roundiſh bunches of bright yellow odoriferous flowers.

[2]CORONILLA *Argentea.*

*Silvery-leaved Cretan Coronilla*] Coronilla with a ſhrubby ſtalk, branching two feet high; pinnated leaves of nine or eleven ſilvery lobes; and roundiſh bunches of yellow flowers.

[3]CORONILLA *Valentina.*

*Valentian Nine-lobed Coronilla.*] Coronilla with a ſhrubby ſtalk, branching a foot or eighteen inches high; pinnated leaves of about nine pair of ſmall lobes; and the branches terminated by bunches of yellow flowers.

[4]CORONILLA *Juncea.*

*Ruſh-lobed Spaniſh Coronilla.*] Coronilla with a ſhrubby ſtalk, branching two feet high, garniſhed with leaves of five and three very narrow, ſpear-ſhaped, fleſhy lobes, and ſmall bunches of bright yellow flowers.

The following is a hardy, large, very beautiful, deciduous, flowering ſhrub, and remarkably floriferous.

[5]CORONILLA *Emerus.*

*Emerus, or Scorpion-Sena.*] Coronilla with a ſhrubby ſtem, branching numerouſly ſix or eight feet high, cloſely garniſhed with winged leaves of three pair of lobes, terminated by an odd one; and at the ſides of the branches, numerous long flower-ſtalks, each ſupporting two or three large yellow flowers, ſucceeded by longiſh pods.

*Variety.*] Dwarf Scorpion-Sena.

The flowers of all theſe ſhrubs are of the papilionaceous or butterfly kind, being compoſed of a ſtandard, two wings, and a *carina*, or keel, ſee the *Characters*, appearing commonly in May and June in great plenty; and the *Emerus*, or Scorpion-Sena, appears covered with them, continuing long in beauty; and all the ſorts are ſucceeded by jointed pods in autumn, filled with ripe ſeed.

The firſt four ſpecies are rather tender, and, although they will live in open air in mild winters, they are impatient of ſevere weather; they ſhould therefore, for the general part, be potted, to be moved to ſhelter of a green-houſe or glaſs-frame in winter; and others may be placed in a ſheltered ſituation in the full ground, to take their chance.

The fifth ſort, *Scorpion-Sena*, and variety, are hardy and elegant flowering ſhrubs for the principal ſhrubbery compartments in gardens of any extent, and there are but few hardy ſhrubs that make a finer appearance.

*Propagation of all the Sorts.*

The firſt four ſpecies are propagated by ſeeds in ſpring, either on a warm border, or in a ſlender hot bed; but the latter will forward them greatly, ſowing the ſeeds in pots of rich earth half an inch deep, and plunge them in the hot-bed; and when the plants are two or three inches high, prick them in ſeparate ſmall pots, allowing ſhade, water, and air, and harden them gradually to the full air in June, in which let them remain till October, then moved to ſhelter of a frame during winter, but cover them only in time of froſt.

The *Scorpion-Sena* may be encreaſed plentifully both by ſeeds, and by layers and cutings.

Sow the ſeeds in March, in a bed of light earth, and cover them half an inch deep, giving occaſional waterings in dry weather, and the plants will riſe in a month or ſix weeks; and when they have had a year or two's growth, tranſplant them from the ſeed-bed in nurſery rows, and in two or three years after they will be large enough for the ſhrubbery.

By layers. It may be done in autumn or winter, chuſing the one-year's ſhoots, giving them a gentle twiſt, and they will be rooted by the winter following.

By cuttings. Plant ſome of the young ſhoots in October or November in a ſhady border, giving water the following ſpring and ſummer, and many of them will be rooted by autumn.

COROLLA, Corolla, or Little Crown, the botanic name for the flower-leaves, i. e. the beautiful coloured leaves of the flower, which immediately ſurround and defend the organs of generation, and ſtand within the calix, where there is any.

This conſpicuous and beautiful part of plants, the Corolla, is deſigned not only as an ornament to the reſpective plants, but alſo to defend and nouriſh the tender generative organs, till they have performed their fecundating function, &c. and is therefore by Linnæus, in aſſimilating the animal and vegetable kingdoms, diſtinguiſhed by the name of *auleum floris*, or the palace in which the nuptials of the plant is celebrated.

The

The Corolla may be ſaid to conſiſt of two parts, the petals, and the nectarium; the laſt of which, however, is rather a ſtriking ſuperfluity, or occaſional appendage in ſome, than a neceſſary part of every flower, ſee NECTARIUM; ſo that the petals are always to be conſidered as the principal part of the Corolla.

A Corolla of one petal is termed *monopetalous*; of two, *dipetalous*; of three, *tripetalous*; of four, *tetrapetalous*; of five, *pentapetalous*, or *quinquepetalous*; of ſix, *hexapetalous*, or *ſexpetalous*; of eight, *octapetalous*; or of many *polypetalous*; though all flowers, having more than one petal, are ſpecies of *polypetalous*.

Obſerve, in reſpect to number, that, in the characteriſtic deſcription of the Corolla, the number of petals are always to be determined from their ſingle or common ſtate, never from the doubles, which are only accidental varieties; as, for example, the *cheiranthus*, or wallflower and ſtock-gilliflowers, in their common ſtate, the Corolla conſiſts only of four petals, but in the doubles they are innumerable; and ſo of all other flowers that are apt to run into doubles, which are properly enough ſtyled luxuriant flowers. See LUXURIANS *Flos*, and PLENUS *Flos*.

The real numbers of petals in the Corolla is determined from the baſe; that is, when the Corolla appears of two, three, or many parts or diviſions, continued to, or very near the bottom, it is conſidered as ſo many diſtinct petals, notwithſtanding the baſe of the ſeveral petals may connect, as is the caſe of the mallow tribe, the genus *Narciſſus*, and many others; but when the limb, or upper ſpreading part of the Corolla, is divided only about half way, or a little more or leſs, into ſeveral parts, it is conſidered only as one petal, *monopetalous*, divided into ſo many ſegments or parts.

Segments or diviſions are very frequent in monopetalous flowers, which very commonly have their limb divided into five parts; in polypetalous flowers theſe diviſions of the real petals ſeldom prevail.

In reſpect to the figure of the Corolla and petals, that, in monopetalous flowers, there being but one petal, it is either bell-ſhaped, funnel-ſhaped, ſalver-ſhaped, wheel-ſhaped, ringent or maſque-ſhaped, as explained below; and in a polypetalous flower, the Corolla is either regular, by having all its petals of equal figure, magnitude, proportion, and poſition, as in tulip, Narciſſus, lily, &c. or irregular, by the petals aſſuming different figures, ſizes, and poſition, in the ſame Corolla, as in *aconitum*, or monk's hood, balſamine, columbine, and lark-ſpur, &c.

In a monopetalous Corolla, the lower hollow part is called the tube, the upper ſpreading part the limb, the opening of the tube the chaps or jaws, *faux*. See TUBUS, LIMBUS, and FAUX.

In a polypetalous Corolla, the lower part is termed the claw, *unguis*; the upper ſpreading part *lamina*. See UNGUIS and LAMINA.

The Corolla has different terms, according to the figure it aſſumes, as follow.

*Corolla Companulata*, a bell-ſhaped Corolla, conſiſts of one petal, regular and hollow like a bell, as in the genus campanula, convolvulus, and deadly night-ſhade.

*Corolla Infundibuliformis*, a funnel-ſhaped Corolla, conſiſts of one regular petal, with a conic ſhaped limb, ſtanding upon a long tube, as in *datura*, or thorn-apple, oleander, tobacco, and marvel of Peru.

*Corolla Hypocrateriformis*, a ſalver-ſhaped Corolla, has one regular petal, having a plane or flat-ſpreading limb ſtanding on a very ſhort tube, as in periwinkle, &c.

*Corolla Rotata*, a wheel-ſhaped Corolla, has one regular petal, having a plane or flat limb without any tube, ſometimes entire, and ſometimes divided, as in *borago*.

*Corolla Ringens*, a gaping or grinning Corolla, has one irregular petal, ſhaped ſometimes like a maſque or ſnout of an animal with two lips, as in ſnap-dragon, or calve's-ſnout; ſometimes is terminated behind by a nectarium, in form of a tube, or ſpur of a fowl, as obtains in *antirrhinum linaria*, or toad-flax. See RINGENTUS and PERSONATUS.

*Corolla Labiatus*, a labiated or lip Corolla, having two lips, and is a ſpecies of *Corolla Ringens*. See LABIATUS and VERTICILLATA.

*Corolla Cruciformis*, a cruciforme, or croſs-ſhaped Corolla, compoſed of four equal petals, that ſpread at top on their claws in form of a croſs, exemplified in ſtock-gilliflower, ladies-ſmock, and the other numerous flowers of the claſs *tetradynamia*.

*Corolla Papilionacea*, a papilionaceous or butterfly ſhaped Corolla, compoſed of four or five irregular petals, which, from their figure and poſition, bear an obvious reſemblance to a butterfly with its wings expanded, exemplified in the pea, bean, kidney-bean, and

and laburnum, &c. the petals are characterized by diſtinct names; the upper one is called the ſtandard, *vexillum*; the two ſide ones the wings, *alæ*; and the lowermoſt one, ſometimes concave and divided, is called the keel, *carina*, from its reſemblance to the bottom or keel of a boat; is ſometimes of one petal, and ſometimes two united. See PAPILIONACEA.

Moſt of the plants in the claſs *diadelphia* have papilionaceous flowers.

*Corolla Regularis Polypetala*, a regular polypetalous Corolla, having two, three, or many regular petals, of equal ſhape, magnitude, and poſition, as in roſe-campion, holly-hock, tulip, lily, &c.

*Corolla Irregularis Polypetala*, an irregular polypetalous Corolla, conſiſts of ſeveral irregular diſſimilar petals, generally accompanied with a nectarium, as in *aconitum*, balſamine, lark-ſpur, *orchis*, or bee-flower, *cypripedium*, or lady's-ſlipper; and moſt of the papilionaceous flowers come alſo under this denomination. See IRREGULARIS *Flos*.

With reſpect to duration of the Corolla, the petals ſometimes fall off immediately after their expanſion, or endure but a few hours, or ſometimes but one day; ſometimes they are of ſeveral days, or even weeks, duration, and ſometimes the Corolla withers on the plant without dropping at all, as often obtains in the cucumber, in which the flower ſometimes remains, on the end of the fruit, till fit to gather; but in moſt plants the Corolla falls off with the ſtamina and other parts ſoon after the fecundating function is effected; to aſſiſt which, by defending the generative organs, is apparently the main deſign of the Corolla.

CORTUSA, Bear's-ear Sanicle.

It furniſhes two very low, herbaceous, flowery perennials, crowned by umbels of monopetalous, wheel-ſhaped, auricula-like flowers, having five ſtamina and one ſtyle.

The ſpecies are,

[1]CORTUSA *Matthiolus*.

*Bear's-ear Sanicle of Matthiolus*.] Cortuſa with a fibrey root, crowned by many oblong, heart-ſhaped, indented leaves, in a cluſter, and among them round flower-ſtalks ſix inches high, terminated by umbels of fine red flowers longer than the calix.

[2]CORTUSA *Gmelini*.

*Bear's-ear Sanicle of Gmelin*.] Cortuſa with a fibrey root, crowned by a tuft of heart-ſhaped leaves, and flower-ſtalks four inches high, terminated by umbels of pale red flowers ſhorter than the calix.

They are natives of mountainous rocky parts abroad, ſo muſt have a dry lean ſoil; or may be kept in pots of dry ſandy earth, placed in the ſhade, and in ſummer muſt be duly watered; and their propagation here is by ſlipping the roots in October.

CORYLUS, the Hazel or Nut-tree, Filbert, &c.

This genus furniſhes two ſpecies only, both of them of the large ſhrub kind, hardy and deciduous, and of which there are ſeveral varieties, valuable in gardens for their fruit, as alſo by way of variety in large ſhrubbery and wilderneſs works.

Claſs and order, *Monoecia Polyandria*.

*Characters*.] CALIX, male and female flowers, remote on the ſame plant; MALES are collected in a long katkin, or ſcaly amentum, each ſcale forming a calix. COROLLA none. STAMINA, many very ſhort filaments in each ſcale, and oblong erect antheræ; FEMALE FLOWERS are included in the future bud ſitting cloſe to the branches, having a thick two-leaved leathery calix, enlarging to the length of the fruit, and lacerated at the margin. PISTILLUM, a roundiſh germen, two ſtyles, and ſimple ſtigma. PERICARPIUM, none; the germen becomes an oval nut, pointed at the top.

Botaniſts admit of but two real ſpecies of *Corylus*, and that the Hazel, Filbert, Cob-nut, &c. are all varieties of the ſame ſpecies, and that the common Hazel or Nut-tree of the woods is the original ſpecies.

The ſpecies are,

[1]CORYLUS *Avellana*.

*Avellana, or Common Hazel or Nut-tree*.] Corylus with an upright tree-ſtem, very branchy, and forms a full head from ten to twenty feet high, garniſhed with large roundiſh, pointed leaves, having oval ſtipulæ, and male flowers, growing in long yellowiſh katkins, and female flowers cloſe to the branches, appearing in ſpring, of a red colour, ſucceeded by the fruit in large cups, ripening in autumn.

*Varieties*.] Common Wood-nut with a white-ſkinned kernel—Red Wood nut, having a red-ſkinned kernel.

*Large Cluſter Wood-nut*—The Nuts grow in large cluſters, and the Nuts are alſo large and fine, and very proper for garden culture.

*Great Cob-nut*—A remarkably large round Nut with a thick and very hard ſhell, more valuable

valuable for its ſize for variety, than any particular excellency in its kernel.

*Long-nut*—is an inch and half, or two inches long, broadiſh and rounded at the top, but does not kernel well.

*Barcelona, or Spaniſh-nut*—A large, roundiſh, thin-ſhelled Nut, always remarkably well-kernelled, which is exceeding ſweet and good, and will ripen in England, ſo is a very proper ſort for culture, and the tree is a ſtrong ſhooter.

*Filbert-Nut-tree*—The branches grow more erect, and the *ſtipulæ* more oblong than the other kinds. and the fruit is oblong, large, thin-ſhelled, and well filled with exceeding ſweet kernels, and the Nuts frequently grow in cluſters; of this there are two notable varieties—White-ſkinned Filbert—Red-ſkinned Filbert—The Red ſort is in moſt eſteem, being coveted for the beauty of its red kernel. The trees of theſe two varieties are very diſtinguiſhable; thoſe of the White ſort have the ſhoots and leaves of a light green colour, which of the Red kind are of a dark or reddiſh-green. Both the varieties are good bearers, and will ſucceed almoſt any where; they are therefore well worth culture in every garden or orchard.

[2]CORYLUS *Colurna.*

*Colurna, or Dwarf Byzantine Nut-tree.*] Corylus with an upright ſhrubby ſtem, branching four or five feet high; roundiſh, pointed leaves, and narrow acute ſtipulæ; and large round Nuts growing in cluſters.

The flowers of all theſe trees are male and female, at a diſtance on the ſame tree; the males appear in long ſcaly amentums, formed in autumn and winter, and the females, or fruitful flowers, come out in ſpring, in cluſters cloſe to the branches, having thick, two-leaved, torn cups, appearing of a reddiſh colour, and the calix incloſes the fruit, and accompanies it to maturity, generally one Nut in each cup.

All the ſorts of *Corylus* are very hardy, and will proſper in almoſt any ſituation and ſoil, high or low, or on the ſides of hills, as is evident from the common Hazel growing wild in ſuch abundance in woods, wilds, foreſts, and field hedges, in every county of the kingdom, and from which the Nuts are collected that ſupply the different markets; the trees alſo turn out to good account when growing in coppices, to cut as underwood, and for poles for various uſes, as hoops, ſpars, hurdles, handles to huſbandry implements, walking-ſticks, fiſhing-rods, and many other uſes, and for which purpoſes they will afford a falling every fifth, ſeventh, or eighth year, according to the uſes for which they are deſigned.

For purpoſes in gardening, ſeveral of the varieties are worthy of culture, for the ſake their fruit; particularly the Cluſter-nut, Large Cob-nut, Barcelona-nut, and the two varieties of Filberts; all of which may either be trained as high ſtandards, half ſtandards, or dwarfs. When required for ſtandards, they ſhould be planted at fifteen feet diſtance, either in the garden, or on the edge of orchards, &c. or they may be dropped ſingly in different parts, to form the greater variety; and in pleaſure-grounds, ſome may be diſpoſed by the ſides of ſhady walks, or other parts of the wilderneſs or ſhrubbery works contiguous to the walks, ſome as dwarfs, others as half and full-ſtandards, where they will exhibit variety as common ſhrubs, and the progreſs of the fruit will afford entertainment in excurſions through the plantation, as well as furniſh a ſupply for the deſert.

Obſerve, when you deſign them to form full ſtandards, you ſhould train them with a ſingle ſtem five or ſix feet high, at which height ſuffer them to branch out and form a head, according to their natural growth; but for half ſtandards, a three or four feet ſtem is ſufficient; and for dwarfs, train them with a ſingle ſtem to a foot and half in height, then top them, and they will branch out, and form a low ſpreading head.

All the culture theſe trees require, after being planted out where they are to remain, is to clear the bottom annually from ſuckers ariſing from the root, and the ſtem from all ſide-ſhoots; and as to their heads, let them, for the general part, take their natural growth, except juſt retrenching any very rambling ſhoot or branch.

But ſometimes theſe trees are planted to form a kind of hedge, ſetting them five feet diſtance; ſo leave them entirely to nature to ſhoot from the bottom, ſides, and top, in their own way; but theſe never produce ſo large, nor fine-flavoured fruit, as trees with one ſtem, and ſtand at ſuch diſtances, that their heads have full ſcope to ſpread regularly every way.

When a full plantation of theſe trees are deſigned for their fruit, I ſhould adviſe planting them in rows not leſs than fifteen or twenty feet diſtance, nor leſs than ten or fifteen feet aſunder in the lines.

When deſigned to plant a coppice of common Nut-trees, for poles, &c. they ſhould be previouſly raiſed from the Nut in the nurſery way; and, when two or three feet high, plant them out where they are to remain, in rows five feet diſtance, and a yard in the rows, and they will be fit for the firſt fall in eight, ten, or twelve years, according to the uſes they are deſigned for, and every fifth, ſixth, or ſeventh year afterwards.

*Propagation of all the Varieties.*

All the ſorts of *Corylus* may be propagated with facility by planting the Nuts, by layers, ſuckers from the root, and by grafting and budding.

By planting the Nuts: this ſhould be done in ſpring, but until the arrival of that ſeaſon it is proper to preſerve the Nuts in ſand, in an airy room or ſhed, and in February plant them in drills near two inches deep, and the plants will appear in ſix or eight weeks, which, when a year old, plant out in nurſery-rows, and there train them two or three years, for the purpoſes wanted, i. e. either as ſtandards, half ſtandards, or dwarfs; then tranſplant them into the garden. It is to be obſerved, that in raiſing theſe trees from the Nut, the ſorts are not to be always depended on; for, like other ſeedling trees, they often vary, ſo that the moſt certain method to continue the reſpective ſorts is by layers, &c. obſerving, however, that in raiſing from Nuts, ſometimes trees are obtained, which produce Nuts as good, and ſometimes better than thoſe from which they were raiſed.

By layers: this is one of the moſt certain methods of continuing the reſpective varieties diſtinct, for layers of the Cluſter-nut never fail to produce fruit exactly of the ſame kind and manner; the ſame of the Cobs, Barcelona, and Filberts; and this is a very eaſy and expeditious method of propagation, for every twig layed will readily grow; therefore, in autumn or winter, having recourſe to ſome low-growing trees, let ſome of the lower branches, that are well furniſhed with young ſhoots, be pegged down in the ground, then lay all the young ſhoots thereof in the earth with their tops out, every one of which will root and advance in length, and be fit to tranſplant by autumn following, when they ſhould be ſeparated and planted in nurſery-rows two feet aſunder, and trained as obſerved of the ſeedlings: but when any conſiderable quantity are to be raiſed this way, it is eligible to form ſtools for that purpoſe, by previouſly a year before heading down ſome trees near the ground, to throw out a quantity of ſhoots near the earth convenient for laying, and they will furniſh a ſupply for that uſe annually.

Suckers, ariſing from the roots of trees raiſed by either of the above methods, if taken up in autumn, winter, or ſpring, with good fibres, will alſo grow, form proper plants, and produce the ſame ſort of fruit as their parent plant; and ſuckers of theſe may alſo be uſed for the ſame purpoſe.

By grafting and budding: theſe methods have alſo the ſame effect as layers, of continuing any particular variety with certainty, and the operation is to be performed in the uſual way on ſtocks of any of the varieties of this genus. See GRAFTING, &c.

CORYMBUS, a mode of cluſter-flowering, reſembling the form of a cluſter of ivy-berries, and differs from the umbel and racemus, and other modes of cluſter-flowering. See UMBELLA and RACEMUS.

A Corymbus-cluſter is diſtinguiſhable, in that many partial flower-ſtalks ariſe from different parts of the common ſtalk; and although of unequal lengths, by coming out higher or lower on the main ſtalk, yet they all riſe to the ſame height, ſo as that the flowers they ſupport forms a flat and even ſurface at top, exemplified in *ſpiræa opulifolia*, *tanacetum*, &c. and differs from an umbel, in which all the partial flower-ſtalks proceed from one point or common centre, and riſe alſo to an equal height. See UMBELLA.

A Corymbus is either ſimple or compound; ſimple, when the partial flower-ſtalks have no branches; compound, when they branch out into ſeveral ramifications, yet ſo as to form an even ſurface at top.

COTYLEDON, Navel-wort, *Cotyledon*.

The plants are ſucculent perennials, both of hardy nature, and for the green-houſe and ſtove, from half a foot to a yard and half high, adorned with roundiſh and oblong, thick, fleſhy leaves, and monopetalous, bell-ſhaped, yelloviſh flowers, in ſpikes and umbels.

Claſs and order, *Decandria Pentagynia*.

*Characters.*] CALIX monophyllous and five-parted at top. COROLLA is monopetalous, bell-ſhaped, and five parted, at the brim. STAMINA, ten erect filaments, and four-furrowed antheræ. PISTILLUM, five germina, and ſtyles, and ſimple ſtigmas. PE-

RICARPIUM, five oblong, ventricoſe, univalvular capſules, having many ſmall ſeeds.

The ſpecies are,

[1]COTYLEDON *Umbilicus.*

*Umbilicated Cotyledon, or Common Navel-wort.*] Cotyledon with round, target ſhaped, hooded, ſerrata-indented, fleſhy leaves, directly from the root, on foot-ſtalks joined to the middle, and the upper ſurface umbilicated like a navel; and amidſt them branching leafy flower-ſtalks, from half a foot to a yard high, terminated by long ſpikes of erect cloſe-ſitting flowers, of different colours in the varieties.

*Varieties are*] Umbilicated Cotyledon with yellow flowers—with reddiſh flowers—with whitiſh flowers—with ſtreaked flowers—with creeping roots—with tuberous roots.

This ſpecies and varieties grows wild in England upon old walls, buildings, and rocky places; and in gardens may ornament artificial ruins, rock-work, and grottos.

They derive the name Navel-wort from the form of its umbilicated leaves.

The three following are ſhrubby green-houſe exotics from Africa.

[2]COTYLEDON *Orbiculata.*

*Orbiculate-leaved Cotyledon.*] Cotyledon with thick, ſucculent, ligneous, perennial ſtalks, emitting crooked irregular branches, and grows from one foot to a yard or more high, ornamented with roundiſh, plane, fleſhy, entire leaves, having purpliſh edges; and at the ends of the branches, umbellate cluſters of pale yellow flowers.

[3]COTYLEDON *Hemiſpherica.*

*Hemiſpherical-leaved Cotyledon.*] Cotyledon with a thick, ſucculent, perennial ſtalk, very branchy, and but ſix or eight inches high, garniſhed with ſemi-globular thick leaves, one ſide being convex, the other plane, having purpliſh edges; and at the top of the branches, ſeveral greeniſh-purple-tipped flowers.

*Variety.*] With ſpotted leaves.

[4]COTYLEDON *Spuria.*

*Long Spatulate-leafed Cotyledon.*] Cotyledon with thick, ſucculent, ligneous, perennial ſtalks, branchy, and from one to two or three feet high; long, narrow, ſpatulate-ſhaped, fleſhy, alternate leaves; and yellow flowers, on long fleſhy foot-ſtalks at the ends of the branches.

The following is a ſtove plant from India and Ægypt.

[5]COTYLEDON *Lacinata.*

*Cut-leaved Cotyledon.*] Cotyledon with an upright, jointed, ſucculent, perennial ſtalk, a foot high; broad, trifid, thick, ſucculent, greyiſh, oppoſite leaves; and from the ends of the branches, golden-yellow quadrifid flowers.

The laſt four ſpecies are perennial in ſtalk and branches, are very ſucculent, and become ligneous or ſhrubby; the leaves are alſo ſucculent, commonly of a greyiſh colour, and remain the year round. The flowers are univerſally monopetalous, bell, or funnel-ſhaped, which in the laſt four ſorts are produced on long, thick, fleſhy foot ſtalks, appearing at different times of the year; and only the firſt ſort produce ſeeds in England.

For purpoſes in gardening, the *Cotyledon Umbilicus* may be introduced to adorn rock-work, ruins, &c. or will ſucceed in any dry gravelly ſoil; and the ſecond, third, and fourth ſorts, exhibiting a curious ſingularity in their general habit, merit a place in the green-houſe collection; as likewiſe the fifth ſort for the ſtove; obſerving, that theſe laſt four ſorts, being very ſucculent, muſt always be retained in pots of dry ſandy or rubbiſhy compoſt, and managed as other ſucculents of the green-houſe and ſtove departments. See SUCCULENT PLANTS, &c.

*Propagation.*

The firſt ſort may be raiſed from ſeed in any dry gravelly ſoil, or ſcattered in the crevices of rock-work, grottos, or old buildings, and covered with earth; the plants will come up, and afterwards propagate themſelves.

All the other ſorts are eaſily propagated by cuttings of their ſucculent branches any time from May till Auguſt; the cuttings may be from three to five or ſix inches long, which, previous to their planting, ought to lie a week or ten days, to dry over the cut part; then plant them in pots of dry compoſt, as prepared for other ſucculents, ſee COMPOST; and then, as to the green-houſe ſorts, place them either in the green-houſe, or a frame, to have ſhelter from wet, and occaſional ſhade, though it would be of particular advantage to plunge all the ſorts in a bark bed, giving occaſional ſhade, and water once a week, and they will be rooted in a month or ſix weeks, when thoſe of the green-houſe ſhould be hardened to the full air for the remainder of the ſummer.

COTYLEDONES, Cotyledons, the ſide-lobes or covers of the ſeed, which be-

comes alſo the two firſt leaves of the plant; called alſo Cotyledons, or the ſeminal or ſeed-leaves; are generally ſmooth and fleſhy, and moſt commonly two in number, as in cucumber, and moſt other plants, and are very different from the proper leaves that are afterwards produced.

The lobes accompany the plant for ſome time after its eruption from the earth, till having acquired ſufficient ſtrength and growth, the ſeminal leaves become uſeleſs, wrinkle, wither, and die away.

CRAMBE, Sea Cabbage, or Sea-beach Kale, or Sea Colewort.

The plants are herbaceous eſculents, conſiſting of perennial roots, producing annually large cabbage-like leaves, ſpreading on the ground, and robuſt flower-ſtalks; and the young ſhoots of the plant, juſt iſſuing from the earth, are excellent eating.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, four oval, patent, deciduous leaves. COROLLA, four large, broad, ſpreading, cruciforme petals. STAMINA, four long and two ſhort filaments, two-parted at top, and ſingle antheræ. PISTILLUM, an oblong germen, no ſtyle, but a thick ſtigma. PERICARPIUM, a roundiſh berry, containing one ſeed.

The ſpecies is,

CRAMBE *Maritima.*

*Maritime, or Sea-Cabbage.*] Crambe with creeping, perennial, white roots, crowned by very broad, thick, ſmooth, grey-coloured, annual leaves, divided at the edges, and ſpreading near the ground; and between them a robuſt very-branchy flower-ſtalk a foot and half high, having all the branches terminated by looſe ſpikes of white flowers in June, ſucceeded by berry-like pods the ſize of large peas.

*Varieties.*] With deeply cut leaves—with yelloviſh flowers.

This plant and varieties grows wild on the ſea ſhores in many of the maritime counties of England, but is now cultivated in many gardens, as a choice eſculent; and the young robuſt ſhoots of its leaves and flower-ſtalks, juſt as they iſſue forth from the earth, in the manner of aſparagus ſhoots, are then in the greateſt perfection for uſe; at which period they appear white, as if blanched, which, when boiled, eat exceeding ſweet and tender; and its principal ſeaſon for uſe is April and May.

This plant may alſo be employed in the pleaſure-ground as a flowering perennial, for the ſtalks divide into fine branchy heads of flowers.

*Propagation and Culture.*

It is propagated by ſeeds ſown in any common light earth in autumn or ſpring, in the place where the plants are to remain, which, when two years old, will produce ſhoots fit for uſe, and will multiply exceedingly by the roots, and continue many years.

To cultivate this plant as an eſculent in the kitchen-garden, it is proper to have them in beds four feet and half wide, with two foot wide alleys between bed and bed, for the convenience of landing them up annually in autumn, that the ſhoots may be blanched a good length; and the lighter and more ſandy or gravelly the ſoil the better, though the plants will ſucceed tolerably in any common light ſoil of a garden. Having dug and prepared the beds the width as above, draw three ſhallow drills lengthways of each bed, and ſcatter the ſeeds therein thinly, covering them half an inch deep; when the plants come up thin the rows, leaving the ſtrongeſt plants a foot aſunder; keep them clean from weeds all ſummer; and in autumn, when the leaves decay, ſpread an inch depth of light earth from the alleys over the beds; after this, nothing more is required till the following ſpring and ſummer, when the care of weeding is to be repeated; and in autumn earth the beds from the alleys as before, but muſt now be three or four inches deep; the ſpring following, in March, April, and May, the plants will produce ſhoots fit to cut for uſe; obſerving, as the heads make their appearance through the earth, to open the ſoil a little, and cut the ſhoots four or five inches within the ground.

The ſame plantation continues many years, and the roots produce a freſh crop annually.

Their general culture is keeping them clean from weeds, and every autumn clear away all the large leaves, and land up the beds from the alleys three inches deep, to maintain a due depth of ſoil over the roots for the heads to ſhoot through, that they may be blanched at leaſt four or five inches in length; and early in ſpring looſen the top of the beds with a fork, and rake them ſmooth.

To cultivate this plant for ornament, ſow the ſeed either where you deſign they ſhall remain, or in a bed, and tranſplant them in autumn.

CRASSULA,

CRASSULA, *Craſſula*, Leſſer-Orpine, or Live-ever.

This genus furniſhes ſucculent plants for the green-houſe and ſtove, from one foot to ſix or eight in height, ornamented with oblong, thick, ſucculent leaves, and funnel-ſhaped pentapetalous flowers at the ends of the ſtalks and branches.

Claſs and order, *Pentandria Pentagynia.*

*Characters.*] CALIX is pentaphyllous and permanent. COROLLA five long narrow petals, connivent at the baſe, ſpreading and reflexed at the brim, and five ſcale-like nectariums at the bottom. STAMINA, five filaments, and ſimple antheræ. PISTILLUM, five oblong acuminated germina, five ſtyles, and obtuſe ſtigmas. PERICARPIUM, five oblong, pointed capſules, and many ſmall ſeeds.

The principal ſpecies of the Engliſh gardens are,

[1]CRASSULA *Coccinea.*

*Shrubby Scarlet Craſſula.*] Craſſula with a round, jointed, reddiſh, ſucculent, perennial ſtalk, dividing into a branchy head two or three feet high, ornamented with oblong, plane, cartilaginous-ciliated, oppoſite leaves, their baſe ſurrounding the ſtalks like a ſheath; and at the ends of the branches, cloſe umbels of beautiful ſcarlet flowers.

[2]CRASSULA *Portulacaria.*

*Shrubby Purſlane leaved Craſſula.*] Craſſula with a ſtrong, tree-like, ſucculent, perennial ſtalk, branching pyramidaly three or four feet high, having reddiſh branches, garniſhed with oboval-wedge-ſhaped, ſucculent, oppoſite leaves; and flowers growing in ſpikes, but rarely appear in England.

[3]CRASSULA *Perfoliata.*

*Shrubby Perfoliate Craſſula.*] Craſſula with an upright, ſlender, ſucculent, perennial ſtalk, branching from three to ſix feet high; lanceolate-awl-faſhioned, thick, fleſhy, cloſe-ſitting leaves, plane and canaliculated above, convex below, grow oppoſite, their baſes connated, and perforated by the ſtalk; and large cluſters of white flowers at the top of the branches.

[4]CRASSULA *Punctata.*

*Punctated-leafed Craſſula.*] Craſſula with feeble, very jointy, divided, ſucculent ſtalks, eight or ten inches long; oval-oblong, punctated-ciliated, ſucculent, oppoſite leaves; and cluſters of white flowers at the ends of the ſtalks.

[5]CRASSULA *Orbiculata.*

*Orbicular-headed Craſſula.*] Craſſula with a low, feeble, perennial ſtalk, crowned by thick ſucculent leaves, collected into a round, imbricated, ſpreading head, proliferous in many ſhort trailing ſtalks every way, terminated alſo by heads of leaves; and from the centre of all the heads, cluſters of greeniſh flowers.

[6]CRASSULA *Nudicaulis.*

*Naked-ſtalked Craſſula.*] Craſſula with long, awl-ſhaped, ſuccu ent, perennial leaves, collected into a head at the crown of the root; and amidſt them a naked annual flower-ſtalk, divided into branches half a foot high, ſurmounted by cluſters of white flowers.

All theſe plants are very ſucculent both in ſtalk, branches, and leaves; both ſtalk and branches are perennial, frequently of a reddiſh colour, and the leaves are perſiſtent; and the flowers appear principally in June, July, Auguſt, and ſometimes in winter and ſpring.

The flowers conſiſt univerſally of five long narrow petals. See the *Characters.*

The plants are all exotics, principally of Æthiopia, ſo require ſhelter of a green houſe here in winter, and muſt therefore always be kept in pots.

They claim a place in our collections of ſucculent plants for variety, though, as to their flower, thoſe of the *Craſſula Coccinea*, are conſiderably the moſt beautiful, and appear annually; but as all the ſorts having a ſingularity in their external habit, renders them worthy of attention for the ſucculent collection; they muſt be potted in light ſandy compoſt, common for other ſucculents, and retained in a ſunny part of the green houſe all winter, and very ſparingly watered; but in ſummer may place them in the full air in a ſheltered place, and in dry weather watered twice a week.

Their propagation is: the firſt four ſorts are with facility encreaſed by cuttings of their ſtalks and branches, cut off from three to five or ſix inches long, in May, June, or July, and after lying in a dry place ſome days, to ſkin over the wounded part, plant them in pots of ſandy earth, placing them in a frame, to be occaſionally ſhaded from the ſun, and ſheltered from wet; they will be rooted in ſix weeks, though, where there is the convenience of a bark-bed to plunge them in, they will root ſooner.

The other two ſorts may be propagated by off-ſets of their heads, and plant them as above.

CRA-

CRATÆGUS, Wild Service-tree, Hawthorn, &c.

The plants are of the tree and ſhrub kind, hardy, and of the deciduous tribe, valuable for œconomical and ornamental purpoſes in gardening, and of ſtature from five to fifty feet, adorned with ſimple leaves, in ſome divided, others entire, and cluſters of pentapetalous white flowers in May and June, ſucceeded by bunches of red berries in autumn.

Claſs and order, *Icoſandria Digynia.*

*Characters.*] CALIX is monophyllous, five-parted, patent, and permanent COROLLA, five roundiſh concave petals inſerted into the calix. STAMINA, twenty filaments inſerted into the calix, and roundiſh antheræ. PISTILLUM, a germen under the corolla, two filiforme erect ſtyles, and capitated ſtigmas. PERICARPIUM, a roundiſh, fleſhy, umbilicated berry, containing two longiſh hard ſeeds.

There are about ſix or eight ſpecies retained in the Engliſh gardens, ſome of which admit of ſeveral curious varieties.

The ſpecies are,

[1]CRATÆGUS *Oxyacantha.*

*Oxyacantha, or Common Hawthorn, or Whitethorn.*] Cratægus with a robuſt trunk, branching from the bottom upward to ten or fifteen feet high, the branches armed with thorns; obtuſe, nearly trifid, ſawed leaves; and numerous cluſters of white flowers from the ſides and ends of the branches, ſucceeded by bunches of dark red berries called Haws.

This is a moſt uſeful tree in forming our hedges, and it grows wild all over Europe.

Other varieties of this are,

*Double-bloſſom Hawthorn*—grows like the Common Hawthorn, only the flowers double, large, and grow in large cluſters all over the branches, of great fragrance and beauty.

*Scarlet-berried Hawthorn*—grows twelve or fifteen feet high; large leaves and flowers, and exceeding large bright ſcarlet fruit.

*Yellow-berried Virginia Hawthorn*—grows ten or fifteen feet high, having its buds in ſpring yellow, and fruit of a golden yellow colour.

*White-berried Hawthorn*—A low growing tree, producing ſmall whitiſh fruit.

*Maple-leafed Hawthorn*—grows fifteen or twenty feet high; large whitiſh leaves, large bunches of flowers, and ſhining red fruit.

*Glaſtonbury-Thorn*—grows twelve or fifteen feet high, and is like the common Hawthorn in growth, leaves, flowers, &c. only with this difference, that it generally flowers in winter, which is commonly ſaid to happen on Chriſtmas-day; it, however, has no exact time of flowering, although it ſometimes happens to be in bloom about that ſeaſon, even on the very day, yet it frequently flowers in the end of January, and in February. The ſtory of this tree blowing on Chriſtmas-day, proceeds from the tradition of the original tree near Glaſtonbury, which is ſaid to have been the ſtaff of Joſeph of Arimathea, when he came over to Britain and founded the firſt Chriſtian church; that having on that day ſtuck his ſtaff into the ground, it immediately ſhot forth and bloomed, and is ſaid to have continued to blow on Chriſtmas-day ever ſince; ſo is univerſally diſtinguiſhed by the name of Glaſtonbury-Thorn, and is retained in many ſhrubberies by way of curioſity and variety.

[2]CRATÆGUS *Aria.*

*Aria Theophraſti, Wild Service, or White-leaf-tree.*] Cratægus with an upright large trunk, dividing upward into a branchy head, growing twenty or thirty feet high, having all the young branches ſpotted with a meally down; oval unequally-ſerrated leaves, woolly and very white underneath; and large bunches of white flowers at the ends of the branches, ſucceeded by cluſters of red berries. The leaves are about three inches long, and half as broad.

[3]CRATÆGUS *Torminalis.*

*Maple-leafed Wild Service-tree.*] Cratægus with an upright large trunk, and very branchy ſpreading head, riſing forty or fifty feet high; heart-ſhaped, ſeptangular, divaricated-lobed leaves, hoary underneath; and large bunches of white flowers at the ends of the branches, ſucceeded by cluſters of large, reddiſh-brown, eatable berries.

*Other varieties are*] With round ſerrated leaves—with round ſlightly-cut leaves.

The fruit of this ſpecies being of an agreeably acid flavour, is often ſerved up in deſerts to table; and, as the trees of the common ſort grow wild in many parts, the country people gather the fruit in autumn for market, known by the name of Service berries. The leaves are three or four inches long, and three broad.

[4]CRATÆGUS *Azarolus.*

*The Azarole-thorn.*] Cratægus with an upright trunk, branching irregularly twelve or fifteen feet high; broad, obtuſe, nearly trifid, ſerrated leaves; and large white flowers in

clusters from the sides of the branches, succeeded by large, red, eatable berries, of an acid flavour.

*Varieties are*] Azarole with strong thorns—without thorns—with jagged leaves—with double flowers.

The leaves bear some resemblance to those of the Common Hawthorn, but are much larger, with broader lobes.

5 CRATÆGUS *Coccinea.*

*Scarlet Virginia Cratægus, commonly called Cockspur-Hawthorn.*] Cratægus with an upright trunk, divided upward into a strong branchy head, rising from ten to twenty feet high; large, oval, angulated-bending, serrated, smooth leaves; and very large clusters of flowers from the sides of the branches, succeeded by pear-shaped scarlet fruit.

*Varieties are*] Scarlet Cratægus with many strong recurved thorns like a cock's spur, hence the appellation Cockspur-Hawthorn—Scarlet Cratægus without thorns.

Both the varieties are fine furniture for all ornamental plantations, as they flower plentifully, and their fruit appears beautiful in autumn and winter.

6 CRATÆGUS *Crus-galli.*

*Cockspur Cratægus, commonly called Virginia Azarole.*] Cratægus with an upright robust trunk, branching irregularly ten or fifteen feet high, armed with long sharp thorns; oval-spear-shaped, sawed, smooth leaves; and large white flowers in bunches, succeeded by dark red berries in autumn.

*Varieties are*] With pear-tree leaves—with plum-tree leaves, very long spines, and large fruit—with plum leaves, short thorns, and small fruit.

7 CRATÆGUS *Tomentosa.*

*Tomentose Gooseberry-leafed Virginia Cratægus.*] Cratægus with a shrub-like stem, branching irregularly six or seven feet high, closely armed with thorns; oval-wedge-fashioned, angular, sawed leaves, woolly underneath; and small white flowers, succeeded by yellow fruit.

8 CRATÆGUS *Viridis.*

*Green-leafed Thornless Virginia Cratægus.*] Cratægus with a thornless stem and branches; lanceolate-oval, nearly trilobate, serrated, smooth leaves, green on both sides.

The flowers of all these trees, in their common state, have a corolla of five roundish petals, mostly white, appearing principally in May and June, ripen fruit in September, which are all of the berry kind, and which, in many sorts, appear very ornamental great part of winter, till devoured by the birds.

All these trees are hardy; the first three species grow naturally in England, as well as in most other parts of Europe, the *Azarole* in France and Italy; all the others are principally of American growth, but all the sorts grow freely here in any situation in the open ground.

The first species, *Cratægus Oxyacantha*, or Common Hawthorn, in its natural state, is a most valuable tree, universally known and esteemed for its great usefulness in forming hedges for fences, commonly called quick-set hedges, and for which use there is scarce any deciduous tree so well adapted, see HEDGES; and its several varieties are of great use for ornamenting our shrubberies and wilderness-works, as they will prosper any where.

All the other species and varieties have great merit as ornamental deciduous trees, and are particularly well adapted for large shrubberies and other ornamental plantations, and to form clumps in parks; and some of the large sorts to disperse singly in parks, or extensive lawns, suffering them all to retain their own natural growth.

*Propagation, &c.*

All the species are raised abundantly from seeds in the full ground; and to continue the varieties distinct, they may be budded or grafted upon stocks of the common Hawthorn, for all the sorts will readily take upon that stock, or upon one another.

By seeds, i. e. the fruits—The Hawthorn never fails to ripen Haws abundantly, which may be collected with facility from the hedges of fields, &c. in September and October; the fruit of the two Service-trees may also be found plentifully in many places; and those of the foreign sorts also ripen in our gardens; but all the sorts may be had cheap enough of the nurserymen, and the best time to sow them is soon after they are ripe; that is, in October or November, or very early in spring, in beds of light earth, either broad-cast, or in drills, and cover them an inch and half deep; but as most of these seeds often remain in the ground till the second spring, it is therefore customary with many, previous to sowing, to bury them in a heap in a trench, in dry-lying ground, for a year, as is commonly practised to the common Haws, holly-berries, and some other stony-seeded sorts, see SOWING SEED; they will be all the while

preparing

preparing for vegetation, ſo that if buried in October, November, or December, &c. ſuffering them to lie until October or November following; then ſow them, as above directed, and they will moſtly come up the ſpring after; though it is obſervable, that thoſe ſowed at once in the beds an inch or two deep, they, by having the conſtant benefit of the ſun's influence, air, and occaſional ſhowers, generally all come up freely the ſecond ſpring after ſowing, and moſt commonly ſhoot more regular and ſtrong than thoſe of the other method.

In either method of ſowing, be careful to weed the beds, and when the plants begin to appear, occaſional watering in dry weather will be of much advantage in forwarding the growth of the ſeedlings.

In the autumn or ſpring after the plants come up, ſome of the ſtrongeſt of the quick or Hawthorn ſeedlings will be proper ſets to plant immediately for a hedge, and the reſt may either then, or the year following, be tranſplanted from the ſeed-bed in nurſery-rows, to remain a year or two, or till wanted; though when they are from one to two or three years old, they are of the moſt eligible ſize to plant for hedges. See HEDGES.

Let all the other ſeedlings be alſo tranſplanted from the ſeed-bed when a year or two old, in nurſery-rows two feet diſtance, and half that in each row, to remain three or four years, or till they are from about three to five or ſix feet high, when they will be of proper ſize for the ſhrubbery, or any other plantation.

By budding, &c.—Any of theſe trees may alſo be propagated with facility by that method, which is the moſt certain way to continue the varieties diſtinct; all the ſorts take upon one another, but the Hawthorn ſtock of two or three years old is moſt commonly uſed, and the operation is to be performed in the uſual manner. See INOCULATION, &c.

Layers of the youngeſt branches of moſt of the ſorts in autumn, will often be rooted in a year or two.

Cuttings of the young ſhoots will alſo ſometimes grow.

CREPIS, Baſtard Hawkweed.

It furniſhes herbaceous ornamental plants for the pleaſure-ground, conſiſting principally of two beautiful annuals, riſing a foot and half high, having their branches terminated by ligulated compound red and yellow flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a compound flower, having a double general cup; the outer one ſhort, patulous, and deciduous; the interior one oval, furrowed, have numerous ſcales, and permanent. COROLLA, numerous, monopetalous, ligulated, hermaphrodite florets, five parted at top, and imbricated. STAMINA, five ſhort filaments, and cylindric antheræ. PISTILLUM, a germen, ſmall ſtyle, and two reflexed ſtigmas. PERICARPIUM none. SEMEN, one ſeed crowned with down under each floret.

There are ſeveral ſpecies, but not more than two of any great merit, or that are commonly retained in the Engliſh gardens, which are annuals, and called ſimply Hawk-weed, but ſhould be Baſtard Hawk-weed.

The ſpecies of our gardens are,

[1]CREPIS *Rubra.*

*Red flowering Baſtard Hawkweed.*] Crepis with ſpear-ſhaped, jagged, radical leaves, ſpreading on the ground; between them the flower-ſtalk, dividing into many erect branches a foot and half high, having oblong, lyre-ſhaped, amplexical leaves, and every branch crowned by a large, red, compound flower.

[2]CREPIS *Barbata.*

*Barbated Yellow Baſtard Hawkweed* ] Crepis with long, ſpear-ſhaped, indented, radical leaves; between them the flower-ſtalk, dividing into erect branches a foot and half high, garniſhed with ſmall, ſpear-ſhaped, cloſe-ſitting leaves; and all the branches terminated by compound yellow flowers, with dark purple middles, having the involucrum longer than the calix, ſquamous and briſtly.

*Varieties of this.*] With deep yellow flowers —with ſulphur-coloured flowers—both ſorts having dark purple diſcs.

The flowers of all the ſorts are large, compound, of many flat florets ſpread over one another imbricatum, and, when fully blown, appear like a radiated flower, appearing in June, July, and Auguſt, extremely conſpicuous and beautiful, and are ſucceeded by plenty of ſeed, from which, if permitted to ſcatter on the ground, many plants will riſe without trouble.

Theſe plants are pretty ornaments to the borders and other compartments of the pleaſure-ground, and they grow freely in any common ſoil of a garden.

*Propagation, &c.*

The plants being annual, they muſt be raiſed annually from ſeed, which may be ſown

ſown either in autumn or ſpring; the rule is, that by ſowing in autumn, i. e. in Auguſt or September, the plants come up the ſame ſeaſon, ſtand the winter, and flower in May, June, and July; thoſe ſown in ſpring flower in July, Auguſt, September, and October.

At either of theſe ſeaſons of ſowing, it is proper to ſow them at once in the places where you deſign them to flower; therefore, in different parts of the borders, in patches at five, ten, or fifteen feet diſtance, ſow the ſeeds, five or ſix in a patch, half an inch deep, placing ſticks for marks; and when the plants are two or three inches high, thin them to three or four in each hole or patch. See HARDY ANNUALS.

CRESCENTIA, Calabaſh-tree.

It furniſhes one ſpecies of the tree kind, admitting of ſeveral varieties, all of the Weſt-Indies, &c. and retained here in our ſtoves for variety; derives its name from its fruit, called Calabaſh, which is ſometimes as large as a man's head.

Claſs and order, *Didynamia Angioſpermia*.

*Characters.*] CALIX is monophyllous, and divided into two roundiſh ſegments. COROLLA is monopetalous and irregular, having a curved gibbous tube, and erect limb, five-parted at the brim. STAMINA, two long and two ſhort filaments, and incumbent didymous antheræ. PISTILLUM, a pedicellated germen, filiforme ſtyle, and capitated ſtigma. PERICARPIUM, a large, baccaceous, oval, or bottle-ſhaped fruit, with a thin hard ſhell, and many ſeeds.

The ſpecies is,

CRESCENTIA *Cujete*.

*Common Creſcentia, or Calabaſh-tree, formerly Cujete.*] Creſcentia with an upright, robuſt, whitiſh trunk, divided at top into a large, ſpreading, regular head, from ten to thirty feet high, garniſhed with large, oblong, entire leaves, and greeniſh yellow flowers on long foot-ſtalks from the ſides of the branches, ſucceeded by large ſhell fruit of different forms and magnitude, in different varieties.

*Varieties are*] Creſcentia with long ſpear-ſhaped leaves, narrow at both ends—with broad oval leaves—with large oval fruit—with ſmall round fruit—bottle-ſhaped fruit.

Theſe fruit are of different magnitudes, from the ſize of a good orange to that of a man's head, or larger, all of which fruit have a hard and thin ſhell, filled with pulp and ſeeds; the pulp is ſoft, ſour, and unſavoury, and ſeldom eaten.

Theſe trees in this country, being always retained in pots in our ſtoves, aſſume a ſhrub-like growth, and I believe very few, if any at all, have yet flowered in theſe parts.

In Jamaica, Barbadoes, and other parts of the Weſt-Indies, the trees growing as large and ſpreading as an apple-tree, bear abundance of fruit, the ſhell of which, having the pulp ſcooped out, is as thin and light as brown paper, and ſome of the largeſt capable of holding ſix or eight pints of water, &c. and are chiefly uſed for liquor and eating utenſils.

All the varieties are propagated by ſeeds procured from abroad in the ſhells; as ſoon as they arrive take out the ſeeds, and ſow them in pots of light rich earth, and plunge them in a bark-bed; and when the plants are two or three inches high, plant them out in ſeparate ſmall pots, plunging them alſo in a hot-bed, or the bark-bed in the ſtove, where they muſt always remain, giving them the neceſſary care of other tender exoties.

CRINUM, Aſphodel Lily.

This genus furniſhes four beautiful flowery perennials of the tuberous and bulbous-rooted tribe for the green-houſe and ſtove, producing erect firm ſtalks two or three feet high, crowned each by a large umbellate cluſter of ſpathaceous, monopetalous, long, funnel-ſhaped flowers, blue, white, &c.

Claſs and order, *Hexandria Monogynia*.

*Characters.*] CALIX, a diphyllous, oblong, ſpatha-like involucrum, becomes dry and reflexed. COROLLA, monopetalous and funnel-ſhaped, having a long tube, the top deeply divided into ſix ſpear-ſhaped, concave, obtuſe, reflexed ſegments. STAMINA, ſix very long filaments, and oblong incumbent antheræ. PISTILLUM, a germen in the bottom of the corolla, ſlender ſtyle, and trifid ſtigma. PERICARPIUM, a ſuboval, trilocular capſule, having ſeeds.

The ſpecies are,

[1]CRINUM *Africanum*.

*African Aſphodel Lily, or Tuberous Hyacinth.*] Crinum with a root compoſed of many tuberous fibres, collected into a head at top, crowned by ſpear-ſhaped, plane leaves, their baſes embracing each other, and ſpread two ways; and from one ſide, round hollow flower-ſtalks two or three feet high, ſurmounted by a large umbellate cluſter of bright blue flowers.

[2]CRINUM *Aſiaticus*.

*Aſiatic Aſphodel Lily.*] Crinum with a large bulbous root, crowned by long carinated leaves;

two or three feet in length, embracing at their baſe, and ſpread every way; and from one ſide, round hollow flower-ſtalks two or three feet high, terminated by large umbellate cluſters of white odoriferous flowers, having very long tubes, and long ſegments much reflexed.

[3]CRINUM *Americanum.*

*American Evergreen Aſphodel Lily.*] Crinum with a bulbous fleſhy root, crowned by long, broad, plane leaves, embracing each other in their baſe; and flower-ſtalks two feet high, terminated by large, umbellate cluſters of white odoriferous flowers, having broad ſegments, having the tops formed on the inſide like finger-nails.

[4]CRINUM *Latifolium.*

*Broad-leafed Aſiatic Crinum.*] Crinum with a large fleſhy root, crowned by oval-lanceolate, plane, acuminated, cloſe-ſitting leaves, and flower-ſtalks two feet high, terminated by large umbellate cluſters of white fragrant flowers, ſtriped with purple.

The roots of all theſe plants are perennial; the ſtalks annual, round, thick, ſucculent, hollow, and univerſally crowned by a ſort of ſpatha protruding the umbels of flowers, each ſeparate flower formed of one long, tubular, ſix-parted petal, of great beauty, appearing at different times of the year, but more commonly in autumn, often continuing till ſpring, frequently ſucceeded by capſules, eſpecially the bulbous ſorts, in which are produced ſmall bulbs, which, planted, become proper plants.

The firſt ſort is for the green-houſe, and the other three for the ſtove, retaining them always in pots of rich light earth, obſerving to ſhift them every year after flowering, for the ſake of freſh earth, and ſeparating the off-ſets, giving occaſional waterings ſummer and winter.

*Propagation.*

The firſt ſort is propagated by off-ſets from the ſides of the main roots the end of June and July, turning them out of the pots, and ſo either ſlip or cut off the off-ſets, as you ſee occaſion, planting each off-ſet in a pot of light rich earth, and place them in the ſhade five or ſix weeks, giving water, and they will probably flower the following September, which, toward the end of October, place in the green-houſe for the winter.

The ſecond, third, and fourth ſorts, are propagated by the off-ſets of their roots, or by the ſmall caulin bulbs of their capſules; but the root off-ſets flower ſooneſt, planting them in pots of rich earth, and plunge them in the bark-bed of the ſtove until they begin to flower, when they may either be placed upon the ſhelves, or permitted to remain in the bed, as convenient.

It is proper to ſhift or tranſplant the roots of all the ſorts every year or two, at their period of reſt, for the ſake of freſh earth, and ſeparating the off-ſets.

CRITHMUM, Samphire.

The plants are hardy, herbaceous, ſucculent perennials, both eſculents, and for variety, riſing two feet high, terminated by yellow umbels.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, umbelliferous flowers, having a many-leafed general involucrum. COROLLA, a uniform general umbel, the florets of five petals. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, a germen under each floret, two ſtyles, and reflexed ſtigmas. PERICARPIUM none. SEMINA, a compreſſed two-parted fruit, and two ſeeds.

The ſpecies are two, but the principal one is,

CRITHMUM *Maritimum.*

*Common Maritime Samphire.*] Crithmum with a fibrous penetrating root; thick, ſucculent, branchy ſtalks, two feet high; winged fleſhy leaves, of many ſmall, ſpear-ſhaped, fleſhy lobes; and round yellow umbels of flowers at the top of the ſtalk and branches.

The plants grow naturally on the ſea-coaſts among the gravel and rocks; its leaves are an excellent pickle, uſed for ſauces, and are by many eaten raw in ſallads, is of a ſaltiſh reliſh, palatable, and comfortable to the ſtomach, and is brought by the ſimplers in great plenty to the London markets.

To propagate this plant in gardens, either as an eſculent, or for variety, ſow the ſeeds in ſome gravelly, ſandy, or rocky ſituation, half an inch deep; the plants will come up, and endure many years.

They may alſo be encreaſed by parting the roots.

CROCUS, Saffron, but commonly called *Crocus.*

The plants are very low, flowery, ornamental perennials, of the bulbous-rooted tribe, valuable for ornamenting the fronts of our borders at early ſpring and late in autumn; for there are vernal and autumnal ſorts, of each many varieties, all of which are acaulis, ſo that the flowers and leaves riſe directly from

from the root, attaining only from about three to five or ſix inches high.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX, a monophyllous ſpatha COROLLA is monopetalous, with a long erect tube, and the limb deeply divided into ſix equal, oblong, erect ſegments. STAMINA, three filaments ſhorter than the corolla, and arrow-pointed antheræ. PISTILLUM, a roundiſh germen under the corolla, ſlender ſtyle, and three twiſted ſtigmas. PERICARPIUM, a roundiſh, trilobate, trilocular capſule, containing roundiſh ſeeds.

Modern botaniſts admit of but one real ſpecies of Crocus, which however comprehends many beautiful varieties, and the following deſcription of the original ſpecies ſerve for all, in reſpect both of the root, manner of growth, mode of flowering, general habit, and ſtature of the plants; only ſometimes by culture, the bulbs will encreaſe in magnitude, the leaves in breadth, and the flowers larger; ſo that the main difference of the numerous varieties is in the colourings of the flower, and the times of flowering, ſpring and autumn; obſerving, that although the autumnal Crocus is probably the original varieties, the ſpring Crocuſes are conſiderably the moſt numerous.

They may be divided into two claſſes, the autumnal and ſpring flowering.

The ſpecies is,

CROCUS *Sativa.*

*Cultivated Saffron, or Crocus.*] Crocus with a ſmall, roundiſh, brown, bulbous root, compreſſed at bottom; and directly from the root iſſue many long, narrow, deep-green leaves; and amidſt them the flowers, all protruded from a thin, univalvular, radical ſpatha; the tube of the flower long, ſtanding on the root, and ſerving as a foot-ſtalk to the limb or upper part, which is erect, ſix-parted, widens gradually upward, and grows from about three to five or ſix inches high.

Varieties of the *Crocus Autumnalis* are as follow: the firſt of which is the original Crocus, or Saffron.

*Saffron Crocus (Crocus Officinalis)*—A long-tubed blueiſh-purple flower, having its three *ſtigmata* of a fine reddiſh-golden colour; which part is the officinal Saffron: hence the name.

Autumnal ſmall blue Crocus—deep blue—ſky-blue——whitiſh-blue——many-flowered whitiſh-blue—purple—large ruſh-leaved purple—and autumnal white Crocus—autumnal yellow Crocus.

All theſe varieties of *Crocus Autumnalis* flower about the beginning of October, but never furniſh ſeeds here; they are very beautiful in patches in the fronts of borders, or in beds by themſelves, and very proper autumnal ornaments for gardens of every extent, as coming into full bloom at a ſeaſon when moſt other flowers are on the decay; and they grow freely in any common ſoil, and, although they produce no ſeeds in England, they encreaſe in tolerable plenty by off-ſets of the roots.

The flowers of theſe commonly appear before the leaves, which, when the flowers fade, continue their growth, remain all winter, and decay in May following, when is the time to remove the roots, which ſhould be every two or three years.

Varieties of Vernal or Spring Crocus are,

*Yellows.*] Small yellow Crocus—large yellow Crocus—golden-yellow Crocus—yellow black-ſtriped cloth of gold Crocus—yellow purple-ſtriped Crocus—double cloth of gold Crocus.

*Whites.*] White Crocus—white purple-ſtriped Crocus—white purple-bottom Crocus——white black-ſtriped Scotch Crocus——whitiſh cream-coloured Crocus—whitiſh aſh-coloured Crocus—little narrow-leafed white Crocus—white blue-ſtriped Crocus.

*Blues.*] Small blue Crocus—large deep blue Crocus—blue purple-ſtriped Crocus—blue violet-ſtriped Crocus—pale-blue purple-bottom Crocus.

*Purples.*] Small purple Crocus—large purple Crocus—ſtriped purple Crocus.

*Polyanthus Crocus*—having many purple-violet white-ſtriped flowers.

All theſe beautiful varieties of *Crocus Vernalis* flower in February, March, and April, and ripen ſeeds in May; they are all very ornamental ſpring flowers, and valuable for their early appearance, when very few other flowers are to be ſeen, and are ſo hardy, that they will grow almoſt any where, and rear their flowery heads even when chilling colds prevail, and, where duly diſpoſed along the fronts of borders or clumps, make a fine ſhew a month or ſix weeks; and they encreaſe abundantly by off-ſets of their roots, as well as furniſh ſeed for raiſing new varieties.

The flowers and leaves of all theſe ſpring varieties generally riſe nearly together, though the flowers rather appear firſt; the leaves continue their growth till May or June, when they wither, and this is the time to remove the

roots, which is neceſſary every two or three years, to ſeparate the numerous off-ſets. See BULBOUS ROOTS.

*Planting, Culture, Propagation, &c.*

In reſpect to the planting and culture of all the varieties, both of the autumnal and vernal Crocus, for ornament in gardens, they may all be planted in any of the common borders, &c. without any other preparation than common digging, and a blunt-ended dibble is to be uſed in planting: the following is the general management of both the claſſes of varieties, i. e. autumnal and ſpring-flowering.

Autumnal Crocuſes —Theſe varieties may either be planted in beds by themſelves, in rows nine inches diſtance, or in patches along the fronts of borders, as directed for the ſpring Crocuſes.

The bulbs for planting may be had of all the nurſerymen for two or three ſhillings per hundred.

The beſt ſeaſon to plant them is in July or Auguſt, obſerving, in either of the above methods of planting, to ſet the roots about two inches deep; they will flower in October following, and continue to flower annually at the ſame ſeaſon, obſerving, they may remain undiſturbed three years, when it is proper to take them all up, to ſeparate the ſmall off-ſets, and freſh dig the ground, &c. which ſhould be done in June, ſelecting the largeſt and roundeſt roots, to plant for the future bloom; theſe ſhould be planted again early in Auguſt, that they may blow in due perfection the following October.

Their general propagation is by off-ſets, as above; and from a few bulbs of each ſort you will ſoon have plenty, by means of an annual encreaſe.

Vernal or ſpring Crocuſes.—Theſe are often planted in a ſingle row cloſe along the edges of beds or borders; but to have them effect as great a variety, and as grand a ſhew, as poſſible, I would adviſe planting them in patches of different-coloured varieties alternately, both along the front of the borders, and towards the middle, or in the fronts of ſhrubbery clumps; ſo in patches of five or ſix inches diameter, plant five, ſix, or eight roots; and the diſtance of the patches may be, for thoſe in the front, from eighteen inches to three feet diſtance, and thoſe towards the middle of the borders ſhould be at the diſtance of five or ſix feet, and, in general, about two inches deep.

The bulbs of all the varieties are ſold by the nurſerymen and ſeedſmen, from ninepence to three ſhillings per hundred, according to the ſorts; or a hundred, including ſome of every ſort, for three ſhillings.

The ſeaſon for planting them is September, October, and November, though it may be performed, any time in open weather, from September to February; obſerving, however, thoſe planted before Chriſtmas flower conſiderably the ſtrongeſt, obſerving the method of planting above directed.

The roots may remain two or three years without being removed, though, as the roots in that time will be encreaſed by their off-ſets into large bunches, it is proper to take them up to ſeparate them; the proper time is May or June, when the leaves wither, obſerving to ſeparate the large from the ſmaller; and after being dried and cleaned, put them up till the planting ſeaſon, as above-mentioned, when the larger ones are to be planted in the borders, as before, and the ſmall ones, if wanted, may be planted in a bed, in rows ſix inches aſunder, to remain a year or two to grow larger, when they will be fit for your borders, or for ſale.

The propagation of all the tribe of ſpring Crocuſes are effected plentifully by off-ſets, as above obſerved; and from a few bulbs of each variety, you may in two or three years have a large encreaſe; and thoſe who incline to try for new varieties may have recourſe to ſeed, as directed for *Colchicums*.

In moſt gardens it is cuſtomary to cut off the long green leaves of the Crocus ſoon after the flowers decay, but this is injurious to the growth of the bulbs, and is done principally becauſe the leaves, becoming long and ſtraggling, have a littering appearance at the edge of the borders; but if this appearance could be diſpenſed with, and the leaves permitted to remain till they wither, it will nouriſh and prove beneficial to the roots, as will be obvious in their future bloom.

CRUCIFORMIS *Flos*, a Cruciforme, or Croſs-ſhaped Flower; a flower compoſed of four equal petals, which ſpread at top on their claws four different ways, in form of a croſs; ſtock-gilliflower, rocket, candy-tuft, lady's-ſmock, and honeſty, furniſh examples.

CUCUMIS, Cucumber, and the *Cucumis Melo*, the Melon.

The Cucumber and Melon, though vaſtly different in the external habit of their fruit, the characters of their flowers are exactly the ſame;

ſame; ſo the plants are conſequently both ſpecies of the genus *Cucumis*, very tender annuals of trailing growth, valuable for their moſt excellent fruit.

Claſs and order, *Monœcia Syngeneſia.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant, having each a monophyllous bell-ſhaped cup, terminated by five awl-ſhaped briſtles. COROLLA, is in both ſexes monopetalous, bell-ſhaped, divided into five oval rough ſegments, and adheres to the calix. STAMINA, in the males, three very ſhort connivent filaments inſerted into the calix, two of them bifid at top, and narrow antheræ, creeping upward and downward, adhering to the outſide. PISTILLUM, in the females, an oblong germen under the corolla, very ſhort ſtyle, crowned by three thick, gibbous, tripartite ſtigmas. PERICARPIUM, a fleſhy, oblong, trilocular fruit, and numerous, oval, acute, compreſſed ſeeds.

The Cucumber and Melon have, by moſt authors heretofore, been treated as diſtinct genera; but the Linnæan ſyſtem determines them to be of the ſame genus, and in which we muſt therefore alſo range them, though, for diſtinction ſake, under two ſeparate heads; firſt, the Cucumber, *Cucumis Sativa*; ſecond, the Melon, *Cucumis Melo.*

*Firſt Head.*

*Cucumis Sativa, or Garden Cucumber.*

Of the Cucumber there is but one real ſpecies, but of which are ſeveral curious and valuable varieties of the fruit; and as to the plants, they are herbaceous trailing annuals and exotics of moſt delicate tender temperature, unable to endure the open air here, except about three or four months in the heat of ſummer; and to raiſe them in early perfection, requires the aid of ſubſtantial hotbeds, under frames and glaſſes; and the culture of them, at an early time, being eſteemed a moſt curious branch of gardening, it excites an ambition in moſt gardeners to excel each other in their production as early in the ſpring as poſſible.

The ſpecies is,

CUCUMIS *Sativa.*

*Cultivated, or Common Cucumber.*] Cucumis with roots compoſed of numerous, long, ſlender, white fibres; long ſlender ſtalks, very branchy at their joints, trailing on the ground, or climb by their claſpers, adorned at every joint by large angular leaves, on long erect foot-ſtalks; and numerous, monopetalous, bell-ſhaped, five-parted, yellow male and female flowers, at the ſame, or different joints, the females ſucceeded by oblong rough fruit.

Varieties are as follow:

*Common Rough Green Prickly Cucumber*—A middle-ſized fruit about ſix or ſeven inches long, having a dark-green rough rind, cloſely ſet with very ſmall prickles; the plant is of the hardieſt ſort, bears plentifully in ſummer, but does not ſhow fruit early, ſo is not proper for frames.

*Short Green Prickly Cucumber*——A ſhort fruit three or four inches long, the rind rather ſmooth, and ſet with ſmall black prickles; is valuable principally for being one of the hardieſt and early ſorts; that is, as to early, the plants frequently begin to ſhew fruit at the firſt, ſecond, or third joint, whereby we may expect fruit in perfection much ſooner than from ſuch plants that do not ſhew fruit till they advance ſeveral joints in length.

*Long Green Prickly Cucumber*—A long handſome fruit, from about ſix to eight or nine inches long, rather thinly ſet with prickles; the plants are remarkably good bearers, and as there is an early and late ſort, it is conſiderably the beſt variety of Cucumber for the main crops, both in the frames and handglaſs, as well as in the open ground for picklers.—Variety of this with white fruit.

*Early Green Cluſter Cucumber*—A ſhortiſh fruit, remarkable for growing in cluſters, and appearing early.

*Long Smooth Green Turkey Cucumber*—The plants are ſtrong growers, with very large leaves, and long, ſmooth, green-rinded fruit, without prickles, obtaining from ten to fifteen inches in length.

*Long Smooth White Turkey Cucumber*—The plant a ſtrong grower, and ſmooth-rinded fruit, without prickles, from ten to fifteen inches long.

*Large Smooth Green Roman Cucumber*——A ſtrong growing plant, and very large, long, ſmooth, green fruit.

*Long White Prickly Dutch Cucumber*——A white fruit, eight or ten inches long, ſet with ſmall black prickles; the plants but bad bearers in England.

Of the above varieties, the firſt four are conſiderably the beſt bearers in this country, and the only ſorts to be depended on, both for the early and main crops, and the Long Green Prickly ſort moſt of all; the laſt four varieties being, for the general part, but indifferent bearers, are improper to be employed

either for an early, or any general ſummer crop; but as the fruit is ſingularly large and beautiful, a few plants of each ſort ſhould be admitted in the ſummer crops, under the hand-glaſſes, &c. or in the common ground, among the late crops.

All the above ſorts, though only varieties, yet by care in raiſing each reſpective ſort in ſeparate beds, or ſo as the farina of the flowers of the different ſorts may not impregnate each other, they will continue tolerably permanent; but without this care they in time will vary to one another.

The flowers of all the varieties of *Cucumis* are monoecious, i. e. male and female apart on the ſame plant, either at different joints, or both ariſing at the ſame joint; the male flowers are thoſe commonly, but erroneouſly, called, falſe bloſſoms, and are often pulled off; but they are ſo far from being falſe or uſeleſs, that without their vicinity and aſſiſtance, no fruit can be expected; for they contain upon their antheræ the *pollen*, or ſecundating golden powder, ſo eſſentially neceſſary for the impregnating the ovary of the female flower, by which only the fruit ſets, ſwells to maturity, and produces fertile ſeeds: both male and female flowers are diſtinctly obvious, both before and after they open; the male flower ſtands immediately upon the top of its foot-ſtalk, without any appearance of germen or fruit under it; the female flower diſcovers the germen or embrio fruit immediately under its baſe, ſo that the flower ſits cloſe upon the top of the fruit, as is apparent even from its firſt iſſuing from the branch, when not ſo big as a very ſmall barley-corn: from the firſt appearance of the miniature fruit till its maturity, i. e. fit to cut for the table, it takes up generally from about eighteen to one-and-twenty days growth.

Cucumbers at an early ſeaſon are highly valued, and are eſteemed almoſt the greateſt rarity of a garden; principally, becauſe the plants being of ſo extremely tender and delicate nature, as to require conſiderably more attention and ſkill in their early culture than any other eſculent of our kitchen-garden collection, except the Melon, which is nearly of the ſame temperature, and both of which, in the article of hot-bed culture, afford opportunities for a gardener to diſplay his abilities, and raiſe his reputation, as eminent in his profeſſion.

What is to be underſtood by early Cucumbers, is principally ſuch that arrive to perfection in February, March, and April, and is performed by hot-beds, under frames and glaſſes, begun about Chriſtmas; though, to have Cucumbers in May, June, and July, the aid of hot-beds and glaſſes are alſo requiſite, made at, or from about Candlemas till May; but in the beginning of June, when the weather becomes warm and ſettled, the ſeeds will grow in the full ground, and the plants will bear the full air till the end of September, after which time the cold nights ſoon deſtroy them; ſo that if the fruit is required after that time, the plants muſt be protected by frames, &c.

*Obſervations on their General Culture.*

As to the propagation of Cucumbers, the plants being annual, muſt of courſe be raiſed every year from ſeed, and the ſeaſon and order of ſowing is, either in hot beds, any time from about Chriſtmas till May, or in the full ground in the latter end of May, or beginning of June, obſerving, that, as the plants rarely ſucceed in the open air before June, all intended to be raiſed before that time require more or leſs artificial heat, and ſhelter of frames, glaſſes, &c.

By artificial heat in the culture of theſe plants, may be comprehended not only that of dung hot-beds, the moſt common method, under common garden-frames and lights, hand or bell-glaſſes, &c. but alſo that of ſtoves, effected by bark-bed heat and actual fire; and in which departments the plants may be raiſed at almoſt any ſeaſon: dung hot-beds, however, under frames, &c. are the moſt ſucceſsful, and beſt for any general early crop; but we ſhall exhibit both methods in their proper place.

The particulars to be materially obſerved, relative to the times of ſowing and having Cucumbers for uſe, is; to have Cucumbers early, i. e. in perfection in March and April, it is performed by hot-beds, under frame and glaſſes, begun about Chriſtmas, or between that and Candlemas; or to have them come in for uſe in May, the ſame aid is alſo requiſite, beginning in February or March; and even when they are not required till June and July, the aid of moderate hot-beds are likewiſe neceſſary, made in April, or beginning or middle of May, either under frames, or hand or bell-glaſſes, or thoſe made in May might be be covered with paper lights, in default of others; but for late crops, to come into uſe in Auguſt and September, no artificial

ficial heat nor covering is neceſſary, as, in the end of May, or beginning of June, when the weather is become ſettled and warm, the ſeed may be ſown in the full ground, and the plants will come up, and attain a bearing ſtate in two months; but to have Cucumbers from the earlieſt to the lateſt period, ſome endeavour to have them fit to cut about Chriſtmas, by beginning with a moderate hot-bed in October; and ſome are ambitious of having them for the table the year round, ſo continue ſowing every month in the year: it is, indeed, often eaſier to have Cucumbers at Chriſtmas, than a month or two later; and it is much eaſier to have them in April and May, than in February or March, and leſs dung for hot-beds, as well as leſs attendance, is required: however, to have good general crops from ſpring till autumn, three different principal crops are generally raiſed at three different times, from about Chriſtmas or Candlemas till June; the firſt, or earlieſt, to be in hot-beds, under frames and glaſs lights; the ſecond, or middle crop, alſo in hot-beds, under hand or bell-glaſſes, &c. and the third, or lateſt crop, is in the common ground; each of which crops is exhibited ſeparately.

By the above hints you will readily judge of the time to begin Cucumber-framing, according to the times the Cucumbers are required for uſe, or according to your convenience in reſpect to frames, glaſſes, dung for hot beds, mould or earth, &c. for unleſs you are properly accommodated with theſe materials, you ſhould never attempt having Cucumbers very early; for, as above hinted, it is much eaſier to have them in April, May, and June, than in February and March.

The principal materials neceſſary in the early culture of theſe plants in dung hot beds, under frames and glaſſes, &c. are as follow.

For the early crops, frames and lights of two or three different ſizes, for the ſame number of different hot-beds; that is, a ſmall frame of one light for the ſeed-bed, another of larger dimenſions, or a two-light one, for the pricking out or nurſery-bed, and one or more two-light, or three light-frames, for the final or fruiting hot-bed; each frame furniſhed with glaſs lights perfectly wind and water-tight. See FRAMES.

For the middle crops, for hot-beds made in April and May, hand-glaſſes, either the ſquare ones laid in lead, or bell-glaſſes, or, in default of theſe, oiled paper frames. See HAND-GLASSES.

Horſe ſtable-dung for making the hot-beds is a principal article; procure ſuch that is freſh, full of heat, neither too long and ſtrawy, nor too ſhort, but a due mixture of both; one cart-load, or twelve or fifteen wheel-barrows full to each light, or about thirty or forty to each three light frame, making an allowance alſo of a due portion for occaſional linings; all of which ought to be previouſly prepared by caſting it up in an heap about a week, or ten or twelve days, to forward the whole to an equal and regular fermentation, and that the violent burning quality, rank ſteam, and unwholeſome ſtench may evaporate; and if turned over once or twice, it will be more effectually prepared. See HOT-BEDS.

Earth for moulding the beds.—This ſhould be very rich, moderately light and dry, having been previouſly prepared ſome months in a compoſt heap, ſee COMPOST; or good light kitchen garden earth, enriched with rotten dung of old hot-beds, is a proper ſoil, and, if blended with a moderate portion of fine, light, freſh loam, properly incorporated, it will invigorate its vegetative quality, preparing the whole in an heap, as above, three or four months, at leaſt, before uſing it; likewiſe obſerving, that before uſing the mould for the hot-beds, a due quantity ſhould be wheeled into a dry covered ſhed, open to the ſun and free air, to be defended for a fortnight or three weeks, to have it of a moderately dry temperament, which is moſt neceſſary in early framing; and, when the mould is to be uſed, it is not adviſeable to ſcreen it, only clear out large ſtones, and break the clods as ſmall as poſſible with the ſpade, as ſifting or ſcreening would render it too compact for the tender fibres; beſides it is apt to bind, and by lying too cloſe to confine the ſteam, is more apt to burn at bottom, by the heat of the dung of the hot-bed.

Mats of baſs, reeds, or ſtraw, are neceſſary for covering the glaſſes of the hot-bed on nights, and all bad weather; but baſs mats are the moſt convenient and effectual covering. See MATS.

Small pots (thirty-two's and forty-eight's) are alſo neceſſary in early Cucumber culture, both for ſowing the ſeed in occaſionally, and for pricking the ſeedling plants in, three or four in each pot, whereby the plants may be occaſionally removed in pots, if neceſſary, from one hot-bed to another, to forward them; and alſo be more readily tranſplanted for good into the fruiting hot-bed, with the whole ball

ball of earth of each pot about their roots, ſo as not to feel their removal; and each pot of plants ſerves for one light, that is, three pots for a three-light frame.

As to the ſituation proper for the early culture of theſe plants in hot-beds, chuſe a place that fronts the ſouth, and is open to the whole day's ſun; and, if poſſible, where the ground is dry, or, at leaſt, where water is not apt to ſtand; if of a gentle declivity the better, and if encloſed, either wholly, or on the north, and eaſt, and weſt ſides, with a reed hedge or paling, to break the winds, it will be a particular advantage.

Dig no trench, as often practiſed, wherein to make the bed, eſpecially in early work, but make it entirely on the ſurface of the ground, being proper both to preſerve the bottom from being chilled by ſtanding water, and that the whole of the bed, from the very bottom, may receive the benefit of linings. If the ground is wet, or water apt to ſtand in winter, I would adviſe rather to raiſe the part gradually higher than the general level, that the moiſture, or falling water, may run away from the bed.

For the latter crops, raiſed in the open ground in June, nothing more is neceſſary than ſowing the ſeed half an inch deep in a rich ſoil; the plants will come up, and bear plentifully in Auguſt and September.

With reſpect to ſeed; in the choice of this for early crops, you will of courſe procure that of the early ſhort or long prickly ſorts; the latter is beſt for any general crop; and if you ſave the ſeed yourſelf, it is of importance to ſave it from ſome of the earlieſt fruit, that appear at the firſt, ſecond, and third joint of the main runner; and this ſeed, if poſſible, ſhould be, at leaſt, two years old before you ſow it, but if three or four the better, becauſe plants raiſed from new ſeed are apt to fly luxuriantly into vine, without ſhewing fruit in any reaſonable time, ſo are conſequently improper for early work; but if you are neceſſarily obliged to uſe new ſeed, endeavour to prepare it, by keeping it three or four weeks in your breeches pocket, previous to the time of ſowing, the drying heat of which will diveſt it of part of its luxuriant quality.

We now proceed to the culture of the different crops; and as the early culture, in hot-beds, of theſe plants and Melons, requires the gardener's atteution more than that of moſt other plants, we will enlarge on that article, ſo as to exhibit the whole proceſs according to real practice.

*Their early Culture in Frames in the Seed and Nurſery-bed.*

The time to begin the culture of early Cucumbers in frames is to be according to the foregoing obſervations, but ſome time between Chriſtmas and Candlemas is the moſt common ſeaſon to begin that work.

In the culture of early Cucumbers, it is proper, where there are good accommodation of frames and hot dung, to forward the firſt crop in three different hot-beds; a ſmall one for a one-light frame, in which to ſow the ſeed, and raiſe the plants a few days old; a ſecond, of larger dimenſions, for a large one-light, or a two light frame, by way of nurſery-bed, in which to prick the plants from the ſeed-bed into pots, to remain three weeks or a month, till their two firſt rough leaves are two or three inches broad, and when the plants have formed one joint; then to be tranſplanted with the balls of earth about their roots into a third and final hot-bed, to remain to fruit; the planting in this laſt bed gardeners call ridging out; however, if the ſeed-bed is made ſubſtantial for a large one-light, or a moderate two-light frame, it is very poſſible, by aid of occaſional linings, both to raiſe the plants, prick them down, and continue them in the ſame bed till large enough for the fruiting hot-bed.

Proceed therefore to prepare the ſeed hot-bed according to the above rules, procuring for this purpoſe hot dung, in quantity, quality, and preparation, as before directed; which being ready, then, with four ſtakes, ſet out on the ground the proper dimenſions of the bed, according to that of the frame, allowing for the bed to be rather two or three inches wider on every ſide: begin the bed by laying ſome of the longeſt dung in the bottom, afterwards take it as it comes to hand, mixing the ſhort and long well together, and ſpread it regularly on the bed, beating it firmly down with the fork as you go on, till raiſed to the proper height; obſerving, if you intend it only juſt to raiſe the plants, two feet and a half is high enough; but if deſigned both to raiſe and forward the plants large enough for the fruiting-bed, it is proper to make it three feet ſix inches high at leaſt; or, if the dung conſiſts of very long litter, four feet height in dung is not too much, ſince it will ſettle almoſt a foot in a week's time. See HOT-BEDS.

As

As ſoon as the bed is made, ſet on the frame and glaſs, keeping it cloſe a day or two to draw up the heat; then tilt the light behind, for the ſteam to paſs off.

In ſix, eight, or ten days, according to the ſubſtance of the bed, the vehement heat will begin to abate, when you may earth the bed with the prepared mould, before-mentioned, five or ſix inches thick; and next, or the ſame day, as ſoon as the earth is warm, ſow the ſeed, drilling it in near half an inch deep.

But if you are in haſte to forward your plants as much as poſſible, or that you would uſe only one hot-bed both for the ſeed and nurſery-bed, let the bed be made ſubſtantial, as before obſerved, for the largeſt one-light, or for a two-light frame, according to the quantity of plants required; ſo that by ſowing the ſeed in ſmall pots (thirty two's) you may uſe the bed the ſame, or next day after it is made, as ſoon as it begins to heat, covering it all over with any ſort of dry earth, or with old tan five or ſix inches thick, filling ſome pots with rich mould, and plunge them a little in the earth, &c. and next day the earth in them being warm, ſow fifteen or twenty ſeeds in each; but obſerving, if there is danger of burning, draw up the pots more or leſs in proportion, as you ſee it neceſſary, to prevent the earth, &c. from being burned; and in about a week the plants will be up and fit to prick in pots, and by which time the bed will be arrived at a moderate heat.

The ſeed however being ſowed in either method, do not omit tilting the light behind an inch or two occaſionally, to paſs off the ſteam, and cover it on nights with a mat.

Thus the plants will come up in three or four days, obſerving now to admit freſh air daily, by raiſing the lights an inch or two behind, alſo occaſionally on nights, according to the rules hereafter directed, and cover every night with mats: when their cotyledons, or ſeed-leaves, are fully out of the earth, and begin to expand about half an inch in breadth, it is proper to prick them in pots (forty-eights) previouſly filled with rich earth within an inch of their rims, and placed in the frame a day before to warm, either in the ſame bed, made ſubſtantial at firſt for that purpoſe, otherwiſe in a new hot-bed, as you ſhall judge neceſſary, prepared a week before, and earthed, or covered with old tan ſix inches deep, for the reception of the pots: in either of theſe beds, when the earth of the pots is warm, proceed to prick the plants therein, raiſing them carefully out of the ſeed-bed, &c. with the fibres of their roots entire; then forming a hollow in the middle of the earth in the pots, place three or four plants horizontally at equal diſtances in each pot, covering over their ſhanks almoſt to their ſeed-leaves, ſhaking the pot gently to ſettle the earth cloſe; if the earth is dry give a very light watering with ſuch that has ſtood a few hours in the bed in bottles, to take off the chill; then directly plunge the pots to their rims in the earth of the bed, being careful that every part of the dung within the frame is covered with earth, &c. to reſtrain the ſteam from riſing immediately from the dung upon the plants; for the rank dung ſteam, when not meliorated by firſt paſſing through the earth, would prove their deſtruction.

In two or three days, at moſt, they will have taken freſh root, and begin to advance in growth, though that is often effected by theſe plants in leſs than four and twenty hours, particularly when pricked out at the above age; nor will they then require ſhading from the ſun till rooted, as is often the caſe with larger plants.

The plants being thus potted out, continue every day to tilt the lights, to paſs off the ſteam, and to admit a moderate portion of freſh air, and every night cover the glaſſes with a mat or two; give alſo occaſional light waterings, and as the plants riſe in height, mould up their ſhanks by degrees; likewiſe ſupport a due degree of heat in the bed, and in about a month the plants will be arrived at a proper ſize for ridging out.

As in the early culture of Cucumbers, the plants being tender, are liable to ſuffer by many accidents; it is therefore eligible to continue ſowing a little ſeed in the ſame bed every week, and prick ſome in pots, as before directed, that, if the preceding plants ſhould fail, theſe may ſtand, and will be a ready ſubſtitute; or, if the whole ſhould ſtand, theſe will do for latter crops, and you will have ſome to oblige a friend.

But as to the particular culture of theſe plants, after being potted in this their nurſery hot-bed, the following are the principal directions.

During the violent heat and ſteam of the bed, care is neceſſary to tilt the upper end of the lights, not only every day, but alſo occaſionally on nights, raiſing them an inch or two, or a little more or leſs, in proportion to the temperature of the bed and weather, both that the ſteam may freely evaporate, as well as for the admiſſion of freſh air, to ſtrengthen the plants, which would otherwiſe

draw up weak and yellow-coloured; but tilt the glaſſes, however, leſs in proportion on nights than the day, obſerving, in all cold piercing weather, to ſcreen the opening or tilted part of the lights occaſionally, by hanging a mat looſely from the top of the glaſſes, which will break the keen edge of the air and winds from ruſhing immediately upon the tender plants; likewiſe obſerve, that if the firſt great heat is ſo violent as to endanger burning the earth in the pots, the roots, or fibres of the plants, which you ought to examine daily; the remedy is, to raiſe up the pots a few inches, or as high from the dung as ſhall appear expedient for the preſervation of the plants; and when the vehemence of the heat ſubſides, they may be plunged again to their rims, obſerving alſo, when the heat is moderate, to raiſe the glaſs for the admiſſion of air, &c. only occaſionally in the day time, from about nine or ten in the morning in winter and early ſpring months, till two, three, or four in the evening, according to the heat of the bed, and as the weather is more or leſs mild and ſunny, always ſhutting down the glaſſes cloſe before ſun-ſet; cover the lights with mats every evening about four or five o'clock, or a little ſooner or later, according to the earlineſs, or advanced period of the ſeaſon and temperature of your bed, &c. uncover each morning about eight, or a little ſooner or later, according to the above rules, obſerving, that during the firſt greateſt heat of the bed, a ſingle mat thick is ſufficient covering; but as the heat decreaſes, augment it to two or three, but never let the ends of the mats hang down conſiderably over the ſides of the frame and bed, which would draw up a violent ſteam, and promote burning, and, at any rate, would ſtifle the plants, draw them up weak, and occaſion them to aſſume a yellow hue.

Water in moderate ſprinklings may be neceſſary once in three, four, five, or ſix days, as you ſhall ſee occaſion, by the mould drying in the pots, and according to the heat of the bed, and as the weather is more or leſs ſunny; obſerving, that ſunny days are to be preferred for the application of this element, and during the winter and early ſpring months, from about eleven to one or two o'clock is the proper time of day to perform the work; the water for which purpoſe ſhould be ſoft, i. e. either pond, river, or rain-water, and ſhould either be previouſly placed in bottles within the frame of the hot-bed a few hours, juſt to take the chill off, or prepared to a proper temperature, by warming a little over a fire to mix with the reſt, but by no means let it be warmer than juſt to take off the chill.

According as the ſhanks of the young plants riſe in height, add a ſmall portion of fine dry earth round them, repeating it occaſionally till the vacant ſpace in the top of the pot is filled, being careful to have ſome fine rich earth in the frame to warm for this uſe, adding it by degrees, and the plants will emit roots all the way along their ſhanks, as far as they are thus landed up, which will prove of no inconſiderable advantage to their growth.

In regard to the heat of the bed, it muſt all along be preſerved in a due temperature by proper linings round its ſides. But, in the firſt place, that in a week after the bed is made, when the vehement heat abates, it is proper to lay ſome dry ſtraw, waſte hay, or dry fern, around the ſides, near a foot wide, and as high as the bed, and a little way up the frame, which will prevent driving wet, and piercing cold winds from penetrating, to chill and occaſion a ſudden decay of its heat.

But when the heat begins naturally to decline, which in a ſmall bed often happens in about a fortnight, or three weeks, after it is made, then the ſtraw, &c. muſt be removed from the back and front of the bed, ſubſtituting in its ſtead a lining of well-prepared hot dung, working it about eighteen inches wide at bottom, ſloping it gradually upward, and raiſe it three or four inches higher than the dung of the bed, to allow for ſettling, covering the top with two inches depth of earth cloſe up to the ſides of the frame, to keep down the ſteam, which might enter the frame, when the glaſs is opened to give air, and injure the plants; for all rank ſteam, coming directly from the dung upon theſe plants, will ſcald and deſtroy all the leaves it encounters in its direction: this dung lining will revive the declining heat of the bed, and continue your plants in a healthful growing ſtate. In ten or twelve days after, you may line the other ſides of the bed, if it ſhall ſeem neceſſary, otherwiſe defer it longer; and if the ſeaſon ſhould prove very wet or ſnowy, lay ſome dry litter around the frame, upon the top of the lining, to ſhoot off the water.

In the courſe of lining the bed, have a watchful eye againſt burning or ſteaming your plants, as a freſh dung lining often promotes a new violent heat and ſteam; you muſt therefore obſerve the precautions above hinted,

hinted, of raiſing up the pots of plants, if neceſſary, and tilting the light in proportion.

As the plants, when firſt potted out, conſiſted only of the two ſeed-leaves, or cotyledons, they, in a week after, will begin to puſh from their centre the firſt proper or rough leaf, and in a few days after that, the ſecond rough leaf will advance, encloſing in its boſom other younger leaves, and the end of the firſt advancing ſhoot or runner, which in a few days ſhould be ſtopped, to ſtrengthen the plants, and promote lateral fruitful ſhoots.

The operation of ſtopping ſhould be performed when the ſecond of the rough leaves has expanded the breadth of a ſhilling; it is a ſort of pruning performed by taking off the end of the firſt runner, ariſing, as above hinted, in the boſom of the ſecond leaf; is requiſite both to ſtrengthen the plants, and to promote their putting forth lateral ſhoots or runners, to fill the bed with proper-bearing vine; for the lateral ſhoots are the only bearers to be depended on: let therefore the end of the advancing runner be carefully taken off almoſt cloſe to the baſe of the ſecond leaf, but never ſuffer more than the third rough leaf to advance before this is done, and, if performed when the end of the ſhoot is not bigger than a large pin's head, the better; and by this early ſtopping the plants at the firſt or ſecond joint, they will grow robuſt, and ſoon prepare to ſend forth fruitful runners, ſhewing fruit probably at the firſt or ſecond joint; but if the firſt ſhoot was not ſtopped as above, it would ſometimes advance two or three feet in length, without either ſending forth ſide runners, or ſhewing fruit; for the fruit are always principally to be expected from the lateral runners.

*Ridging them out in Frames.*

When the plants have two or three rough leaves near three inches broad, and the operation of ſtopping at the firſt joint has been performed, as above directed, they will be in excellent order for ridging out, as they will then be juſt preparing to emit runners.

Provide therefore, in due time, dung for making the fruiting hot-bed, the quantity proportioned to the number of lights which you intend to work, allowing, if early, a cart load, or twelve or fifteen barrows full to each light; on this occaſion your care is requiſite to have it of proper quality, as before obſerved, by mixing it well together in an heap, ſee HOT-BEDS; but in your proceedings you muſt with forecaſt make the neceſſary allowance for the time of the dung's working, and the bed coming to a proper heat, that the plants, when ready, may not wait for the bed; this premiſed, and the dung being prepared, ſtake out the bed frontways to the ſouth, the width and length in proportion to the dimenſions of the frames, and number of lights to be employed, making allowance for the bed to be ſix inches wider than the frames; and, when more than one range of hot-beds are intended, one before another, allow a ſpace of five or ſix feet between bed and bed, for lining, &c. the dimenſions being thus ſtaked out, wheel in the dung, and proceed to make the bed, firſt ſhaking ſome of the moſt ſtrawey dung along the bottom, and then mixing long and ſhort regularly together, carry on the bed evenly, building the ſides ſtraight and upright, the middle perfectly full, and form every part equally cloſe and firm, by beating it evenly down with the fork from time to time as you advance, not treading it, unleſs the dung is very long and ſtrawey indeed, raiſing the whole three feet ſix inches high, at leaſt, if early in the year; otherwiſe a yard in height will be ſufficient, eſpecially if any conſiderable range for two, three, or more frames; but if for a three-light frame only, and made any time before April, make it the full height of three feet and half, before mentioned, as it will ſettle near a foot in leſs than a fortnight; obſerving, that of whatever ſubſtance the bed, always raiſe it rather higheſt behind, finiſhing the work by ſhovelling up all the ſhort dung remaining round the bed at laſt, and lay it at top in a ridge along the middle, which, after the bed ſettles, may be levelled as you ſee occaſion; for it will be a week, ten days, or a fortnight, according to its ſubſtance, before its heat is moderate enough for the plants.

But as ſoon as the bed is made, I adviſe to ſet on the frame and glaſſes, being neceſſary both to defend the bed from great rains, and to forward it ſooner to a proper degree of heat for the reception of the plants; obſerving, when the heat riſes, to prop up the lights, to give free vent to the ſteam, at the ſame time thruſting a long ſtick or two into the bed, that by pulling them out daily, and feeling the lower part, you can readily judge of the working of the bed, from its firſt heat, till it gradually encreaſes to its greateſt height of vehemence, and thence till it becomes of a temperate degree, which, in a middling bed,

is ſometimes effected in a week or ten days, but when of a more conſiderable range, for two, three, or more frames, it is often near a fortnight, and ſometimes more, before the heat becomes temperate enough to receive the mould and plants, which muſt not be truſted in the bed while the heat is violent, i. e. ſo hot that you cannot readily bear your finger in it any conſiderable time; for it would both burn the earth and roots of the plants, and, if it even only burns the mould, the plants can never thrive; do not, however, ſuffer the heat to become too moderate before you put in the plants, for it is neceſſary there be a briſk heat to ſet them a-going at firſt.

When the bed, therefore, is become of due temperature, prepare to mould it, previouſly obſerving, that, as the bed generally ſettles unequally, it is proper, firſt to take off the frames, and level all inequalities, and ſmooth the ſurface with the back of the ſpade, and directly ſet on the frame for good; then, the better to ſecure the earth, immediately under each hill of plants, from burning, you may, where convenient, lay a ſtratum of pliable cow-dung, not too wet, on the ſurface of the bed, juſt under the centre of each light, about eighteen inches, or two feet diameter, and an inch and half thick, plaiſtering it cloſe and ſmooth; this done, proceed to mould or earth the bed. Let the earth be rich, light, and moderately dry, as formerly mentioned, then, under the centre of each light, upon the ſtratum of cow-dung, lay about three pecks, or near a buſhel of this earth, forming each parcel into a ſort of conical hillock ten or twelve inches high, at the ſame time covering the reſt of the bed, between and round the hillocks, with the ſame ſort of earth three inches thick; on each of theſe hillocks of earth you are to ſet one pot of plants, as hereafter directed, and the reſt of the bed is to be afterwards moulded up by degrees to the height of the ſummit of each hillock.

The reaſon for forming the earth in hillocks is, that if the bed ſhould diſcover any tendency to burning after the plants are ridged out, the vehemence of the heat and ſteam will more readily paſs off between the little hills, than if the bed was at once earthed all over to its proper depth; beſides, by forming it in hills, if the earth ſhould be in danger of burning, by removing ſome around near the bottom, to reduce the ſubſtance of the heaps, the ſteam will more eaſily find vent, and if the earth ſhould unavoidably burn at the baſe of the hillocks, the burnt earth can be more eaſily removed, with leſs danger of diſturbing the plants, and, at the ſame time, be replaced, with freſh mould; likewiſe, by this practice, you may venture to ridge out your plants two or three days, and in ſome beds, a week ſooner than if the bed was to be at once fully earthed; and likewiſe, by adding freſh earth by degrees round the hills, it greatly encourages the fibres of the plants.

But to proceed to planting—The bed being earthed, as above directed, immediately put on the glaſſes cloſe, and by next day the bed will have imparted a proper warmth to the mould for the reception of the plants; having directed them, in the nurſery-bed, to be potted, three or four plants in each pot, allowing one pot of plants to each of the above hillocks of earth; but previous to tranſplanting, let each pot of plants be watered a few hours before, that the earth may adhere firmly in a ball about their roots; then, to turn them out of the pots, ſpread your hand on the ſurface of the mould, paſſing the ſhanks of the plants between your fingers, and turning the pot upſide down, ſtrike the edge gently on the frame, the plants will readily come out with the whole ball of earth entire; then, making a wide hole in the middle of the hill of earth, place the plants, with the entire ball about their roots, therein, drawing the earth cloſe round, and about an inch over the top of the ball; and if the earth is moderately dry, give a little water that has the chill taken off, and, as ſoon as they are planted, ſhut down the glaſſes cloſe, to draw up the heat, obſerving, if the ſun ſhould ſhine out, and it occaſions the leaves of the plants to flag, indulge them with occaſional ſhade; but, by care in tranſplanting them from the pots with the entire ball about their roots, they will ſcarce feel their removal, ſo as to ſhrink their leaves at the approach of the ſun; if they, however, flag conſiderably, ſhade them with a thin mat, from ten to two o'clock, the firſt three or four days, or till they take root ſo firmly as to ſtand the ſun without flagging.

The plants being now ridged out, great attention is neceſſary to allow them a daily and proportionable ſhare of freſh air, by tilting up the lights occaſionally; likewiſe to cover the glaſſes every night with mats; particular care is alſo requiſite, at firſt, to guard againſt their

their being annoyed by too much heat or ſteam, and that they do not ſuffer by cold or want of heat; occaſional waterings are alſo neceſſary in moderation; the moulding up the bed round the hillocks by degrees muſt alſo be duly attended to, ſtopping the plants once more, to procure a farther ſupply of fruitful runners, and, as the runners advance in length, train them at regular diſtances, together with the care of ſetting the early fruit; and the due temperature of heat of the bed to be preſerved by proper linings, &c.

As to the article air; in this particular your care is to conſider not only the ſtate of the bed, but likewiſe the temperature of the weather, early or advanced period of the ſeaſon, or if the ſun ſhines, or the air be cloudy, wet, or foggy; and to proportion the admiſſion of air accordingly; obſerving, that wet or foggy air, even, though mild, is more unfavourable to the growth of theſe plants than froſt, provided it is accompanied with ſunſhine, and that you have proper heat in the bed, to maintain a warmth about the roots of the plants, and to warm the internal air of the frame almoſt equal to that of a hot-houſe; and, indeed, great care is neceſſary to preſerve your bed always nearly to that temperature; for the plants are rather of a more tender quality than the pine: let air, however, be admitted daily at all opportunities, when the wind is ſtill, by tilting the lights behind, from half an inch to two or three high, as your diſcretion ſhall direct, according to the rules laid down for the nurſery-bed, making an allowance, as the ſeaſon and warm weather advances, in the time of day, of beginning to open and ſhut down the lights; and be ſtill perſuaded to occaſionally hang a mat over the tilted part of the lights in ſharp weather, that the plants may at the ſame time receive a moderate ſhare of air, and the ſteam paſs off without injury; for if the cold air is too freely admitted at an early ſeaſon, it will frequently deſtroy, or greatly injure the plants; and if the lights are kept too cloſe, ſo as to confine and ſtagnate the ſteam, the danger will be equal, the plants will imbibe an infected air, and ſoon ſhew their ſickneſs by the yellowneſs of their aſpect: when there is a conſiderable heat and ſteam in the bed, air ſhould always be admitted the moſt freely, even ſometimes on nights in a ſmall degree, as obſerved of the nurſery-bed; and in ſunny weather air is to be admitted more freely than in wet, foggy, or cloudy days: in the whole obſerve, that as there are often ſeveral changes of weather in a winter's day, and even early in ſpring, your attention muſt be given accordingly, to admit either more or leſs air, or none at all, as you ſhall judge neceſſary for the benefit of the plants, being careful, for the general part, after the great ſteam has ſubſided, to ſhut down the lights always before ſun-ſet; or, if the weather changes very ſharp, foggy, or cold driving wet, let them be ſhut down an hour or two ſooner: thus continue your attention in reſpect to the admiſſion of air, obſerving, with this care, the lights are to be continued conſtantly over the plants until almoſt Midſummer, not omitting, as the warm weather advances, to tilt them high enough in proportion; and as the heat of each day encreaſes, from morning to noon, tilt them gradually higher in proportion to the power of the ſun.

Covering the glaſſes on nights with garden-mats, &c. muſt be conſtantly practiſed every evening about ſun-ſet, or a little ſooner in very cold cloudy weather, uncovering again in the morning about ſun-riſing, or a little before or after, according to the temperature or heat of the bed, or as the weather is more or leſs favourable; and in fine, warm, ſunny mornings, always uncover as ſoon as the ſun ſhines freely on the frames, for it is very beneficial to the growth and proſperity of the plants, to enjoy as much day-light as poſſible. As to the mode of covering, uſe only a ſingle mat thick at firſt, augmenting it to two or three occaſionally, and never ſuffer the mats to hang down much over the ſides of the frame, which would draw up a great ſteam, and ſtifle the plants too much, as obſerved of the nurſery-bed: by theſe rules the covering muſt be continued every night until June.

The ſtate of heat of the bed ſhould daily be examined the firſt week or fortnight after the plants are ridged out, leſt it ſhould encreaſe again ſo violent as to endanger burning the earth at the bottom of the hills, as well as the roots of the plants; by examining the bottom of the hills, the burning, if any, is generally diſcoverable, by its having a whitiſh mouldy appearance; this muſt be taken away with great care, before it encreaſes upward to reach the roots of the plants, and, if poſſible, without diſturbing them in growth, immediately adding in its ſtead a due quantity of freſh earth, keeping the bottom of the hillocks in as narrow a compaſs as poſſible, till the danger of burning is paſt, which will be in a few

few days; but if the heat ſtill threatens danger to the plants by its violence, make wide holes in the ſides of the bed, by thruſting large ſtakes into the dung in different parts, at which holes the burning heat will evaporate in ſteam, without aſcending to the top, cloſing the holes again in two or three days with dung.

The moulding or earthing the bed between the hillocks ſhould be began as ſoon as the heat becomes moderate; therefore, in a week, fortnight, or three weeks, as you ſhall judge the danger from burning is over, lay in ſome freſh earth, to be added gradually around each hill of plants, for their fibres will now advance conſiderably, and ſtriking into the freſh mould, it will greatly encourage them; but obſerving this precaution, that the earth for this purpoſe ſhould be previouſly laid a day or two, towards the ſides and ends of the bed within the frame, to acquire a due warmth before it is applied round the hills, which otherwiſe would chill the fibres; and let it be underſtood, that this mould is not to be laid all on at once, but at different times, till the whole is earthed to the height of the tops of the hills; ſo that the whole bed will be now eight or ten inches depth in earth.

With regard to preſerving the due temperature of heat in the bed, let it be obſerved, that, as ſoon as the firſt great heat and ſteam ſubſides, it will be of utility to lay ſome dry long litter, or ſtraw, waſte hay, or dry fern, around the bed and frame, eſpecially in early work; it will defend it from the inclemencies of weather, by preventing violent or driving rains, ſnow, or ſharp cold, penetrating winds, or ſevere froſt, from inſinuating into the interior part of the bed; and by which precautions the heat will be continued in fine order till it begins naturally to decreaſe, when a ſubſtantial lining of hot dung muſt be added to one or two ſides of the bed, as ordered for the nurſery bed, and as hereafter directed in its proper place.

In reſpect to watering, a moderate ſprinkling will be neceſſary about once a week or ten days, though, in ſunny warm weather, it is probable twice in that time will be requiſite, or oftener, as the warm weather advances; chuſing, in winter and ſpring, always a warm ſunny day, any time from ten to two o'clock for this operation; but, as the warm ſeaſon advances, be more early in the day, and encreaſe the quantity of water, being careful, in cold weather, to have the chill taken off, as hath been already directed of the nurſery-bed; obſerving, that early in the year it is not proper to water too freely all over the plants and young fruit, eſpecially when there is but little ſun; but rather give the water moſtly between the vine, out of the ſpout of a ſmall watering-pot, placing a piece of tyle, or oyſter-ſhell, to water on, to prevent the mould from being waſhed from the fibres, ſo removing it to different parts of the bed; but, in fine weather, water ſhould alſo be given now and then moderately all over the leaves of the plants, which will prove a conſiderable refreſhment to them. At each time of watering, in either method, always ſhut down the lights for half an hour, or an hour, particularly in the winter and ſpring waterings. When you at any time water all over the plants, obſerve, if the ſun ſhould then, or ſoon after, ſhine out with much force, give a ſlight ſhade of a mat over the glaſſes an hour or two, leſt, by its power through the lights, it ſcorch the leaves where the drops of water adhere to their ſurfaces; but when the ſeaſon is ſo conſiderably advanced, that the ſun is powerful, the general waterings ſhould be performed in a morning before nine, or in an afternoon about three or four o'clock, when the heat of the day is paſt.

Having, when the plants were in the nurſery-bed, directed their firſt pruning, called ſtopping, obſerving, if that operation was then omitted, it muſt now be done the firſt opportunity, according to the former directions.

The plants being thus ſtopped, they, in ten days or a fortnight, will each ſend forth two or three lateral ſhoots or runners, obſerving, that when theſe have advanced two or three joints in length, if they do not ſhew fruit, a ſecond pruning ſhould take place, by ſtopping each ſuch runner at the third joint; this will promote their putting forth each about three fruitful runners, i. e. ſuch that will probably ſhew fruit at almoſt every joint; for it is from the lateral or ſide runners, acquired by the firſt or ſecond ſtopping, we are principally to expect the fruit, as you will ſee by obſervation, though, in good kinds, it frequently happens that the runners produced, in conſequence of the firſt ſtopping, ſhew fruit at the firſt or ſecond joint, which is a particular advantage in early crops. According as the runners advance, conduct them along in regular directions, at equal diſtances from each other, fixing them in their proper poſition, by gently pegging

pegging them down to the earth with ſmall hooked pegs, which you will repeat occaſionally during their advancing growth, and they will ſoon ſpread all over the bed.

In three or four weeks after ridging out, the plants may be expected to ſhow fruit, though ſometimes that is effected in a week or leſs, and perhaps at the firſt or ſecond joint, when the plants are not more than five or ſix weeks old; and I have had fruit ſhew at the firſt joint, a day or two after ridging out, in the beginning of February, as big as a ſmall barley-corn, and cut the ſame fruit for the table before the month was out; for the great article at an early ſeaſon is, to ſecure and forward the firſt-ſhewn fruit to maturity, which, without a peculiar mode of culture, will turn yellow, and drop off in their infant ſtate.

When the plants therefore ſhew fruit, particular attention is neceſſary, for one thing, to the keeping up a moderately briſk and regular heat in the bed, by proper linings, &c. for a great deal depends upon this, that the plants may be continued in a ſtate of free growth, whereby the infant fruit will advance freely, and flower ſtrong; and the next thing particularly to be obſerved, is, always to perform the office of ſetting or impregnating the young fruit, according as they come into full bloſſom, by injecting the farina of the male flowers, as hereafter directed, for the male flowers moſt commonly accompany the female or fruit bloſſoms; ſo that by practiſing this, and if a good heat is preſerved in the beds, with the due admiſſion of freſh air and moderate waterings, the fruit will ſet and ſwell freely, ſo as to acquire a due ſize for the table, probably in a week or ten days, or a fortnight at moſt, after performing the impregnation; and that, if you began about Chriſtmas, or ſoon after, the firſt fruit, with due management, will be ready early in March, and from the ſame bed a regular ſucceſſion may be obtained till Midſummer, or longer.

In reſpect to lining the bed; this may probably be requiſite in three weeks or a month, or little more or leſs, after it is made, but this is according to the ſubſtance of the bed; examine, therefore, carefully, when the heat begins conſiderably to abate, and, on diſcovery thereof, loſe no time, but prepare to line the back-part as ſoon as poſſible, for the ſucceſs of early work depends on keeping up a conſtant regular heat; having therefore hot dung in due readineſs, by previouſly working it in a heap, as formerly directed; then removing the litter from the back of the bed, work up the dung lining a foot and half wide, and as high as the dung of the bed, or rather half a foot higher, to allow for ſettling, for the lining ought to be ſubſtantial, otherwiſe it will not have the deſired effect; obſerving, if the heat of the bed is conſiderably declined, you may alſo line the front, otherwiſe it will be better to defer it a week longer; and, in ten or twelve days after that, you may ſhake up the firſt lining, adding thereto a little freſh dung, which will greatly revive its heat, obſerving alſo the ſame of the front lining; and by thus alternately making, and renewing the lining, you may preſerve a fine growing heat in the bed till June, when, by the nature of the ſeaſon, the plants will ſucceed without farther aid of artificial heat, though it is neceſſary to allow them the ſhelter of the frames and glaſſes until the middle or end of that month.

At each time of lining, do not omit laying two or three inches of earth at top, to reſtrain the rank ſteam of the dung, which would riſe and enter the frame at the ſmalleſt hole or crevice, or at the opening of the lights deſigned for the admiſſion of air.

Obſerve, likewiſe, that as a freſh lining always cauſes a very copious ſteam, and ſometimes a ſtrong heat, due attention muſt be given to tilt the glaſſes in proportion.

And when you renew the lining for the laſt time in the end of April, or in May, lay ſix or eight inches depth of earth on the top, at the ſame time raiſing the frame at bottom, that the earth of the lining and bed may join, ſo as the fibres may ſhoot into the new earth; it will greatly encourage the roots, add freſh vigour to the plants, and will ſufficiently recompence you for the trouble.

Where there is more than one range of framing, if the whole ſpace between was filled up at the above time with hot dung, it would be an additional advantage to the crop.

With regard to the work of impregnation, or ſetting the fruit above-mentioned, it is a moſt neceſſary operation of art incumbent on the gardener in the early culture of theſe plants, to be done according as the flowers, both male and female, come into full bloom, and is performed by injecting the farina of the male into the ſtigmata of the female bloſſom, which is as neceſſary to the generation of plants, as the ſeed of animals is to their reſpective ſpecies. In hermaphrodite plants the male and female organs are included

cluded all within the ſame flower, and conſequently the impregnation is readily effected by nature; but all the ſpecies of *Cucumis* being monoecious plants, male and female flowers diſtinct, both, however, on the ſame plant, the male bloſſoms being furniſhed with the ſtamina, having their antheræ loaded with a golden powder or farina, deſigned by nature to impregnate the females, ſo that the conveyance of this male powder to the female flower, either by nature or by art, is abſolutely neceſſary, as, without its aid, the young fruit will conſtantly turn yellow, and drop ſoon after they have flowered: in ſummer, when the plants are fully expoſed, the gentle breezes of wind, as alſo the bees roving from flower to flower, having the farina adhering to their legs, and ſome other accidents, are ſuppoſed to convey a ſufficient portion of the farina for fecundating the females; but in winter and early ſpring, when no wind nor bees, &c. have free acceſs into the frames, ſhews the neceſſity of performing the impregnation by art to theſe plants in particular, by carrying the male to the female bloſſoms; and the following is the method.

On the day the flowers of both ſexes fully open, or the day after at fartheſt, is the proper period for performing the operation; the male bloſſoms are with facility diſtinguiſhed from the females by the rules already obſerved; therefore, at the period of growth juſt mentioned, gather ſome of the beſt male bloſſoms, and apply their antheræ to the ſtigma of the females; ſome direct whelming them down over the female flower, ſo ſtriking them with the fore finger, to cauſe them to diſcharge the farina; but the moſt certain method is, that having gathered the male bloſſom with the ſhank or ſtalk thereto, pull off the petal or corolla carefully from about the ſtamina and antheræ; then taking the ſhank of the flower betwixt your finger and thumb, apply the antheræ, or top of the ſtamina, to the centre of the three ſtigmas of the female bloſſom, and twirl it about two or three times, that it may diſcharge or inject a due portion of the *pollen* or farina, into the ſaid ſtigmata or female organs, and then caſt it away, uſing a freſh male bloſſom for each impregnation, unleſs the males are ſcarce, as ſometimes is the caſe early in the year, when one male with care may be made to impregnate two or three females, as it alſo ſometimes happens at an early ſeaſon, that a fruit bloſſom opens, and no males forward enough on the plants; in this mortifying circumſtance you muſt have recourſe to your neighbours, ſome of whoſe plants may probably be on the contrary extreme Some, in performing the impregnation, inſinuate the male organs in betwixt the ſtigmata of the females, and ſo leave it till it naturally drops out; and ſometimes they twiſt the top of the female corolla together to keep the other part in; but all this is unneceſſary: practiſe, as before directed, and caſt the male part away as ſoon as you have performed the operation, which, if well executed, and there is a good heat in the bed, the young fruit will make amazing progreſs in a few days, advancing with the flower at its extremity; and when from about three to five or ſix inches in length, is fit to cut for the table.

Always make it a rule, during the early ſeaſon, to ſet every promiſing fruit, according as they come into bloſſom; and the critical moment is, the middle of the firſt day the bloſſom opens, or the ſecond, at moſt; being careful never to water too freely over the newly-ſet fruit, eſpecially at an early ſeaſon.

Some, to encreaſe the growth of the newly-ſet fruit, ſtop the runner, on which it is ſituated, at the firſt or ſecond joint above; it may be practiſed to ſome of the earlieſt; but too frequent ſtopping occaſions a great number of weak ſhoots, and a confuſion of vine.

The importance of the above operation is ſo eſſential in the early culture of Cucumbers, that it ſhould never be omitted, as by the practice you may always make ſure of the firſt, and every fruit that ſhews, whereas, without this care, if the culture of the plants is ever ſo well conducted, no fruit will ſet till late, as by many is experienced, except by chance ſome ſtraggling bee may have crept into the frame; ſo by the fertilizing duſt ſticking to their legs, accidentally perform the operation. The doctrine, however, of impregnation, is by ſome diſputed, in reſpect to its neceſſity and efficacy; and what is ſurpriſing, the Rev. Mr. Hanbury, in his Body of Gardening, gives hints of its inutility, as unneceſſary and of no effect, advancing, that good crops of early fruit may be expected without its aſſiſtance; but this only ſhews their total want of practical experience in this very important proceſs, as well as in that of early Cucumber framing; for almoſt every eminent gardener has proved its great uſe, and was retained as a grand and uſeful ſecret, that many young gardeners, to know it, have given a conſiderable gratuity.

There

There are, however, no other plant of our gardens that requires the gardener's aſſiſtance in the above work of generation, beſides Cucumbers and Melons, and theſe only in their early culture, under frames, or in hot-houſes, where the free air, and other means, by which the fecundating function might be naturally performed, is not obtained.

The male bloſſoms, ſo eſſentially neceſſary in the above culture, are by the ignorant termed falſe bloſſoms, and are often pulled off; but this ſhould never be done at any time of year, either in hot-beds, or in the full ground, except, indeed, where they grow in great cluſters, in which caſe they may be thinned off, leaving ſufficient for ſetting the fruit; and, likewiſe, as the bloſſom in general fades, it ſhould always be cleared away, eſpecially in early frame culture.

As theſe plants generally extend their vine conſiderably all over the ſurface of the bed, quite to the ſides of the frame, frequently ſending forth runners from all their joints as they advance, inſomuch as ſometimes to occaſion a great confuſion of vine; in which caſe, if numbers of weak, long-jointed, fruitleſs ſhoots, are produced, it is proper to thin them out occaſionally, cutting them off cloſe; and where the runners in general are conſiderably crouded, thin out alſo the weakeſt, moſt irregular, and the fruitleſs ſtragglers, ſo training the main vine, and principal bearing ſide-runners, in a moderately thin and regular manner; for when the bed is greatly crouded with vine, it, by excluding the neceſſary influence of the benefit of the ſun and air, occaſions numbers of the young fruit to drop off in their minority; obſerving, however, that the regulation of the plants, as above, ſhould, if poſſible, be begun before the vines are much entangled with each other: clear off alſo all worn-out or decayed runners; likewiſe all decayed leaves, and thin the large cluſters of male bloſſom, and pick them off in general when they begin to decay.

When the ſeaſon is advanced, that the ſun ſhines with great vehemence through the glaſſes, it is proper to give occaſional ſhade of ſingle mats, an hour or two, in the middle of ſuch ſcorching ſunny days; otherwiſe, the violence of the ſun through the glaſſes might ſcorch the leaves of the plants.

As the ſummer advances, and the days grow long, the ſun powerful, and the air mild, afford your plants a large portion of air, by tilting the lights a hand's breath or more high, in the heat of the day, which ſhould be done occaſionally in front, in very hot calm days in May and June; and in very ſcorching weather, the occaſional ſhade of a ſingle mat, or a little looſe hay ſtrewed over the glaſſes, during the fierce ſun, from eleven to two o'clock, is neceſſary, leſt the violent heat through the glaſſes ſcorch the leaves and fibres of the roots; at this time do not let them want water, once, twice, or three or four times a week, according to the heat of the weather: obſerve, likewiſe, at this time, if the leaves of the plants are grown ſo large and high as to preſs againſt the lights, it is adviſeable to raiſe the frame at bottom about three or four inches, by placing a brick, &c. under each corner, making good all irregularities of the earth of the bed occaſioned by this work, filling up alſo, at the ſame time, with earth, between the mould of the bed, and that at top of the lining, for the fibres to ſtrike into, as formerly hinted; and if the leaves of the plants are very large and crouded, let ſome be cut out, ſo as to admit the air freely: likewiſe, when the ſummer is advanced to the middle of June, if the weather is warm and ſettled, the frame may be raiſed ſo high at bottom, as to admit of the end of the plants being trained from under, upon the top of the lining, being careful to cover them on nights with mats the firſt week after training them out, till hardened to the open air; and towards the end of that month, or beginning of July, may gradually expoſe the whole to the full air to take their chance for the remainder of the ſummer, though, if you would continue them in bearing as long as poſſible, it is proper to continue to defend them on nights, and all exceſſive wet weather, with the lights.

Thus far is principally the whole culture of Cucumbers in frames, according to real practice, from the ſowing of the ſeed till the maturity of the fruit for eating; and, as the early culture is to many the moſt difficult taſk in gardening, and often attended with bad ſucceſs, by not being generally underſtood, nor has been ſufficiently explained by former authors, we have enlarged the more on this head.

But before we quit this article of the frame-culture, we would juſt add, as a neceſſary hint, that, in your proceedings in early work, never depend entirely upon your firſt ſowing and planting, but continue ſowing a little ſeed occaſionally, both in the ſeed and nurſery

hot-bed, and in the fruiting bed, after ridging out, either in pots, or in the earth of the beds; ſo pricking ſome in pots, as directed before, and plunge them in the earth towards the back of the frame; and by having them of two or three different degrees of growth, they will be ready, in caſe the firſt plants ſhould not thrive, or that they are cut off by any accident, as ſteaming, burning, cold, &c. and ſome will alſo be ready for ſucceſſion crops in new hot-beds, for it is neceſſary to have at leaſt two different crops in frames, one ſucceeding the other; and, in either caſe, it is always good culture to keep up a ſufficient ſtock, if more than wanted the better, as you will have the pleaſure of aſſiſting a neighbour with a hole or two, for which there is always great requeſt in the ſpring ſeaſon.

The raiſing or planting Cucumbers in frames may be practiſed, occaſionally, any time from Chriſtmas, as before obſerved, until the middle of May; though after the middle of April the plants will ſucceed in hot-beds, under hand or bell-glaſſes, which is the common culture for the later ſummer crops, that come in to bearing in June and July, and for which crops you may ſave the expence of frames, except, however, you have ſpare frames and lights, when they will, even for theſe crops, be preferable to the hand-glaſſes.

The neceſſary quantity of framing to work for the ſupply of a family is; for the early crop, if for a ſmall family, a two, or a three-light frame, may be ſufficient for the fruiting-bed; but for a large family, three ſuch frames, at leaſt, will be requiſite for the firſt crop, and full as many for the ſucceeding one.

Early Cucumbers for market is a valuable article, eſpecially in London, as thoſe in March will often fetch thirty ſhillings a dozen from the retailers, who frequently ſell them again at double that price; and, in April, from ten to fifteen ſhillings is the common price per dozen; after which time they become plenty, and the price falls proportionably every week till Auguſt, when the natural ground crop comes in, and when a dozen ſometimes will ſcarce fetch a penny.

*Their Culture under Hand or Bell-Glaſſes.*

When intended to raiſe Cucumbers in hot-beds, under hand or bell-glaſſes, the ſeed ſhould be ſown about the middle or latter end of March, and the plants will be ready to ridge out about the middle or latter end of April, or firſt or ſecond week in May, which periods are as ſoon as theſe plants will ſucceed under theſe kinds of glaſſes, and in which they will arrive at full bearing in June and July.

The long green prickly is the moſt eligible Cucumber for this crop; ſome of the green and white Turkey kinds may alſo be ſown for variety, as alſo any of the other ſorts; but let the firſt mentioned be preferred for the main crop.

The merit of hand or bell-glaſſes in the culture of Cucumbers is, that, for a general ſummer crop, it ſaves the expence of frames and lights, as a crop of Cucumbers, to come in for uſe part of May, all June and July, may be obtained by planting, at the above-mentioned time, in hot-beds, under theſe glaſſes, without the aid of frames; ſo that perſons not accommodated with frames and lights, or do not chuſe the expence, or that they are all employed in the early Cucumber or Melon beds, which cannot poſſibly ſucceed without their protection, may, for the ſummer crop, as above hinted, have recourſe to the hand or bell-glaſſes, at the proper period, April and May, which is of much importance to thoſe who raiſe large quantities, and particularly to the market-gardeners, ſome of which, in the Neat-houſe gardens near Chelſea, in the neighbourhood of London, work 2000 holes in a ſeaſon, each hole covered with a hand or bell-glaſs; therefore theſe glaſſes, at the afore-mentioned time, being placed on moderate hot-beds, you may either ſow ſeed under them, or put in plants, but the latter is greatly preferable, having them previouſly raiſed in a nurſery hot-bed, hereafter directed, till in the rough leaf two or three inches broad, that, being ridged out, four plants under each glaſs, in the middle or latter end of April, or in May, they will fill the glaſſes with their vine, by the time the weather is warm enough, in the beginning of June, to admit of their being trained out from under them, for the vine muſt have ſcope to run, as they will not ſucceed if too much cramped within the compaſs of a hand or bell-glaſs; for which reaſon, it will not admit beginning to ridge out earlier than the middle of April, leſt the plants grow too large for the glaſſes, before the weather is warm enough to train them out; however, in default of other conveniences, you may ſow ſome ſeed in the end of March, or

or beginning of April, under hand-glaſſes, not however, where they are finally to remain, eſpecially if before the middle of the laſt-named month, but rather, if poſſible, in a ſort of nurſery hot-bed, made for one or more of theſe glaſſes, to raiſe the plants to the ſize before mentioned for ridging out at the proper time; but in default of plenty of hot dung, or plants, &c. may ſow the ſeed at once in a final hot-bed, under theſe glaſſes, eight or ten ſeeds in each, any time from about the middle of April to the middle or latter end of May, thinning the plants to four in each hole; and even by this practice of raiſing them, they will be only two or three weeks later, and will have fruit a month ſooner than ſuch that are raiſed from ſeed ſown in the natural ground the beginning of June, which rarely arrives to a bearing ſtate before Auguſt

But the moſt eligible method for raiſing plants for the hand or bell-glaſs crop is, in March aforeſaid, or very early in April, either to ſow the ſeed in the Cucumber or Melon hot-beds already at work under frames, or where there is no room, or there are no frames at work, make, about the middle, or toward the latter end of March, a hot-bed for a frame of one, two, or more lights, according to the quantity of plants required, obſerving nearly the ſame rules in making the bed and ſowing the ſeed, as directed in the frame culture: likewiſe prick the plants, when in the ſeed-leaf, either in pots, or at two or three inches diſtance in the earth of the bed; but, for the greater convenience of ridging-out the plants with balls of earth about their roots, it is more adviſeable to prick moſt of them in pots, four in each, as obſerved of raiſing them for the frames; obſerve alſo nearly the ſame rules for giving air, covering up on nights, giving occaſional waterings, keeping up the heat of the bed, and ſtopping the plants at the firſt joint, as there directed; and in about three, four, or five weeks, when the plants have rough leaves two or three inches or more broad, and beginning to ſhoot runners, they are of due ſize for ridging-out.

The moſt proper time for ridging out under theſe glaſſes is, from about the middle of April to the middle or latter end of May.

The hot-beds for this ridging out are to be of hot dung, prepared as exhibited in the framing; obſerving, that as the ſeaſon for this work is April and May, the beds need not be quite ſo ſubſtantial as is neceſſary at a more early ſeaſon, allowing, however, if in April, dung enough, if poſſible, to make the bed three feet ſix wide, and two feet and half high; though, if not made till May, two feet height in dung may be ſufficient, and, at either time, the length of courſe proportionable to the number of hand-glaſſes you deſign to work, allowing them to ſtand at three feet ſix inches diſtance, in one row along the top of each bed.

The ridges or beds are, according to the ſeaſon, to be made either entirely on level ground, or in a trench fifteen or eighteen inches deep; obſerving, if you would ridge out in April, that, as the beds will require lining in three weeks, to revive the heat, to carry on the plants till the arrival of warm ſettled weather in June, it is therefore proper to make them entirely above-ground, to admit of lining the whole of each ſide quite to the bottom; but if you do not ridge out till May, no linings will be required; and as the ground will then be warm, dry, and free from ſtanding water, it is proper to make the bed in a trench three feet wide, and near half that in depth; ſo that the bed being above half way in the ground, and the upper part to be covered on the ſides and top with the earth of the trench, the whole will aſſume the appearance of a ridge of earth, and, by being thus moulded, and all caſed over with earth, it will preſerve the heat the longer.

On conſideration, however, of ridging-out in April, conclude to make the ridge entirely on level ground; therefore ſtake it out three feet and half wide, and as long as convenient; then wheel in the dung, and work it up regularly ſtraight and upright on each ſide to about two feet and half high; but if four feet wide, and the above height, it will ſupport a more durable heat, and be of additional advantage, for the bed will ſettle a foot, and there are often many cold nights between this time and the end of May; obſerving, if more than one range is to be made, make them one before another, allowing a ſpace of three or four feet between, which may afterwards be occaſionally filled up with linings of hot dung and earth, which will prove very beneficial to the plants, finiſhing each bed, by ſhovelling up all the ſhort dung at laſt, and lay it at top.

Having thus made the ridge or ridges, they, in three or four days, will have ſettled, and the heat ariſen, then level any inequalities at top, making that part even and ſmooth, and proceed to mark out the diſtances for the

plants, and mould the places for their reception; for, as there are no frames to confine the heat and ſteam, you may always venture to ridge out within the week; the bed being levelled at top, mark out exactly along the middle thereof the places for the glaſſes and plants at three feet ſix inches diſtance; and, if the bed is very ſubſtantial, that, previous to moulding it, you may, if convenient, as a precaution, the more certainly to preſerve the earth from burning, plaiſter cow-dung an inch and half thick on the places where the plants are to ſtand, as hinted in the frame culture: having, however, marked the diſtances for the plants, lay on each of theſe places about a buſhel of rich earth in a hillock twelve inches high, and broad enough for a hand-glaſs; at the ſame time cover the other parts of the bed, between, and on every ſide the hillocks, two or three inches thick, with the ſame ſort of compoſt, and directly place a hand glaſs over each hill, ſhutting them down cloſe to draw the heat up ſoon, and cover them on nights with mats, and, when the earth is warm, put in the plants.

The next day, or day after, the earth will be ſufficiently warm for the reception of the plants; therefore, having previouſly watered the plants the day before, that the mould may cling in a ball about their roots; then removing the plants with a ball, and levelling the tops of the hillocks broad enough for each glaſs to ſtand, plant one pot of four plants in each hillock, as before directed for the frames, giving directly a little water, and put on the glaſſes, and, if they flag at the approach of ſun, afford them a moderate ſhade the firſt two or three days; but if they are carefully tranſplanted, with balls to their roots, they will not want much ſhading, and the leſs the better.

Being now ridged out, care muſt be taken to admit freſh air to the plants in the warmeſt time of every mild day, by tilting one ſide of the glaſſes, from about half an inch, to one, two, or more high, according to the heat of the bed and warmth of the weather; but ſhut down the glaſſes in due time towards evening, or ſooner, if the weather changes cold, keeping them cloſe on nights, and all very cold bad weather; and cover every night, all over the glaſſes and ridge, with mats, until June; alſo occaſionally in all hard rains.

Give alſo occaſional moderate waterings, according to the rules exhibited in the frame culture.

In a week after ridging-out, when the great heat of the bed will be abated, then begin to earth it by degrees all over, to the height of the hillocks, which will encourage and preſerve a due heat about the fibres of the plants; and if previouſly a wreath of large ſtraw-bands, made of any kind of long litter, is placed round the edge of the bed, juſt on the top of the dung, fixing them thereto ſix or eight inches high, with long ſharp-pointed ſticks thruſt into the bed, it will ſupport the ſides of the earth, ſo as to admit of moulding the bed to its full width, and will preſerve that part of the mould from being dried too faſt by the ſun and winds.

Towards the middle of May, or ſooner, if the heat of the ridges abate, and the nights continue cold, a lining of hot dung to both ſides of the bed will be of very great advantage; make this fifteen or eighteen inches wide, beating it firm on every part, raiſing it three inches higher than the dung of the bed, to allow for ſettling, and immediately earth it at top with rich earth to the thickneſs of that on the ridge; this lining will be moſt ſerviceable in a triple degree; the freſh dung will revive the heat of the bed, the earth at top affords additional ſcope for the fibres to ſtrike into, and the bed, being augmented in width, gives an opportunity of training the vines regularly to their full extent.

As the days encreaſe in heat, and the plants in growth, admit air accordingly, by tilting the warm ſide of the glaſſes in proportion, to harden the ends of the runners gradually, to be trained out from under the glaſſes, when the weather is become warm and ſettled.

In the latter end of May, or beginning of June, the plants will have filled the glaſſes with their runners; they muſt then be trained out, by elevating the glaſſes on props: this, however, muſt not be done too haſtily before the firſt or ſecond week in June, if poſſible, to retain the plants till that time under the glaſſes, for we have often very cold nights till the end of May, and ſometimes a week longer; therefore, in the firſt or ſecond week in June, according to the ſettled temperature of the weather, and advanced growth of the plants, prepare to raiſe the glaſſes on every ſide three or four inches high, on bricks, pieces of wood, or notched ſticks, and lead the runners out regularly at equal diſtances; faſten them down with hooked pegs, to ſecure them againſt the the power of winds, obſerving to continue the covering of mats every night, and all very rainy or bad weather, for the firſt fortnight after they are thus trained out from under the glaſſes; continue the

glaſſes

glaſſes alſo over them till July, or, if continued all ſummer, it will preſerve the head or main ſtem of the plants from injury of weather.

When the runners advance from under the glaſſes, if ſome dry reeds, clean wheaten ſtraw, or ſmall bruſhy or branchy ſticks, are ſpread on the ſurface of a few holes, for the vines to run upon, it will preſerve them clean, and the earth from drying too faſt; and the fruit will be better preſerved from ſpotting, which often is the caſe in wet ſummers, when they lie on the ground.

In hot dry weather, when the vines are advanced conſiderably, and in fruit, do not omit ſupplying them with water two or three times a week; though in July, when in full fruit, they, in very dry ſcorching weather, will need water every day, or even twice in a day, in the morning before eight, and in the evening after four o'clock, giving, at this time, a watering-pot full, at leaſt, of water, to each hole, watering equally all over the bed to the very outſide; and by thus preſerving a due moiſture in the earth, during the great heat of the ſeaſon, the plants will ſhew fruit abundantly, and it will ſet and ſwell ſurpriſingly faſt to maturity.

As to the operation of ſetting or impregnating the fruit, as directed for the frames; this, if you are anxious about having ſome of this crop fit to cut as ſoon as poſſible, may be performed to thoſe that firſt ſhew whilſt under the glaſſes; but after the vine is trained out into the full air, there will be no great neceſſity for taking that trouble, for reaſons already mentioned.

This crop will continue in bearing from about the end of May, or beginning of June, until the latter end of Auguſt, or till September.

But with reſpect to ridging-out theſe plants in May, as we formerly obſerved; the ridge, or hot-bed, at this time need not be more than three feet wide, and about two feet deep in dung, nor will it require lining; and therefore I ſhould adviſe to make it moſtly within the ground, in a deep trench, the earth of which will mould the bed; mark out, therefore, a trench, where the ground is perfectly rich and light, three feet wide, and in length at pleaſure; dig out the earth twelve or fifteen inches deep, or, in dry ground, a foot and half, if the goodneſs of the ſoil will admit, laying the earth in a range cloſe along each ſide, to be ready wherewith to mould the ridge; and if more than one ridge is intended, make them parallel, and allow a ſpace of four or five feet between.

The trench being ready, then wheel in the dung, and ſpread it regularly to the full width and depth of the trench, raiſing it, however, if in the beginning of the month, near two feet thick; but if about the middle, or after, eighteen inches depth in dung may be ſufficient; obſerving, in either caſe, to work it as firm as poſſible with the fork, and directly mould it all over the top nine inches thick, and mark out the places for the glaſſes, by placing ſticks exactly along the middle, at three feet and half diſtance, and then trim the reſt of the earth of the trench equally up to each ſide of the bed, cloſe to the earth at top, ſo as to cover every part of the dung, and form the whole into a broad bed five feet wide, aſſuming the appearance of a raiſed bed of common earth, trimming the edges ſtraight by line; this done, put on the glaſſes, and, at night, cover the whole with mats, to draw up the heat, and next day, or day after, the earth will be warm; then put in the plants, as before directed, give water, and ſet on the glaſſes, covering them, and the bed in general, on nights, with mats; likewiſe, in exceſſive rains, night or day, at firſt planting, otherwiſe it might chill the bed, being of moderate ſubſtance, ſo as to occaſion a total decline of its heat. As to their other culture, it differs not from thoſe ridged out in April, only the bed is not deſigned to be lined; but in all other reſpects the ſame management is to be obſerved.

Along the edges of the bed may be planted rows of coſs-lettuce, which will come off time enough for the plants to run.

Another method of ridging-out in this month (May) is, that, in caſes of ſcarcity of hot dung, inſtead of forming one continued ridge of dung, in a trench, as above directed, it may be worked in holes, one hole for each glaſs; dig therefore holes two feet wide, and twelve or fifteen inches deep, and three feet and half from centre to centre; obſerving, if you deſign more than one range, allow ſix feet between each row of holes; then let a large barrow-full, as much as a man can wheel, of good hot dung, be worked firmly into each hole; earth them directly nine inches deep, place on the glaſſes, and when the earth is warm, either put in ſeed, or rather plants, managing them as before directed; afterwards, at your convenience, dig and work

up

up the earth on each ſide the rows, ſo as to form every range of holes into a ſort of bed, five or ſix feet wide, for the vines to run upon; and along the edges of which you may plant rows of coſs-lettuce, as before obſerved.

By this method many of the London gardeners ridge out their main hand-glaſs crop, particularly thoſe of the Neat-houſes near Chelſea, where the ground is ſo rich, light, and warm, many of whom work ſeveral hundred glaſſes.

Their method is; the ground is generally planted with early cauliflowers the October before, under the hand glaſſes, in rows eight feet apart; in the ſpace between is ſowed radiſhes and ſpinach about Chriſtmas, or a little before or after, for ſpring crops; theſe come off early in May; then they make the holes there for the Cucumber, and the glaſſes being then ready at hand, and unemployed for that ſeaſon with the cauliflower, they are placed over the Cucumbers; the cauliflowers coming off in July, they, in each place, plant a trench of celery, or ſometimes rows of endive or lettuce; and the Cucumbers having done their beſt by the third or fourth week in Auguſt, and thoſe of the natural ground in perfection to ſucceed them, they are pulled up, and the ground dug, and directly ſown with winter ſpinach; and in September or October, the celery, endive, or lettuce, planted where the early cauliflowers grew, being all cleared off for market, the ground is dug, and either planted with cauliflowers again, or with ſeveral rows of cabbage-coleworts, at a foot diſtance in the rows, which will be fit for market by Chriſtmas; but theſe gardeners generally change the ground every year or two in different crops.

In ridging-out Cucumbers in holes, as above, if you place a few holes near a ſouth wall, paling, or reed-hedge, you may, in June, train the vines of the plants up againſt thoſe fences, both for the ſake of variety, and to improve the ſize, beauty, quality, and flavour of the fruit; for they are generally larger, more fair and free from ſpots, more ſolid, firm, leſs ſeedy and watery, than thoſe which lie on the ground.

By this practice you may particularly improve the long green, and white Turkey kinds, &c.

Or, if you place ſome branchy ſticks, as for peas, about three or four feet high, the plants being of the cirrhoſe climbing kind, they, with a little conducting at firſt, will aſſiſt themſelves in aſcending upon the ſticks, by means of their *cirrhi*, or tendrils, though, when deſigned to train theſe plants off the ground, they ſucceed beſt when trained againſt ſome kind of fences, either of cloſe, or of open work, and free to the full ſun.

*Raiſing them under Paper Frames.*

In default of hand or bell-glaſſes, a few holes of Cucumbers, for private uſe, may be brought to bearing in June, under ſhelters of oiled paper, either paſted on ridged or arched frames, made of lath, or other open work, four feet wide, ten long, and three high; or on ſmall open frames the ſize of hand glaſſes; or by paſting three or four ſheets of ſtrong paper together in a piece, each ſuch piece to cover one hole of plants, previouſly oiling it, as is directed for PAPER FRAMES; ſo in the beginning, or towards the middle of May, ridging out ſome plants, or, for want thereof, ſeed, on hot-beds, as before directed; then place on your frames directly, or, if you uſe only the ſheets paſted together, as in the latter method, firſt arch over each hole of plants with two or three pieces of hoops, &c. placed acroſs one another, eight or ten inches high, and place the paper over each arch or hole of plants, laying bricks, boards, or ſome other ſubſtance, to prevent them from being diſturbed by boiſterous winds; but either of the other two methods would be better than this: however, let either of theſe ſhelters remain over the plants day and night, till the middle or latter end of June, admitting freſh air occaſionally, covering every night during the cold weather with mats; alſo all times when it rains exceſſive hard the firſt three or four weeks after planting.

Under theſe temporary ſhelters, by aid of a moderate heat of dung, you may obtain Cucumbers a month or ſix weeks ſooner than any can be raiſed from ſeed entirely in the natural ground.

*Raiſing them in Hot-houſes.*

Cucumbers are often obtained in hot-houſes any time in winter, and early in ſpring, with leſs trouble ſometimes than in hot-beds under frames, not, however, always with ſucceſs of ſuch plentiful crops; but as pine-apple ſtoves are now common in moſt parts of the kingdom, it is worth trial, and if but a few very early fruit is obtained, it will compenſate for the trouble.

The ſeeds may here be ſown any time from October

October till March; though to have them as early as poſſible, it is proper to ſow in October; and for the greater certainty of ſucceſs, repeat it in November and December, and even every fortnight during winter; but let it be obſerved, that thoſe ſown about Chriſtmas, or ſoon after, will be conſiderably the moſt proſperous and ſucceſsful crops: let the ſeeds be ſown half an inch deep in ſmall pots of rich earth, that have been previouſly plunged in the bark-bed a day or two, to warm the mould, retaining the pots therein, and the plants will riſe in a few days, which, when two or three days old, prick in pots, as in the frame and hand-glaſs culture, plunging them alſo in the bark-bed, giving now and then very moderate waterings; and as to air, they can have it only in common with the other plants of this department; obſerving, as the plants advance in growth, to ſtop them at the firſt joint, as hath been already directed; and when they are juſt ready to ſhoot runners, let them be tranſplanted with the entire ball of mould about their roots, into large pots or boxes, to remain to fruit, but rather into trough-faſhioned boxes, about three feet long, a foot wide at top, nine inches at bottom, and ten inches deep, having them filled with the beſt rich light earth, and placed in the ſtove a day or two before; then plant two pots of plants in each trough, and give a little water: as to the proper ſituation in the ſtove for theſe boxes, &c. to remain, they may be tried in different parts; where there is room you may plunge one or more half way in the bark bed; others may be placed on top of the flues, elevating them upon bricks, or ſome other materials, ſo as there may be a vacancy of ten or twelve inches between the top of the flue and bottom of the boxes, both that the heat of the flues may have due vent, and that it may not dry the earth in the boxes too faſt, and the boxes being ſo elevated, the plants will be nearer the top glaſſes, which is of much importance to theſe plants for receiving the greater benefit of the ſun; and for which reaſon, if ſome boxes, or one long trough was erected near the top glaſſes, it would be of conſiderable advantage, which might readily be done by iron or wooden brackets, ſuſpended from the croſs-bars at top, and the proper place is along under the uppermoſt or back part of the top glaſſes, juſt over, or rather a little behind the back walk of the ſtove, that it may not ſhade the other plants, or water drop therefrom upon them, and that they may be nearer the warmth of the flues, fixing them at about twelve or fifteen inches from the glaſſes; in which ſituation, in this department, I have always obſerved Cucumber plants, at an early ſeaſon, to be more proſperous and fruitful than when more diſtant from the top lights; obſerving, however, that during the reſidence of the Cucumbers there, at an early ſeaſon, the uppermoſt tier of the top glaſſes muſt not be drawn down, but admit air occaſionally at the loweſt tier, or front lights.

When the plants are thus finally planted out in either of the above methods, your care is requiſite to ſupply them duly with moderate waterings twice a week, or oftener, if it ſhall ſeem neceſſary.

Likewiſe, when the vines or runners of the plants advance, fix up ſome neat laths for them to run upon, and to which they muſt be faſtened occaſionally as they advance in length.

When they ſhew fruit, practice the operation of ſetting them, as directed in the frame culture.

In this, the hot-houſe culture of theſe plants, different methods may be practiſed by way of experiment; as that of ſowing the ſeed and pricking the plants in pots, and afterwards tranſplanting them with balls where they are to remain to fruit, as already directed; or only juſt raiſe the plants, as above, till two or three days old, and tranſplant them into the fruiting boxes; or ſow the ſeed at once in the ſaid boxes, and ſuffer the plants to remain to fruit; or ſome plants might be plunged in the tan between the pines, and their vines ſuffered to run among them.

Try alſo plants previouſly raiſed in pots in dung hot-beds, under frames, till in the ſecond or third rough leaf; then tranſplant them with balls into the boxes in the ſtove.

Cucumber plants, raiſed in a common dung hot-bed in September or October, till in the ſecond or third joint, and then tranſplanted with balls into the ſtove, will ſometimes afford a few fruit in November and December.

Cuttings of Cucumbers, taken off five or ſix inches long from ſome healthful plants of the ſummer crops towards the end of September or beginning of October, planted in pots of rich light earth, and plunged in the bark-bed, will take root, and often break forth into runners, and produce fruit in November and December.

Cucumber

Cucumber plants may be raiſed in the ſtoves to a proper ſize to plant out in hot-beds under frames, where they are to fruit for the early crop, which will ſave the trouble of making a dung hot bed for ſowing the ſeed and nurſing the plants: ſow the ſeed about Chriſtmas in pots, and prick the plants into others, as before directed, and when in the firſt joint, and begin to ſhoot runners, tranſplant them with balls into the fruiting frames.

*Raiſing them in the natural Ground for Picklers, &c.*

In the laſt week in May, and firſt and ſecond in June, is the time to ſow Cucumbers in the natural ground, for picklers, &c. before which time neither the ſeed nor plants will ſucceed in the natural earth, nor open air.

This crop ſucceeds the hand-glaſs Cucumbers, and comes into full bearing the beginning of Auguſt, and continues bearing plentifully until the middle of September, either for picklers, for eating, or for culinary purpoſes; but it is from this crop that the general ſupply for pickling is commonly gathered.

Obſerve, that although we mention the laſt week in May, or beginning of June, for ſowing, it is, however, not every year that the weather is favourable enough to admit of performing this ſowing in May; for it muſt not be done before the weather is become warm, dry, and ſettled, as, if you put in the ſeed while cold or very wet weather prevails, or when the ground is cold and wet, it will ſurely rot; or, if any plants come up, they will acquire a ſtunted dwindling growth, and come to nothing; and of late years it is commonly the firſt or ſecond week in June before the ſeaſon is temperate enough for ſowing this crop: you muſt not, therefore, be too eager in ſowing before that time, unleſs the ſeaſon proves very fine and warm; but, at any rate, never put in a ſeed before the 24th of May, and then it ought to be only in a warm dry ſituation, unleſs, indeed, you have any ſpare hand-glaſſes, which you may place over the holes; but for ſome years paſt, the firſt and ſecond week in June has, for the general part, proved the moſt ſucceſsful ſeaſon for ſowing in the open natural ground.

The ſowing is to be performed at once in the place where the plauts are to remain to fruit.

Chuſe, therefore, for this crop, a ſpot of your richeſt ground, in any of the common quarters, open to the full ſun, either a clear ſpot, or, where there is none, may be ſown between crops ſtanding diſtant in rows, and are ſoon to come off the ground; as, between rows of cauliflowers, early cabbages, between wide rows of early beans, or in the alleys between onion-beds, particularly thoſe for culling, or in the alleys between beds of tranſplanted lettuces, or ſuch like temporary crops, that come off by the time the Cucumbers begin to advance conſiderably; however, where there is ground vacant from crops, in a proper ſituation, it ſhould be preferred, as the whole can be properly digged, and divided into proper beds.

The order and manner of ſowing is, if a clear piece of ground, let the whole be neatly dug, and then divide it into beds five feet wide, having a foot-wide alley between bed and bed; then along the middle of each bed mark out the holes or places for the ſeed at three feet ſix inches diſtance; let the earth in each place or mark be finely broken, and then hollow it with the hand in a baſon-like form, about fifteen inches diameter, and two or three deep; then, in the middle of each hole, drawing a little earth to one ſide, ſow ten or twelve ſeeds half an inch apart, and cover them over half an inch deep with the earth.

But when you are neceſſitated to ſow between other crops, as above hinted, you muſt be content, for the preſent, only to dig holes in each patch where the ſeed is to be ſowed, obſerving the diſtance in the row as before, and allow, if poſſible, ſix feet between each range of holes, ſowing the ſeed, as already directed, and when the crop comes off, the ground between the rows may be digged, and formed into beds, as before adviſed.

The crops ſowed in the above methods, is according to the common practice of the moſt eminent kitchen-gardeners, and deſigned prineipally for the vines or runners of the plants to be trained along the ſurface of the ground.

But as theſe plants are of the tribe of cirrhoſe climbers, nature having furniſhed them with *cirrhi*, or tendrils, ſeems to indicate that it never intended them to trail on the ground; therefore ſome may be raiſed in ſuch order, as for their vines to climb upon ſticks, &c. in the manner of peas; when this is intended, I ſhould adviſe to ſow them in drills, running north and ſouth, five feet diſtance, firſt forming with a hoe or ſpade a ſort of ſhallow flat trenches

trenches a foot wide, and one or two inches deep, the diſtance as above, and along the middle of each of theſe ſhallow trenches draw a ſmall drill a finger's breadth deep, in which ſow the ſeed, and cover it about half an inch with the mould; here, when the plants begin to run, place to each row ſome branchy ſpreading ſticks a yard high, whereon to conduct their runners, and on which they will alſo naturally aſſiſt themſelves in aſcending by means of their tendrils, and will produce plenty of fruit, which, by being elevated from the earth, will be fair, firm, and free from ſpots.

Or, if ſome are ſown on a ſunny border cloſe along under a wall, paling, reed-hedge, or any other fence, and to which train the plants, and here they will produce handſome fruit, clear, and free from ſpots, leſs watery and ſeedy than thoſe that lie on the ground, and much better flavoured, and conſequently preferable both for eating and pickling.

The above methods of ſowing, for training the plants upon ſticks, or againſt fences, is principally recommended for practice to a few in private gardens for family uſe, which would by no means be practicable in large grounds, where great quantities are raiſed for market.

The ſeed being, however, ſowed in either of the above methods, I adviſe, if very dry and hot ſunny weather, to ſprinkle the holes every day or two with water; but let this be done very moderately, only juſt to preſerve the earth in a middling degree moiſt; for, if the earth is rendered very wet, either by watering or exceſſive rains, the ſeeds are very apt to rot: preſerve, therefore, only a very moderate moiſtneſs, and, if the weather is hot and dry, the ſeed will ſprout in a few days; but if the ſeaſon is very dry, and the ſun ſcorching, the ſhade of a cabbage leaf to each hole, to prevent the earth from drying too ſuddenly, will prove very beneficial to the free germination of the ſeed, and the plants will riſe in ſix or eight days; at which time you will do well to watch the ſparrows, for theſe birds often devour the ſeedlings at a great rate, juſt as they iſſue from the ground.

But in ſowing this crop in warm dry ſeaſons, it is the practice of many of the London gardeners, that if the weather proves exceſſive hot and dry, ſo as to parch the earth conſiderably, they, previous to ſowing, chit or ſpear the ſeed, by ſoaking it in water; that is, they put the ſeed in ſoft water, and place it within a hot-bed frame, about twenty-four or thirty hours, or long enough for it to ſpear, i. e. germinate or ſprout half a quarter of an inch long, which they call ſpearing the ſeed; they then ſow it directly, giving water freely in dry weather, and the plants will often riſe in two or three days.

Another method of treating this crop is, that in cold wet ſeaſons, as it ſometimes happens, even in June, I would adviſe, where practicable, to raiſe the plants on a ſlender hot-bed in patches; and when about a week or ten days old, juſt beginning to ſhew the rough leaf, tranſplant each patch of plants with a ball of earth into the natural ground, in the places where they are to fruit, a patch to each hole; this is an eligible practice in bad ſeaſons, and practiſed by many of the London gardeners, who ſometimes raiſe plants enough to furniſh an acre or two of ground, and by that means have much better crops, and come ſooner to fruit by a fortnight than when raiſed in the common way in a cold wet ſeaſon, as above. The method is as follows.

In the laſt week in May, or firſt in June, make a hot-bed three or four feet wide, and fifteen or eighteen inches high, the length in proportion to the quantity of plants required; earth it directly about three inches deep, and ſow the ſeed: the method of ſowing is, to dot in the ſeed in cluſters in ſmall holes an inch and half apart, and half a one deep; that is, with the two firſt fingers and thumb, contracted at top, dot holes in the earth of the bed the above diſtance and depth; as you proceed, drop eight or ten ſeeds in each hole, and when the whole bed is thus ſown, immediately cover in all the holes evenly with fine earth: or, inſtead of dotting in the ſeed, as above, may draw ſmall drills ſouth and north the bed, near an inch deep, and two aſunder; ſow the ſeeds in the drills in cluſters, as before, and earth them over the ſame depth; but I would rather recommend dotting them in: then, in either method of ſowing, let the bed be directly arched over with hoops or rods, in order for covering on nights, and all bad weather, with mats; if the weather, after ſowing, ſhould prove hot and dry, give moderate ſprinklings of water, and the plants will be up in three or four days; and the ſeed being thus ſown in cluſters, the plants will riſe alſo in bunches, which, when they ſhew the rough leaf, are then fit to tranſplant; previouſly water them ſome hours before, that the earth may cling to their roots;

then proceed to take them up with the point of a hollow or ſcooped trowel, each cluſter or patch ſeparate, and with a ſmall ball, which will readily adhere about the fibres, placing the bunches of plants carefully in a flat baſket, to be carried to the place of their deſtination, which ſhould be previouſly digged and formed into holes, baſon-faſhion, as in the common method; break the earth fine, and plant one bunch of plants in each hole; cloſe the earth well about them, and give a little water, but they will not require ſhading; for being removed young, and with balls, they will not feel their removal; ſo repeat the watering occaſionally, and the more ſun they now have the better, and they will grow ſurpriſingly; obſerving, when they are fairly in the firſt rough leaf, they muſt be thinned to four of the beſt plants in each hole, as directed in the general culture following.

As to the general culture of this crop of Cucumbers, raiſed in either of the above methods, the principal articles to be obſerved are; that, if dry weather, after they are come up, let them be moderately watered every day or two, at leaſt; and when they have been up a fortnight, or when their firſt rough leaf is advancing, it is proper to thin them to four or five plants in each hole, reſerving the ſtrongeſt plants at equal diſtances, and mould up their ſhanks, preſſing it gently but cloſely about them, ſo as to ſpread the plants different ways, and give ſome water, to ſettle the earth where looſened by thinning out the ſuperabundant plants: if there are deficiencies in any of the holes, make them up with the beſt of the plants thinned out. After this, continue your care of watering in dry weather; it will be neceſſary three or four times a week, and ſometimes every day, and even twice a day, morning and evening, in July and Auguſt, when the weather is exceſſive hot and dry.

In the beginning of July, when the plants begin to run, let the holes be lightly hoed with a ſmall hoe, to deſtroy weeds, and looſen the earth; drawing a little mould about the ſhanks of the plants, preſs it gently between with the back of the hand, to ſeparate the plants as much as poſſible from each other, at equal diſtances, and in the direction you intend they ſhall run; let the whole ſurface be alſo lightly hoed, and if gently looſened two or three inches deep, as far as the plants will extend; it will greatly encourage them.

As the vines advance in length, it will be of much advantage to peg thoſe down which you deſign to run upon the ground, to prevent their being diſturbed by wind; and if ſome reeds or ſmall ſticks are ſpread for the vine to run upon, which might be readily effected to a few holes in private gardens, the plants will faſten themſelves thereto by their claſpers, and by keeping the fruit from the ground, preſerves them from ſpotting.

Thoſe which are intended to be trained to ſticks or fences, ſhould have that work begun when they are advanced near a foot long, and continue conducting the runners thereto occaſionally as they advance in length.

Be ſure, in dry weather, after the plants are conſiderably advanced, to water freely, as before hinted; and in July and Auguſt, when they come into fruit, and the weather hot and dry, to water every day.

Theſe crops come into bearing the end of July, or beginning of Auguſt, and continue fruiting in great plenty till the middle or latter end of September; but after the middle of that month the fruit is often ſpotty, very humid or watery; therefore, when the fruit is required for pickling, begin gathering for that purpoſe in Auguſt, and continue it a month or ſix weeks, or as long as the fruit continue fine and unſpotted.

For this purpoſe of pickling you ſhould look over the plants three times a week, to gather all the fruit that are fit; when they are from about two to three inches long, and not thicker than your finger, they are of proper ſize for pickling; obſerving, if poſſible, to gather them when they are dry and clean, each with its ſtalk, and the ſooner they are put into the pickle after gathering, the greener they will be, and more firm and criſp to eat, which are commendable properties in pickled Cucumbers.

The fruit for pickling ſell in the London markets from five to ten ſhillings per thouſand, though, in fine, favourable, and forward ſeaſons, I have known them ſold for half a crown or three ſhillings; it is amazing to ſee what prodigious quantities are brought to theſe markets in a morning; one gardener perhaps brings fifty or a hundred thouſand at a time for his own ſhare; they ſell them moſt commonly wholeſale to the oil-men, who pickle them to retail out in ſmall quantities to chandlers-ſhops and families.

The neceſſary quantity of plants to produce picklers for family uſe, is from about ten to

fifty or ſixty holes, according to the demand of the family; every ten holes will afford near a thouſand picklers in the courſe of the ſeaſon, i. e. from about the beginning of Auguſt until the middle of September.

Much wet weather is very unfavourable to this crop of Cucumbers; it chills the earth and fibres of the plants, which being naturally tender, they in ſuch ſeaſons neither produce fair fruit, nor a plentiful crop, nor is it of free growth, and the plants continue but a ſhort time in bearing before all the fruit of each gathering will be ſpotty, and very unſightly to the eye, watery, and ill-taſted.

But in dry warm ſummers, let them be duly ſupplied with water, and they will bear abundantly, and the fruit will be fair, arrive faſt to perfection, and continue fine till the autumn rains, or long dewy nights, towards the middle of September, chills the earth and plants, when the produce will begin to be both ſcanty, deformed, and ſpotted.

*Of having them late in Autumn and in Winter.*

But if Cucumbers are required in perfection for the table as late in autumn as poſſible, it is proper to place ſome frames over a few holes of the beſt plants in Auguſt, and let them be ſhielded with the lights every night, and all cold wet weather; and thus, by preſerving the plants from cold and exceſſive moiſture, they will retain a healthful and moderately free growth till October or beginning of November, producing tolerably handſome fruit.

If the plants are growing on a dung-bed, formerly a hot-bed, I ſhould alſo adviſe, towards the middle or end of September, to line it on each ſide with hot dung, to throw in a little heat, which would be of much advantage; but even if the plants are growing in the full ground, it might be done by digging a trench at the back and front two feet wide, cutting it a little under, ſo filling it with hot dung, treading it in firmly, and as it ſettles continue adding more.

Or, to have late Cucumbers, ſome might be ſown in the natural ground, in a warm ſituation, the middle of July; place a frame over, and ſhelter them all along occaſionally with the lights; they will come into bearing the end of Auguſt, and, with due ſhelter, will continue longer than thoſe ſown a month or two before.

Or, if ſome ſeeds are ſown in the natural ground the end of July, or beginning of Auguſt, and tranſplanted with balls into a ſlender hot-bed under frames, about the latter end of the laſt-named month, they will come into bearing towards the latter end of September; and with proper ſhelter, and occaſionally lining the bed three or four weeks after making, they may be continued in bearing a few all October, and greateſt part of November.

And, if ſome ſeed is ſown in a ſlender hot-bed, or under glaſſes, the latter end of Auguſt, and tranſplanted into another of moderate ſtructure in the middle of September, they will arrive to a bearing ſtate in October, and, with care, will probably continue producing a few till December.

If ſome ſeed is ſown in September, as above, and tranſplanted into a hot-bed of tolerable ſubſtance, under frames and glaſſes, in October, managing them nearly as the early plants, you may ſtand a chance of having them produce now and then a fruit till Chriſtmas; and in this bed may alſo be ſown ſome ſeed in October and November, &c. to try to extend a crop of plants ſtill farther; there is, however, no great expectations to be formed from either of theſe crops, the declining ſeaſon of the year being unfavourable to their growth; and is, therefore, only worth practiſing in ſome family gardens, by way of curioſity, where a fruit or two at an uncommon ſeaſon may be greatly valued.

But by thus continuing to ſow ſome ſeed occaſionally, from early in ſpring till late in autumn, many have cut Cucumbers every month in the year.

It is, however, to be conſidered of all theſe autumn-raiſed crops of Cucumbers, that, by the nature of the ſeaſon, they, if ever ſo well managed, can never ſucceed ſo well as the ſpring and ſummer crops; but as a few fruit in October and November, after the general ſeaſon is paſt, may be eaſily obtained by the afore-mentioned rules, it will be eſteemed a rarity, and in moſt families highly acceptable.

*Saving the Seed.*

To ſave Cucumber-ſeed, ſome fruit either of the frame or hand-glaſs crops ſhould be left for that purpoſe; for thoſe of the late crops, in the natural ground, ſeldom ripen their ſeed perfectly.

Therefore, about May, or June, or July at lateſt, mark two or three of the fineſt fruit in each hole, and theſe ſituated near the main ſtem, that there may be the greater

chance of having the plants from that ſeed ſhew fruit near home, as the gardeners term it, meaning their beginning to ſhew fruit at the firſt, ſecond, or third joint, which is a principal merit in theſe plants, particularly the early crops.

But to inſure ſtill a greater chance of having early fruiting plants, I adviſe you to leave one or two of the earlieſt frame fruit, which appear at the above mentioned joints of the plant, and this will be choice ſeed for your early framing, as the plants will ſeldom fail ſhewing fruit at the beginning of their firſt runners.

Having, however, marked the fruit for ſeed in either of the above crops, they muſt be permitted to remain upon the plants till June, July, or Auguſt, according to the forward or late growth of the fruit; obſerving, thoſe which are produced and left for ſeed in March, April, or May, will be ripe in June and July; but thoſe produced in May or June will not be ripe till the middle of Auguſt, for the ſeeds ought to be perfectly well ripened.

When they are fully ripe, cut them from the plants, and ſet them up on end againſt a ſunny wall or hedge two or three weeks, or till their outer coat begins to decay; then cut them open, and turn out the ſeeds and pulp together into a tub or other veſſel, to remain a week or two, ſtirring it up every day, that the pulp may rot and ſeparate from the ſeeds; and then add ſome water, ſtirring the whole well about with a ſtick, the pulp will riſe like ſcum to the top, and the ſeeds will ſettle to the bottom of the tub; ſo that by a repetition of two or three waters the pulp will be ſeparated entirely from the ſeed, which ſhould then be ſpread upon a mat in the open air a few days, until perfectly dry, when it ſhould be put up in bags or boxes, and preſerved in a dry room for ſowing.

This ſeed will ſupport its growing quality eight or ten years, but is in the greateſt perfection in the third and fourth years, at which age they produce more fruitful plants than younger ſeed, which is apt to fly vigorouſly into vine, and ſhew fruit ſparingly.

*Second Head.*

CUCUMIS MELO, the Melon, or Muſk-Melon, *(Melo)*.

The Melon, as we before obſerved, is, according to the Linnæan ſyſtem, a ſpecies of *Cucumis*, and conſiderably the moſt valuable ſpecies of that genus, in reſpect to the excellence of its fruit, which, for deliciouſneſs of flavour and taſte, is next in eſtimation to the pine-apple, the fleſh or pulp being both pleaſant and grateful to the ſtomach, and its ſmell and taſte indicate it of an aromatic quality.

Claſs, order, and characters, the ſame as the *Cucumis*.

Of the Melon, there is but one real ſpecies of the plant, but of the fruit there are innumerable varieties, with reſpect to figure, ſize, colour of the rind, and fleſh or pulp.

The ſpecies is,

CUCUMIS *Melo*.

*The Melon.*] Cucumis with roots compoſed of numerous, very ſmall, widely ſpreading fibres; long trailing ſtalks, divided into many branches, ſpreading on the ground, furniſhed with tendrils; roundiſh, angular, rough leaves; ſmalliſh, bell-ſhaped, yellow male and female flowers, the females ſucceeded by a large, oval, and ſometimes roundiſh fruit, often channelled, or ribbed longitudinally, having a firm muſk-ſcented fleſh, and many oblong ſeeds included in a watery pulp.

This fruit, in different varieties, is of various ſizes, from about four to ten or twelve inches in length and diameter, in moſt ſorts ripening externally to a yellowiſh colour, and ſome ripen green, and others white, but have moſtly a reddiſh fleſh or pulp, except one variety, which is green both in rind and pulp, as hereafter deſcribed.

The varieties of moſt eſtimation at preſent in the Engliſh gardens are,

*Common Muſk-Melon*——A large, oblong-oval, longitudinally-ribbed, and netted-wrought Melon, having a reddiſh tolerably rich flavoured fleſh; and the plants being of the hardier kind, generally ſet a plentiful crop of fruit.—This is alſo one of the beſt ſorts of Melon for mangoes, and for which purpoſe the London gardeners cultivate principally this variety for the ſupply of markets.

*Romana Melon*——A roundiſh, moderate-ſized, ribbed, and netted Melon, ſomewhat compreſſed at both ends, and with a reddiſh firm fleſh of a fine rich flavour, the plants good bearers, each often ſetting from about five or ſix to eight or ten fruit, and is one of the beſt ſorts, both for an early and general crop.

*Cantaleupe, or Armenian Warted Melon*—A large, roundiſh, deeply-ribbed Melon, a little compreſſed at both ends, and the ſurface full,

full of warted protuberances, and with a reddiſh firm fleſh of a moſt delicious rich flavour, of which there are ſome varieties—Large Black Carbuncled or Black-rock Cantaleupe Melon, being of a blackiſh green colour, having the ſurface covered with high, rugged, ſaxtile protuberances——Large White Carbuncled Cantaleupe Melon—Orange Cantaleupe Melon —Theſe varieties are the fineſt of the Melon kind, with reſpect to the richneſs of flavour of the fruit, and which by the Melon-eaters are preferred to all the other ſorts; but the plants being rather more tender, do not ſet fruit ſo freely, nor in ſuch plenty, they often not having more than from one to two or three fruit on a plant, and that in a three-light frame ſometimes not more than five or ſix fruit, and frequently not ſo many; as the fruit, however, obtains the higheſt eſtimation, the ſeveral varieties of this ſort are now generally valued for the principal crop in family gardens; obſerving, that, to preſerve theſe varieties diſtinct, they ſhould not be cultivated in the ſame frame with other ſorts, nor with each other, for the commixture of farina would occaſion a degeneracy; alſo by ſaving the ſeed long in the ſame garden, the fruit often gradually loſes its ſaxtile or rock diſpoſition, and the ſurface becomes quite plane, bearing great reſemblance to the Romana Melon.

This variety derives the term Cantaleupe Melon, from Cantaleupe near Rome, the place where it was firſt cultivated in Europe, brought thence from Armenia.

*Small Portugal Melon*—A ſmalliſh round Melon, having a reddiſh fleſh of a fine muſky flavour, and the plants are plentiful bearers, each often ſetting from eight or ten to twenty fruit, which, however, is more by half than ſhould be left to come to perfection.

*Green-fleſhed Melon*—An oval, moderate-ſized Melon, having an even, ſmooth, green rind, and the fleſh or pulp ripening to a greeniſh colour, which is highly flavoured.

*Large Green-rinded Melon*—A large roundiſh-oval, green, ſmooth-rinded Melon, having a reddiſh fleſh.

*Black Galloway Melon*—A roundiſh oval, middle-ſized, ſlightly-ribbed, dark-green, ſmooth Melon, having a reddiſh, rich-flavoured fleſh, and the plants excellent bearers, but the ſort not at preſent very plentiful in England.

It was brought from Portugal many years ſince by a lord Galloway.

*Netted or Wrought Melon*—An oval, middle-ſized, ſcarcely ribbed Melon, having the ſurface cloſely wrought with raiſed net-work, and hath a reddiſh fleſh.

*White Spaniſh Melon*—An oval, ſmalliſh, white, ſmooth-rinded Melon, having a reddiſh pulp.

*Zatta Melon*—A very ſmall, roundiſh, warty-rinded Melon.

Obſerve, that although all the above kinds be only varieties of the ſame ſpecies, yet, by care in cultivating them ſeparate, they may be continued all tolerably permanent.

There are many other intermediate varieties of leſs note, but a few of known good qualities is better than many different ſorts, ſome of which probably not much better than gourds; and of the varieties here ſpecified, the *Romana* and *Cantaleupe* kinds are conſiderably the moſt worthy of attention, as theſe two ſorts ripen to a much higher degree of perfection; but the other varieties alſo ripen perfectly here, and often of a rich and good flavour, though at all times inferior to the two above mentioned ſorts, more particularly the true Cantaleupe kind; however, where there are great quantities wanted, and all proper conveniencies, I ſhould adviſe, for the ſake of variety, to cultivate ſome of each ſort; but to give preference to the Romana and Cantaleupe for general crops.

The Melon plant is an herbaceous annual, and one of the moſt ſingular and wonderful of that tribe, if we conſider its ſlender and proſtrate growth, trailing upon the ſurface of the earth, and being but of ſix or eight months duration, yet produces fruit of ſuch admirable figure, ſize, and richneſs of taſte.

It is an exotic from the hot parts of the world, ſuppoſed principally of Perſia, from which country, however, it was firſt introduced into the different parts of Europe; and conſequently its culture in every part of Britain can be effected only by artificial heat, and conſtant ſhelter of glaſs, &c. till July, as at an early ſeaſon they require a temperature of heat almoſt equal to that of our pine-apple ſtoves.

The principal ſeaſon of ripe Melons in England, is June, July, and Auguſt; they, however, by different ſowings and plantings, may be obtained from May till October; but they are always in the greateſt perfection in the times before mentioned.

The flowers of the Melon are conſequently *monoecious*, like the Cucumber, as being of the ſame genus and claſs, male and female apart on the ſame plant, the males ſtanding immediately

immediately on the ſummit of its foot-ſtalk, without any appearance of germen or fruit under it, and the females diſcover the round germen or embrio fruit under its baſe, when not bigger than a pea; obſerving, that the male bloſſoms are by nature deſigned for fertilizing the female flower, as obſerved of the Cucumber, ſo muſt not be pulled off until a full crop of fruit is ſet.

*Obſervations on their General Culture.*

With regard to the propagation of the Melon, the plants being annual, are raiſed every year from ſeed, ſowed at different times in ſpring, in hot-beds of dung or tanner's bark, under frames and glaſſes, &c. they requiring continual aid of artificial heat and ſhelter, from the time of ſowing until June or July, for they will at no time ſucceed in the natural ground, at leaſt rarely perfect fruit; and each crop requires two different hot-beds, that is, to be ſowed in one, and the plants nurſed therein till a month or ſix weeks old, that they begin to ſhoot runners, then tranſplanted into a ſecond and final hot-bed, to remain to fruit.

The ſeaſon for ſowing is any time from the beginning of January until the middle of April, according to the conveniencies there may be for their culture, and time the fruit is required in perfection; for the early crops to be raiſed in January, February, and beginning of March, require very ſubſtantial hot-beds, under conſtant ſhelter of garden-frames and lights, until July; but the later crops, ſown in the middle of March and in April, ſucceed with more moderate hot-beds, and may be ridged out in April and May under hand or bell glaſſes, or oiled paper frames, and the plants will ſet and ripen their fruit under theſe ſhelters; obſerving, that the early ſowings in January ſometimes produce ripe fruit in May, but come into full bearing in June; and thoſe raiſed in February, and early in March, ripen fruit in June, July, and Auguſt; and ſowings performed any time from about the middle of March till that of April, furniſh ripe fruit principally in Auguſt and September, and ſometimes in October.

Obſerve, therefore, that, like the Cucumbers, crops of Melons may be raiſed in three different ways; under frames and lights, under hand or bell glaſſes, and under oiled paper; each of which ſhall be exhibited under a ſeparate head.

The materials principally neceſſary in their culture are,

Frames and glaſs lights for early, and hand-glaſſes, &c. and oiled paper lights, for late crops; and for each crop good mats for covering on nights; all as obſerved for the Cucumbers.

Horſe ſtable dung, a plentiful ſupply both for making the hot-beds, and for occaſional linings, which muſt be in quality, quantity, and preparation, as hinted for Cucumbers, and in the article HOT-BEDS.

But ſometimes in the Melon culture bark hot-beds are employed, or of bark and dung together, which, where tanner's-bark can be eaſily procured, on account of its regular and durable heat, is a very proper material for hot-beds in the culture of Melons, either uſed alone, or mixed with hot dung, as explained in its proper place.

As to mould, the Melon, like the Cucumber, will proſper in any rich pliable kitchen-garden earth, prepared ſome months in a heap; but the favourite and moſt proſperous ſoil for the Melon is a fine mellow loam, taken from the ſurface of a paſture field or common, enriching it with about one-third of rotten neat's dung, or thoroughly rotten dung of old hot-beds, preparing the whole in a heap, and managed as directed under the article COMPOSTS; obſerving, that when it is to be uſed, not to ſift or ſcreen any, only break it well to pieces with the ſpade.

The ſituation, or place for making the hot-beds, ſhould be dry, warm, full the to ſun, and ſheltered, as for Cucumbers; likewiſe obſerve, not to dig any trench for the early hot-beds, but make them entirely on the ſurface of the ground, for the reaſons there aſſigned.

It is generally adviſed to cultivate Melons as far as poſſible diſtant from Cucumbers, leſt, by an intercommunication of their *farina*, it ſhould cauſe a degeneracy; there is apparently ſome reaſon in this: however, when we conſider that the two plants are real different ſpecies, I believe there is no great danger to be apprehended, as in the caſe of varieties.

The ſeed, and its kind, being material articles, you ſhould be particularly careful to procure ſuch only which have been ſaved from the very fineſt fruit of the reſpective approved varieties; this, if poſſible, ſhould be two or three years old, for the reaſons obſerved of the Cucumber ſeed; but when you are obliged to uſe new ſeed, it is proper either to hang them in a paper, or phial, in a dry room

room near the fire, all winter, or in a phial, expoſed in a dry window to the ſun; or may carry them in your pockets three or four weeks, either of which expedients will dry up much of the watery parts, whereby the plants will be leſs luxuriant and more fruitful. We receive Melon ſeeds annually from France, Spain, Italy, and other hot countries; but I would caution againſt depending on theſe for a principal crop, for not being inured to this climate, the plants from ſuch would be more tender and delicate in their culture, leſs fruitful, and the fruit often of much leſs value, than thoſe of ſeeds ſaved at home; therefore, only a plant or two of theſe foreign ſeeds ſhould be raiſed at firſt, juſt to prove the quality of the fruit.

From the time of ſowing the ſeed to the maturity of the fruit, it is commonly near four months, and ſometimes longer; for the plants ſeldom ſhew fruit till they have ſhot ſeveral runners, which, from the firſt appearance of the plants, will be at leaſt ſix or eight weeks in effecting; from the appearance of the fruit till it is fairly ſet, a week or fortnight; and from its ſetting till fully ripe will be about forty days.

The proper quantity of hot-bed in the culture of Melons for private uſe is, that for the ſmalleſt family there cannot be leſs than one three-light frame for the early, and three hand or bell-glaſſes, or three holes under oiled paper, for the late or ſucceſſion crops, allowing two plants to each light of the frame, the ſame to each hand-glaſs, or hole under the paper lights; and ſuppoſing each plant, one with another, to produce about three fruit, ſo that in a three light frame, and in three holes under hand glaſſes, or oiled paper ſhelters, there will be but about from thirty to forty Melons; though of the ſmaller ſorts of Melon there will ſometimes be from ſix to ten, or twelve, or more, on a plant; but ſix or eight is as many as the plants are able to bring to perfection: however, for the ſupply of a middling family, two three light frames, and, at leaſt, ſix hand or bell-glaſſes, &c. will be neceſſary to furniſh a tolerable ſupply during the ſeaſon; and for a large family, four three-light frames, at leaſt, or twelve lights, will be requiſite, and double that number of hand-glaſſes, or holes of plants under paper frames.

We now proceed to the different methods of culture; and firſt of their early culture in frames, obſerve as follows.

*Their Early Culture in Frames by Dung Hot-beds.*

The time of year to begin the culture of Melons in frames, is January, February, and beginning of March; but when deſigned to have Melons as early as poſſible, we commonly begin in January, though the beginning of February is a more ſucceſsful time of ſowing to have a good crop; if, however, you begin early in January, it is proper to ſow alſo twice in February and March for ſucceſſion crops; likewiſe to be ready in caſe of accidents to the early plants, or that they ſhould not thrive, as is often the caſe at a very early ſeaſon.

The ſeed may be ſowed, and the plants raiſed, either in a hot-bed of early Cucumbers now at work, in the ſame manner in every reſpect as for them directed; or, where none is, make a hot-bed for a one-light frame on purpoſe, obſerving exactly the ſame rules with reſpect to dimenſions, making, framing, and earthing the bed, ſowing the ſeed, and other management, as directed for the early Cucumbers; likewiſe, when the plants have been come up three days, that their cotyledons are a little expanded, tranſplant or prick them into ſmall pots for the convenience of removal, as there directed; but of theſe, i. e. Melons, put only two plants in each pot, plunging them in the bed, and manage them as above till fit to ridge out; for the Cucumbers and Melons, being nearly of equal temperature, the ſame degree of heat, air, &c. ſuits both in this part of their culture; it would therefore be ſuperfluous to trouble the reader with a repetition, ſince the particulars are fully exhibited under the article of *The Early Culture of Cucumbers in Frames.*

In this nurſery-bed they are to be continued a month or ſix weeks, till their firſt runners begin to advance; obſerving, as their ſhanks riſe in height, to earth them up by degrees with fine mould, till the pots are full, for this will greatly encourage them, and they will come faſt into the rough leaf, and begin to form joints and ſhoot runners.

Obſerve, when their two or three firſt rough leaves are fully expanded, and another forming in the centre, appearing like a bud, which part being alſo the end of an advancing ſhoot, it ſhould juſt at this period of its growth be ſtopped, i. e. cut or pinched off cloſe to the ſecond or third leaf, as adviſed for the Cucumbers, to procure lateral ſhoots, called runners; for it is from theſe, or others iſſuing from them, that we are to expect the

fruit;

fruit; and when theſe firſt runners appear, the plants are ready for ridging out into the fruiting hot-bed.

The plants from the time of ſowing, till arrived at the above ſize for ridging-out, take about five or ſix weeks growth.

The ridging-out, or fruiting hot-bed, ſhould be prepared in due time to receive the plants when arrived to the proper age and ſize above mentioned; obſerving, to prepare freſh hot dung a week or two in a heap, as for the Cucumbers, ſufficient for one or more three-light frames; let the bed be made entirely on the ſurface, for the opportunity of lining, carrying it up three feet and half, or four feet high, raiſing the back or north ſide three or four inches higher; directly put on the frame and lights, to defend the bed from chilling rains, and to draw up the heat, tilting the glaſſes behind for the ſteam to paſs away; and in a week, or ten or fifteen days, according to the ſubſtance of the bed, its firſt great heat will abate; then prepare to mould it, and put in the plants, obſerving the neceſſary precautions, as for the Cucumber beds.

The bed being ready, as above, then wheel in your prepared mould, and lay juſt under the middle of each light about a buſhel of it in a heap, for the immediate reception of the plants, forming each heap into a ſort of conical hillock about fifteen inches high; and by thus having the hills of earth this height, is proper both that the plants may be near the glaſſes, which is of importance in early work, and to allow them a good depth of earth; for they ſhould generally have a greater depth of mould than Cucumbers, the plants being more impatient of moiſture by watering, which is alſo prejudicial to the proſperity and flavour of the fruit, that, therefore, by allowing a good depth of earth, they will ſhift much longer without the aid of water: when the hillocks are thus formed, directly earth the other parts of the bed within the frame three inches thick, juſt to keep down the ſteam riſing immediately from the dung; then ſhut down the lights, and when the earth is warm put in the plants.

In a day or two the heat of the dung will have ſufficiently warmed the hills of earth; then bring the plants in their pots; being two in each, plant one pot of plants, with the balls of earth about their roots, in the middle of each hill, as directed for the Cucumbers; and if the mould ſhould appear dry, give a little water towards the outſide, being careful not to wet the plants much at this time; and as ſoon as planted ſhut down the lights, to draw up the heat about the roots of the plants, but tilt them again in due time, to paſs off the ſteam.

The plants being now ridged out into the fruiting hot-bed, obſerve, that as the glaſſes are to be continued conſtantly on the frames till July, your daily care is to admit freſh air at all opportunities in calm weather, by tilting the lights behind from about half an inch to two, three, or four high, according to the temperature of the heat and ſteam of the bed, and that of the outward air, which muſt be alſo obſerved occaſionally on nights at firſt ridging-out, if there is a great ſteam, for this muſt not be pent up, nor ſtagnated for want of air; cover the glaſſes alſo every night with mats, one or two thick, as ſhall ſeem neceſſary, but never let them hang down all over the ſides of the frame and bed, as often done, which would draw up a violent ſteam, and exclude the air too much from the plants, and draw them up weak and of a yellow colour; give water alſo occaſionally when the earth appears dry: obſerving, that in the performance of all of the above works in this bed, to follow ſtrictly the ſame rules as exhibited in the ridging-out bed of early Cucumbers; but to keep in mind, that Melons being rather impatient of moiſture, muſt have it more ſeldom, and leſs in proportion, than for Cucumbers, eſpecially near the main ſtem and principal roots; for by much moiſture theſe parts are apt to canker and rot, ſo ſhould be watered moſtly at ſome diſtance from theſe principal parts, and never to wet the vine much at an early ſeaſon; but when there is not leſs than twelve or fifteen inches depth of earth on the beds, they will not need water oftener than once a fortnight; and ſometimes, when the earth is of a loamy nature and depth as above, and preſſed down cloſe, that it may the better retain its natural moiſtneſs, the plants, after two or three waterings, till they have firmly eſtabliſhed their roots, will often ſucceed without, or, at leaſt, with very little more water; and in which caſe they generally ſet their fruit freely, and it ripens to a rich and high flavour, for redundancy of moiſture retards the ſetting of the fruit; and although, after it is fairly ſet, occaſional waterings will encreaſe its magnitude, yet much of it greatly debaſes its flavour and taſte; but on the other hand obſerve, that where the earth of the beds is of a light

texture,

texture, or of but a moderate depth, the plants will all along require occaſional waterings, eſpecially in warm ſunny weather; let it however be remembered, that when the plants exhibit their firſt ſhew of young fruit, no water, or as little as poſſible, ſhould be given, until the fruit is ſet as big as large walnuts, when, agreeable to the nature and proportion of earth, and other rules as above mentioned, and as hereafter hinted, uſe your diſcretion accordingly in watering.

Examine with care for the firſt week after ridging out, that the earth of the hills and roots of the plants do not receive too much heat from the violence of the bed; and if there is danger, remove ſome of the earth around the lower part of each hill; and if any is burned at bottom, add directly ſome freſh in its ſtead, and in a few days or a week the burning quality will ſubſide; then replace the removed mould again about the hillocks.

After danger of burning is paſt, cheriſh the heat as much as poſſible, by laying dry long litter around the ſides of the bed, to defend it from chilling wet and cold piercing winds.

When the heat begins to decline conſiderably, be ſure to revive it as ſoon as poſſible, by adding a ſubſtantial lining of hot dung to the ſides of the bed at different times, as practiſed to the Cucumber beds, uſing the ſame precaution of earthing the top, &c. to prevent the ſteam of the linings entering under the bottom, or at any part of the frame; for the rancid ſteam coming directly from the dung would deſtroy the plants.

When the fibres of the plants begin to advance through the hills of earth, let ſome freſh mould be layed in the frame at different times to warm, and by degrees add each parcel around the hills, till the whole bed is gradually moulded nearly as high as the top of them; but rather let the top of each hill be about an inch higher, that the main ſtem and principal roots may be preſerved moderately dry, otherwiſe, being watered, would ſoak to theſe principal parts, and cauſe them to rot, as being very impatient of copious moiſture from watering, &c. therefore, according as the mould is occaſionally added, obſerve the afore-mentioned precaution; alſo to preſs it down cloſe, that by lying compact it may retain a due moiſture in itſelf the longer, ſo as the plants will require to be but ſeldom watered.

As the runners of the plants advance, diſpoſe them with regularity, and when they are three joints long, if no young fruit appears, it is proper to perform a ſecond ſtopping, by taking off the end of the extreme joint, to promote a more ſpeedy ſupply of other lateral runners, which, together with others, naturally ariſing from them, will ſufficiently ſpread the bed with vine; and it is from theſe lateral ſhoots we may generally expect ſoon to ſee plenty of young fruit.

At the firſt training the vines, as above, if ſome dry and clean reeds are thinly ſpread upon the ſurface of the bed for the vines to run upon, it will preſerve all the runners and young fruit from the damp of the earth, as well as prevent the earth and upper fibres of the roots from being dried too faſt by the ſun; ſome, for the above purpoſes, cover the bed all over cloſely with plane tiles; but this I ſhould think rather excludes the neceſſary benefit of ſun and air, too much from the earth and roots of the plants.

When the young fruit begins to appear, it is of much importance to ſupport a due temperature of heat in the beds, by occaſional linings, &c. do not omit this, becauſe the whole ſucceſs of having the plants ſet a regular and a plentiful crop of fruit depends on a good bottom heat, both to warm the earth ſufficiently about the fibres, as well as the internal air of the frame; for theſe fruit being ſo extremely tender whilſt young, that without a proper heat they ſet very ſparing and ſtragglingly, generally aſſuming a ſlow, ſtunted, and irregular habit of growth; maintain, therefore, the neceſſary degree of heat, and the fruit will ſet freely, and ſwell faſt in magnitude.

At this period alſo of the firſt appearance of the fruit, I ſhould adviſe to forbear watering, if poſſible, till the fruit is ſet as large as good walnuts, as we above obſerved; obſerving, that if the plants are growing in a tolerable depth of ſoil of a loamy nature, they will ſhift very well without any during that period, or longer, unleſs the earth ſhould be very dry indeed, and then let them have it but ſparingly; for if any conſiderable portion of water is given when the fruit is ſetting, the vine will acquire a glut of ſap, and continue ſhooting with great luxuriancy, which is contrary to the nature of theſe young fruit, as, being of ſuch a delicate temperature in their infant ſtate, and even during their minor growth, that the exuberant quantity of ſap in the branches cauſes them to turn yellow, and drop off ſoon after they have bloſſomed,

and ſometimes after they have ſet as large as an egg, and more eſpecially if there is not a due degree of warmth in the beds.

According as the young fruit appears, you will obſerve it accompanied by abundance of male bloſſoms; theſe muſt not be picked off, as too often practiſed, their *pulvis antherarum*, or powder of their antheræ, being abſolutely neceſſary for fecundating the female flowers, and fertilizing the young fruit; it is therefore of importance, not only to retain theſe flowers, but that to aſſiſt nature, it is proper, in the early crops, to perform the operation of ſetting, i. e. of applying their antheræ to the ſtigmata of the female bloſſoms, as directed for the Cucumbers, uſing for this purpoſe ſuch male flowers whoſe antheræ are duly ripened, and well furniſhed with *farina*, which you may readily know by previouſly applying the antheræ gently to the thumb nail, to which ſome of the *pollen*, if ripened, will adhere; ſo uſing one or two males to each female bloſſom, and it will be found to aſſiſt greatly in ſetting the early fruit.

Air, at this time of bloſſoming, will alſo be particularly beneficial in promoting the free ſetting of the fruit; do not omit therefore to admit it every mild day, according to the rules formerly mentioned.

After ſetting the fruit obſerve, that as they are moſt commonly produced on the lateral runners, iſſuing from the ſides of the main vine, and that exuberancy of ſap retards their ſetting, I would adviſe, if your plants are rather luxuriant, that, to reſtrain the ſap from flowing too abundantly into the ſetting fruit, inſtead of ſtopping the end of the runner, as often done, rather turn it carefully curve-ways, ſo that the end may incline towards the main ſtem, whereby the ſap will be directed from the bearing runners, and its courſe continued principally into the more luxuriant branches; and the ſooner this is done the better, which, after the fruit is ſet, and a little advanced in growth, muſt be turned again into their former poſition. Many perſons prune off the ends of the bearing runners a joint or two beyond the fruit, in order that the whole nouriſhment of that branch ſhould be directed to it, to make it more certainly ſtand; but this has often the contrary effect, ſince ſtopping or ſhortening a branch promotes its drawing a greater quantity of ſap, which, as we above obſerved, is contrary to ſetting theſe fruit; therefore, thoſe branches on which the ſetting fruit are immediately ſituated, ſhould not be ſtopped until the fruit is fairly ſet, and full as big as a large walnut.

Neither is it proper to ſtop many of the runners, which would occaſion their throwing out numerous ſhoots, and cauſe a great confuſion of vine.

As the fruit ſets, and has attained nearly the ſize juſt mentioned, the branches on which they grow, if they were turned towards the main ſtem, as above adviſed, ſhould now be reconducted into their former directions, that the ſap may now find a freer paſſage to nouriſh the fruit.

Likewiſe, as the fruit ſets, lay a piece of clean dry tile under each, to preſerve it the better from the moiſture of the earth.

The quantity of fruit to be expected to ſet and arrive to perfection, is from about two or three, to eight or ten upon each plant; but this is according to the ſorts, for the Cantelupe Melon ſometimes does not ſet above two or three on a plant; on the other hand, the Romana will ſometimes ſet and ripen eight or ten, and ſometimes many more fruit will ſet than the plants are capable of nouriſhing; but, when this is the caſe, they ſhould be thinned; and even of the ſmaller kinds leave only about ſix or eight of the moſt promiſing fruit upon each plant, and not more than five or ſix of the larger kinds, and never leave more than one fruit upon the ſame runner, and that which is neareſt the main vine is generally the moſt eligible to leave, though it is beſt to fix upon that of the forwardeſt and handſomeſt growth.

After a tolerable crop of fruit is ſet, and they advanced in magnitude, if the earth of the bed is dry, take the firſt opportunity of a mild day to give a good watering, eſpecially if the bed is kept to a proper heat, which, according to the nature of the earth, and its depth on the beds, may be afterwards either wholly diſcontinued, or leſs or more repeated, as you ſhall ſee occaſion by the temperature of moiſtneſs, or dryneſs of the earth; obſerving, in giving water, let it be rather moſt towards the ſides of the bed, ſo as ſtill to preſerve the main ſtem and principal root always moderately dry.

Continue alſo admitting air at all opportunities every day when the weather is fine, which is alſo very beneficial to the free growth of the young ſwelling fruit.

Still, likewiſe, continue to ſupport a due temperature of heat in the bed by occaſional linings with the uſual care, even till

May;

May; for, by maintaining a bottom heat, the fruit will ſwell freely, continue a regular growth, and be in a little time ſurpriſingly forwarded in magnitude. In applying the laſt lining in April, or beginning or middle of May, it is proper to earth it at top equal in depth to that of the bed, as obſerved of the Cucumber, and by raiſing the frame the fibres of the plants will ſtrike into the mould, and receive very great benefit, as will be evident from the healthful appearance of the plants, and free growth of the fruit; but obſerving, this part ſhould be defended from great rains with mats, that the extreme fibres may not receive and convey too much moiſture to the vines and fruit, otherwiſe it would be more adviſeable to confine the fibres wholly within the frame.

Shading the plants occaſionally from the ſun may be neceſſary in very hot days, when the ſun is ſo powerful as to endanger ſcorching their leaves, &c. obſerving the ſame rules as for the early Cucumbers.

As the leaves of the plants grow large, and preſs againſt the glaſſes, continue to raiſe the frame at bottom three inches; and as, in doing this, the earth next the frame will be diſturbed, directly therefore make good all inequalities; and, if the leaves are conſiderably crouded, it is proper to thin them a little in proportion, ſo as that the young fruit may receive the neceſſary benefit of the ſun and air.

If, after a due quantity of fruit is fairly ſet, and advancing in growth, the vine is greatly crouded, it is proper to regulate them, by cutting off cloſe all ſmall runners, proceeding from the principal fruit-branches, and others, and any luxuriant ſhoots that ſupport neither bearing runners nor fruit, and ſuch other vine as your obſervation ſhall judge to be ſuperfluous or unneceſſary, cutting them off quite cloſe, which will greatly encourage the free growth, and promote the ſize of the Melons.

In May and June, as the vines of the plants will be advanced to the ſides of the frame, if you have a full crop of fruit fairly ſet, they may be pruned ſo as to confine them within due compaſs; or, if you would have as many fruit as poſſible to ſucceed each other, they may be ſuffered to run out from under the frame upon the top of the lining, to produce ſome late fruit to ſucceed thoſe already ſet within the frame, raiſing the frame high enough at bottom for that purpoſe towards the middle of June; obſerving, when the vines are thus trained out, to cover them every night, and all very wet weather, with mats; for the glaſſes muſt alſo ſtill be continued on the frames till the weather is become quite ſettled and warm towards the end of this, or in next month (July), and then only taken off a few hours in the warmeſt time of the day, and always put on at night and all wet weather.

When the fruit is nearly full grown, no water, or at leaſt very little ſhould be given; for moiſture will conſiderably retard its ripening, as well as rob it of the richneſs of its flavour. At this period of growth let each fruit be placed upon a brick, or ſome flat tiles, placed one upon another, to raiſe it a little above the leaves, to receive the greater benefit of the ſun and air, whereby its flavour and reliſh will be conſiderably improved, being careful to turn it every three days, that every part may equally enjoy the benefit of the ſun's influence; obſerving alſo, at this time, to admit a large portion of freſh air every mild day, by tilting the lights ſeveral inches behind, or in front, in very hot weather, which will alſo contribute very much to the rich flavour of the ripening fruit.

From the ſetting of the fruit to its maturity, it takes commonly about ſix or ſeven weeks, and ſometimes more.

The maturity of the fruit is known ſometimes by its cracking at the baſe, as if it would ſtart or recede from the ſtalk; ſometimes by its inclining to a yellow colour; frequently by imparting a fragrant odour; and when the top of the fruit is ſoft, it is always a ſure indication of ripeneſs; therefore, obſerving theſe appearances of maturity, let the fruit be cut at the proper time; for if ſuffered to remain on the vine a day or two longer, it will looſe much of its flavour. Let it be cut in a morning before the ſun ſhines hot to evaporate its rich juices, cutting each fruit with all its ſtalk, and lay it in a dry but cool airy place till it is wanted for table.

In the latter end of June, and in July, if the weather is dry and warm, the plants may be gradually inured to the full air, by ſhoving the glaſſes off a few hours in fine dry days; but let them not have much rain, leſt it rot the main ſtem of the plants, and it would alſo debaſe the flavour of the fruit; therefore retain the glaſſes ready at the back of the frames, to draw on every night, and all very wet and boiſterous weather.

*Their Culture under Hand or Bell-glaſſes.*

Principal crops of Melons, to ſucceed the forward crops in frames, are moſt commonly obtained by ridging out plants in hot-beds, under hand or bell-glaſſes, in April or May, for they will then, and not before, ſucceed by this mode of culture; therefore, that for the main crop to come in after Midſummer, you may ſave the expence of frames, as obſerved of the Cucumbers; or if the frames are all employed, or that you are not ſufficiently provided with ſuch conveniencies, you may always have a good crop of Melons under theſe kind of glaſſes, ripening in July, Auguſt, and September.

The culture of Melons under theſe hand or bell-glaſſes is effected by ſowing the ſeed in March or April, in a nurſery hot-bed, under frames and lights, and when the plants are about a month old tranſplant them into ridges or hot-beds, under the above glaſſes, to remain for fruiting; but, in default of frames, the plants might even be raiſed entirely under hand or bell-glaſſes, placed on a hot-bed, ſowing them in April, and tranſplant them into a freſh hot-bed in May, under the ſame ſort of glaſſes, or oiled paper lights; they will ſometimes come in for a tolerable crop in Auguſt and September; however, the moſt eligible practice is, where poſſible, to ſow and forward the plants in a hot-bed, under frames, pricking the young plants in pots, ſo continuing them in the frame hot-bed till large enough to ridge out, then tranſplant them with balls into the fruiting hot-bed.

The moſt proper period of time for ſowing the above crops is, the third and fourth week in March; but, if poſſible, for the main crops, never be later than the firſt week in April.

And the time for ridging-out the plants under theſe glaſſes, is from about the eighteenth or twentieth of April until about the middle of May.

For, it muſt be remembered, that the plants for theſe hand-glaſs crops muſt never be raiſed nor ridged out before the above-mentioned times, otherwiſe they would advance too forward in growth, and fill the glaſſes before the nature of the ſeaſon admitted of their being trained out, unleſs ſheltered by paper frames, as they muſt not be confined within the ſmall compaſs of theſe glaſſes, longer than the beginning or middle of June, that the weather becomes ſettled and warm; nor ought the principal crops to be ſowed nor ridged out later than the times above ſpecified, becauſe they would not be forward enough to ripen their fruit in perfection before the approach of cold weather in autumn.

The ſeed may be ſown, and the plants raiſed large enough for ridging out, either in the hot beds of forward Melons or Cucumbers now at work under frames, or in a ſmall hot-bed made on purpoſe for a one-light box, &c. earthed a few inches deep, ſowing the ſeed either in pots half an inch deep, or in the earth of the bed, drilling it in that depth, ſo managing the ſame as for the ſeedling Melons and Cucumbers for the frames; prick the plants alſo in pots, when a few days old two in each pot, as in the frame crops, giving them nearly the ſame culture; and having expanded their two firſt rough leaves, ſtop them at the firſt joint, as there directed; and when a month or five weeks old they will begin to ſhoot runners, and ſhould then be ridged out into the fruiting hot-bed.

Therefore you muſt forecaſt to prepare the dung, and make the ridges or hot-beds in proper time, to be ready to receive the plants at the above period of growth.

The dimenſions of the fruiting hot-bed ſhould be four feet and half wide, and, if made in April, two feet and half, or a yard high; and even if made early in May, two feet and half depth of dung will be requiſite; nor ſhould it be leſs than two feet high, made in any time of that month; and the length in proportion to the number of glaſſes you intend working, allowing them at a yard and half diſtance from centre to centre, in one row along the top of the bed; obſerving, that if the plants are ready for ridging out in April, or beginning of May, I would make the bed entirely above ground, for the opportunity of lining the ſides when the heat declines; or, at this ſeaſon, if the ground be tolerably dry, ſo as there will not be much danger of water ſtanding, the bed may be made in a trench, for the advantage of having it retain its heat the longer, making the trench four feet and half wide, and eighteen or twenty inches deep; but obſerving, that in three weeks after the bed is made, the trench muſt be widened a foot and half on each ſide, and to the full depth to admit of a lining of dung that width and depth to each ſide of the bed; for hot-beds made for theſe plants at either of the above mentioned times, either on level ground or in a trench, will receive

receive conſiderable benefit by having a lining of hot dung added to each ſide in three or four weeks after making, which will not only throw in a freſh heat, but, by being earthed at top, gives an additional width for the roots and vines of the plants to extend; obſerve likewiſe, that if more than one range of hot beds are intended, make them one before another in a parallel direction, allowing a ſpace of four or five feet between, which, if afterwards entirely filled up as high as the ridge with hot dung and earth will be of great advantage to the plants.

The ridge or ridges being made, then, according to the rules and precautions exhibited in the hand-glaſs crop of Cucumbers, prepare to earth it with the proper compoſt for the reception of the plants, firſt marking out with ſticks the places for the glaſſes, in a row along the top of the bed, at a yard and half diſtance; and then, on each place where the glaſſes are to ſtand, lay about a wheel-barrow full of mould in a hill fifteen inches high at leaſt, and wide enough for a hand-glaſs, for this depth of earth is as neceſſary here as in the frame crops, covering the other parts of the bed between the hills only three inches deep at preſent, that the burning ſteam and heat may have due vent, yet to prevent it from evaporating too ſuddenly, but is afterwards to be gradually earthed almoſt as high as the top of each hillock: as ſoon as the bed is thus earthed ſet on the glaſſes, one upon each hill of earth, covering the whole with mats at night, to draw up the heat the ſooner, and in a day or two the earth will be warm enough to receive the plants.

When the earth, therefore, under the glaſſes is properly warmed by the dung, then, having previouſly watered the pots of plants the day before, that the earth may adhere in a ball about their roots, proceed to plant one pot of two plants under each glaſs, removing the plants out of the pots with a ball, in the manner directed in the early Cucumber hotbeds; and levelling the tops of the hillocks broad enough for each glaſs to ſtand; make a wide hole in the middle, and plant the ball of plants, giving directly a moderate watering, and put on the glaſſes, which muſt remain conſtantly over the plants, and be covered every night for a month or two, and all bad weather, with mats.

They being now ridged out, obſerve, if their removal cauſes them to flag their leaves at the approach of the ſun, it is neceſſary to indulge them with a moderate ſhade the firſt three or four days, when ſunny, or till they ſtand the ſun fully without flagging.

Freſh air muſt alſo be occaſionally admitted in the warmeſt time of every fine day, by tilting the warm ſide of the glaſſes an inch, or a little more or leſs, according to the heat of the bed and temperature of the weather, having particular attention to ſhut them down cloſe in due time in the afternoon, or as ſoon as the weather changes cold, keeping them cloſe on nights; alſo in all unfavourable weather in the day time, unleſs there is a very great ſteam, when, during its continuance, the glaſſes muſt not be kept too cloſe; and, if the weather is then cold or windy, the place where they are tilted may be defended with a mat; obſerving, as the warm weather advances, and the plants make progreſs in growth, a larger portion of freſh air muſt be admitted, to harden the runners gradually, in order to be trained out from under the glaſſes in June.

Cover the glaſſes and the whole ſurface of the bed every night with large mats, which muſt be conſtantly practiſed until the beginning or middle of June, or longer, if cold weather renders it neceſſary.

Likewiſe, in all heavy or cold rains, at any time, night or day, from the time of ridging out to the maturity of the fruit, particular care ſhould be taken to defend the whole ridge, by a good covering of mats, for much wet would ruin the crop.

Waterings in warm weather once a week or fortnight, in moderate quantities, may be neceſſary, according to the rules mentioned in the frame crops.

In a week or fortnight after ridging out, when the heat of the bed is become moderate, begin to earth the whole gradually almoſt as high as the top of the hills on which the plants ſtand, preſſing it down from time to time, that it may retain its moiſture the longer, ſo as the plants may not require much water, for the reaſons explained in *the Frame Culture*, raiſing the whole nearly equal with the ſummits of the hillocks, preſerving the middle of each rather higheſt, to prevent moiſture from ſoaking to the main ſtem, &c. as formerly cautioned.

Lining the ridges will be neceſſary in about three weeks after they are made; this ought not to be omitted, eſpecially to thoſe made in April, or early in May; and having for this purpoſe a quantity of well prepared hot dung,

add

add it to each ſide of the bed, a foot and half wide at leaſt, and full as high as the dung of the bed, and directly earth it at top to the thickneſs of that on the ridge; and thus, by the addition of the linings, that beſides the advantage of renewing the heat, it widens the bed to about ſeven feet, and forms a fine ſcope for the fibres and vines of the plants; obſerving, if there are two or more ridges ranging parallel, that if the whole ſpace between was afterwards gradually filled up with hot dung and mould, it would prove ſtill more beneficial to the plants.

Having directed ſtopping the plants at the firſt joint to procure lateral runners, if theſe laterals are alſo ſtopped at the third joint they will more ſpeedily furniſh a farther ſupply for bearing, as obſerved of thoſe in the frames.

About the end of May, or beginning of June, the firſt ridged-out plants will have nearly filled the glaſſes with their runners, at which time do not omit indulging them with a large portion of free air at all opportunities, by tilting the glaſſes every mild day two or three inches high, or in proportion to the temperament of the weather, ſo as to ſtrengthen the runners, and harden them by degrees to the full air, which, in June, when ſo much advanced in growth that they can be no longer contained within the glaſſes, muſt be trained out; the glaſſes muſt then be raiſed three inches on every ſide, on props, as for the Cucumbers, and the runners trained out with regularity; but if ſome dry reeds are previouſly ſpread upon the ſurface of the bed, for the vine to run upon, it will preſerve them and the young fruit from the damp of the earth; obſerving, the glaſſes are to remain conſtantly over each hole of plants, to protect the main ſtem and principal roots the better from wet and other inclement weather, but are now to remain day and night ſupported on the props, as above: continue alſo the nightly covering of mats for the firſt fortnight, at leaſt, after the plants are trained from under the glaſſes, to protect the tender vines till inured to the full air.

Obſerve, likewiſe, that as Melons are rather impatient of copious moiſture, it is adviſeable, after being thus trained out, to protect them with great care from exceſſive rains and cold, at all times, day or night, by proper covering; the moſt effectual means for this purpoſe is, to place oiled paper frames over the ridges, as ſoon as the vines are trained out, as directed in their culture under *Paper-frames*: however, in default of theſe conveniencies, I would adviſe to arch the bed over with hoops or rods, &c. juſt to the height of the hand-glaſſes; ſo having good thick mats or canvas cloths always ready to draw over the arches, in time of heavy or cold rains, and bluſtering winds, will be found of very conſiderable advantage, ſince a few hours violent rain often injure the plants ſo greatly, that they never after recover, ſo as to produce handſome fruit, nor bring any tolerable crop to perfection.

But when the beds are covered with paper frames, theſe remaining conſtantly on the beds, effectually defend them at all times, and admit a due portion of light, &c. to the plants.

If, however, you uſe only mats or canvas, to cover occaſionally in cold nights and bad weather, let theſe be always taken wholly off betimes every fine morning, or as ſoon in the day as the weather is favourable.

In June and July the plants will ſpread their runners all over the bed, and will ſhew fruit abundantly, at which period of ſhewing fruit very little water ſhould be given, eſpecially if there is a proper depth of earth on the beds, ſtill obſerving the ſame rules for this, as directed in the *Frame Culture*; but in very hot dry weather, after the firſt tolerable ſhew of fruit is fairly ſet, and begin to advance in magnitude, a moderate watering once a week, or ten or twelve days, whilſt the fruit are taking their growth, will encourage them, promote their ſize, and encreaſe the ſubſtance of their fleſh, being careful to apply the water moſtly towards the ſides of the bed to the extreme fibres, ſo as to preſerve the main ſtem and principal roots from receiving too much wet, and be ſure never once to overwater the beds, which might prove of very bad conſequence; but for the greater convenience of watering at this period, a deep drill may be drawn around the outſides of the bed, and the neceſſary ſupply of water poured into theſe drills, whereby the fibres will receive its benefit without wetting the leaves, branches, or fruit; but when the fruit is nearly full grown, give as little water as poſſible.

With reſpect to uſeleſs and ſuperfluous or unneceſſary branches or runners, if there is any, it is eligible culture to clear them off occaſionally, to prevent confuſion of vine, and for the proſperity of the fruit, executing it according to the rules laid down for thoſe of the frame plants.

Obſerve alſo the ſame of ſuperfluous fruit, leaving

leaving only ſuch a due quantity of the moſt promiſing and beſt-ſituated in each hole, as the plants can be expected to bring to perfection.

During the growth of the fruit, obſerve, that if the ridges are not covered with oiled paper, but only with the hand-glaſſes, &c. and the weather ſhould prove rather unfavourable or wettiſh, and that many of the fruit are ſituated on the advanced vine without-ſide of the glaſſes, it is adviſeable either to move the fruit gently under their own reſpective glaſſes; or rather, where there are any ſpare glaſſes, bring theſe and place over the fruit, contriving each glaſs to cover as many as may be convenient; for it is neceſſary thus to protect theſe fruit from injury of weather, ſupporting each glaſs two or three inches high on props; and this ſhelter of the glaſſes will greatly improve the ſize and flavour of the fruit: but in unfavourable ſeaſons oiled paper frames are the moſt effectual, becauſe, being placed all over the ridge, they defend the plants alſo, as well as the fruit, both from cold and wet; or, in cold wet ſeaſons, if there are any ſpare garden-frames and lights, theſe might be placed over the ridges, as ſoon as they are at liberty in June, July, or Auguſt, ſo to defend the plants and fruit the remainder of the ſummer, by ſhoving on the lights in all unfavourable weather, day or night.

When the fruit is encreaſed ſomewhat conſiderably in growth, it is proper to turn them every three or four days, that they may ſwell equally, and each ſide have an equal benefit of the ſun.

Their ripening is determinable by the appearances of maturity, mentioned in the culture of the early crop, obſerving alſo the ſame rules as there adviſed in cutting them for table.

*Raiſing them under Paper Frames.*

Melons are alſo fruited in great perfection under oiled paper frames, by placing them over thoſe ridges of plants which are ridged out in April and May, for they will not ſucceed in earlier crops, but for the crops juſt mentioned, they are conſiderably the moſt eligible ſhelters to place over the ridges in the middle or latter end of May, or beginning of June, after the plants have filled the hand-glaſſes, theſe being then previouſly removed entirely away, and the paper frames placed upon the bed; for theſe frames being made of due width and proper length to cover the whole ridge, and the paper being well oiled with linſeed-oil, to render it proof againſt wet, and more pellucid or tranſparent to admit the rays of light and heat in a proper degree, that they are continued conſtantly upon the ridges, whereby the plants are at all times protected from all inclement weather, either wet, wind, cold, or heat, as, although the paper admits the rays of light, &c. yet it, at the ſame time, affords the moſt agreeable ſhade from the ſcorching ſun.

Theſe frames are formed either like the roof of a houſe, or archways, like the till of a waggon, four or five feet wide, ten long, and a yard high, framed of thin ſlips of wood and lath, or broad hoops, &c. but thoſe made ridge-faſhion with two ſloping ſides, in the manner of the ridge of a houſe, are rather the moſt eligible form, becauſe on one ſide, may be made two pannels, to open with hinges towards each end, and each pannel about two feet wide, being convenient for giving air, and other neceſſary work: in either of the above forms the frames are conſtructed in an open manner, having the ribs or ſpars, a foot or fifteen inches aſunder, or at ſuch diſtances as to admit of paſting the ſheets of paper commodiouſly; but previous to paſting on the paper, draw lines of packthread, &c. acroſs corner-ways from rail to rail of the frame, drawing other lines interſecting or croſſing the firſt, theſe being neceſſary for ſupporting the paper the more effectually againſt the power of wet and wind; then having ſome ſtrong printing paper, let it be a little damped, that it may not ſink in hollows after it is fixed on the frame; therefore, as ſoon as it is damped, paſte it on the frame; two large ſheets will generally range from bottom to top, paſting it ſecurely to the rafters and rails, and ſo as the middle of each ſheet reſts upon the interſections of the packthread lines; and when the paper and paſting is thoroughly dry, bruſh the outſide all over lightly with boiled linſeed-oil, then ſuffer the frame to ſtand in a dry ſhed till the whole is perfectly well dried before it is uſed. See PAPER FRAMES.

But for want of regular made frames, a quantity of hoops or rods might be placed acroſs the ridges of plants arch-ways, ſticking both ends into the earth, about a foot aſunder, and two high, ſo drawing lines of packthread along from hoop to hoop, both to ſteady the arches, and help to ſupport the paper;

paper; then paſte a quantity of ſtrong paper in large pieces about three or four ſheets in width, and in length proportionable to that of the ridges they are to cover; then oil them with linſeed-oil, and, when thoroughly dry, ſpread them over the hoop-arches, and ſecure them by lines drawn from end to end; and that for the admiſſion of air, and doing other neceſſary work, one ſide of the paper is readily turned up at bottom as far as convenient.

In reſpect to the mode of uſing either of theſe paper ſhelters, the plants are previouſly to be raiſed in hot-beds, under frames and lights, exactly at the time and manner, as directed for the hand-glaſs crops, and to be ridged out alſo at the ſame times and manner there mentioned; obſerving, that, in default of hand-glaſſes, theſe paper frames may be uſed as ſoon as the plants are ridged out; but in this caſe the ridging out ſhould not be performed till May: but the moſt ſucceſsful way is, when there are hand-glaſſes ſufficient, to place theſe glaſſes over the plants at firſt ridging out, as directed in the hand-glaſs culture, managing them in the ſame way in every reſpect, till the plants have filled the glaſſes with their runners; then remove the glaſſes away, and place over the paper frames.

When theſe ſhelters are placed over the plants, free air muſt be admitted in proportion to the temperature of the ſeaſon, either by opening the pannels leſs or more, according to the warmth of each day, or by tilting one ſide of the frames at bottom, &c. for the article of freſh air muſt not be omitted at all opportunities, particularly when the plants ſhew fruit, the air being not only neceſſary to ſtrengthen the plants, but alſo to aſſiſt in the impregnation of the fruit, for the reaſons explained in the early Cucumber work; and towards the end of June, when the ſeaſon is warm, the frames may be raiſed at bottom about four inches.

It is alſo neceſſary to defend the plants over the above ſhelters with mats every night till towards the middle of June; likewiſe, occaſionally, in all hard rains, day or night.

Theſe paper ſhelters never laſt but one ſeaſon, that is the paper; but as to the frames, they, with care, will continue uſeful ſeveral years, ſo muſt be freſh papered every ſpring, in proper time to be ready to place over the beds.

*Raiſing them in Bark Hot-beds.*

Having before advanced hints reſpecting the merit of tanner's bark hot-beds in the culture of Melons, obſerve, we propoſe them principally as fruiting beds; that is, previouſly raiſing the plants in dung hot-beds, as already directed, and then tranſplanting into the bark-beds.

With reſpect to the merit of theſe ſort of hot-beds for this purpoſe, it muſt be conſidered, that as the Melon plants are generally between three and four months from their firſt appearance till they produce ripe fruit, and they all the time require the conſtant aid of artificial heat, which, though they are fruited in great perfection in that of dung, i. e. dung hot beds, yet thoſe of tanner's bark being conſiderably of more durable and regular heat, the plants by that aid may ſtill be fruited to greater advantage, and with leſs trouble, becauſe, if made entirely of new tan, no lining, or but very little, will be neceſſary, nor is there ſuch danger to be apprehended from ſteaming or violent heat, as in dung hot-beds; but it muſt be remembered, that the purchaſe of the tan renders theſe kind of hot-beds more expenſive than dung, though, if both theſe materials are obliged to be purchaſed, and the tan can be obtained within a moderate diſtance, there is but an inconſiderable difference in the expence; for you cannot have a good cart-load of hot dung brought home for leſs than three ſhillings, and in ſome places five or ſix, or more, and you may have ſixty buſhels of tan, about as much as three horſes can draw, for three half crowns.

But, in caſe of ſcarcity of new tan for the above purpoſe, the waſte or caſt-off bark of the ſtoves, mixed with a quantity of new, might be uſed, provided, however, the old tan is not become quite earthy; ſo mixing one half old to one of new, which will form a moderately ſtrong and durable heat, and will anſwer for beds made not earlier than the middle of February, or beginning of March.

Or, for the latter crops, beds might be formed entirely of caſt-off bark, provided, as above obſerved, it is not become very earthy, and its fermenting property not quite exhauſted; which, if not, when freſh worked up, and formed again into a bed, will renew its heat, though in a moderate degree, therefore ſhould not be uſed for beds earlier than March and April, and which, if made in a pit formed of poſt and planking, ſo as to admit of a ſubſtantial lining of hot dung

to each ſide in ſix weeks or two months after making, would be an additional advantage to the plants.

Obſerve, that either the above mentioned bark-beds for the culture of Melons, muſt be made in ſome kind of pit, or frame, to confine the bark, which otherwiſe could not be formed into a bed, either in a bark-pit covered with glaſs lights, as exhibited in the article BARK-PIT; or, in default of ſuch a pit, one might be formed of poſt and planking, of width and length for one or more large three-light frames, and three feet and a half deep, to contain that ſubſtance of bark, and may either be ſunk half way in the ground, or not ſo much, according as the ſoil is dry or wet; but it would be moſt convenient to have it not ſunk more than a foot, for the advantage of adding a lining of hot dung to the ſides, if there ſhould be occaſion; I would, therefore obſerve, that a planked pit, for the culture of Melons, may be rather preferable to brick or ſtone, becauſe if you ſhall find it neceſſary to line the beds, by applying hot dung againſt the outſide of the planking, its heat will readily penetrate ſufficiently to recruit the declining heat of the bed; for as the Melons are to be planted in the full bed, and not in pots, as practiſed to pine-apple plants, there is no ſtirring up the bark to revive the heat as in ſtoves, and a lining may probably be neceſſary to thoſe beds, where caſt-off bark is uſed, or perhaps ſometimes one lining to thoſe beds made of new tan, may be of advantage, juſt when the fruit is ſetting and taking their firſt growth; on theſe conſiderations contrive the pit ſo as to admit of lining the ſides almoſt or quite to the bottom.

The time of year to begin the culture of Melons in theſe ſort of hot-beds, is the ſame as mentioned in dung hot-beds, and the plants ſhould be raiſed in a nurſery-bed as there directed; and when of the proper age and ſize, as there obſerved, tranſplant them into the bark-beds to remain to fruit.

Theſe fruiting-beds ſhould be made a fortnight or three weeks before-hand, to acquire a proper heat in due time for the reception of the plants from the nurſery hot bed, at their proper period of growth. Let the beds be made the full width and length of the pit allotted for them, and three feet at leaſt deep; but if caſt-off bark is uſed, three and a half depth in bark will be requiſite. As ſoon as made, cover the bed with the proper frames and glaſſes, to defend it from rains; and in about a fortnight it will be arrived to a proper temperature of heat; then earth it at top, as directed for the dung-beds, and the earth being warm, ſet two plants with their ball of earth entire, juſt under the middle of each light, give a little water, and manage them according to the former directions.

But if the bed is to be made moſtly of caſt-off bark, as it will be ſomewhat of a mouldering texture, and of but moderate heat, inſtead of earthing it as above obſerved, you may try the ſucceſs of planting intirely in the bark, without any earth at all. Let the bed be of the above mentioned dimenſions, and covered with the frames and lights, and in about three weeks it will be warm enough either to receive ſeed, or plants, firſt making holes in the middle of the bed, one immediately under the middle of each light, ſix or eight inches deep, and twelve or fifteen broad, fill them with rotten or finely pounded bark, forming each a little hollow, baſon-like, in which either ſow ſeed, and when the plants are a week or two old, thin them to two of the beſt in each hole, and there let them remain to fruit: or, to make the moſt of the bed, put in plants raiſed to a proper age, as in the dung hot-bed culture.

The plants being tranſplanted into either of the above bark hot-beds, obſerve the lights are to be kept conſtantly on, being careful to give the plants a proper ſhare of warm air at all opportunities, as the weather permits, according to the former rules.

It muſt be remarked, that the plants will not require much water in theſe hot-beds, as bark continues to ſupport a fine moiſt heat, of a very agreeable nature to the growth of moſt ſorts of plants, ſo that the Melons will be found to ſucceed with a very moderate ſupply of water, and the leſs the better, both for the continuance of the heat of the beds, as well as for the advantage of the plants and fruit.

Should you find the heat of the beds conſiderably declined when the fruit is ſetting, or taking its firſt growth, a good lining of hot dung againſt the outſides of the pit will be very beneficial.

*Saving the Seed.*

As to ſaving Melon ſeed, we need only farther obſerve here, that it ſhould be ſaved only from the very fineſt fruit of the reſpective varieties, and ſuch that has a firm and

highly flavoured fleſh; this ſhould be particularly obſerved when the fruit is ſerved at table, and the right ſeed properly reſerved in its own pulp, and ſent to the gardener; which, after lying in the pulp a few days, may be waſhed out, and all the heavy or good ſeed which ſink in the water are to be preſerved, dried, and put up for ſaving.

It will retain its germinative property ten or twelve years, but when from about three to five years old, is in its beſt perfection for uſe, for reaſons already given.

CUCURBITA, the Gourd and Pompion, and alſo the *Citrullus* or Water Melon.

The plants are herbaceous annuals, moſtly of trailing growth, extending from about five or ten, to forty or fifty feet in length, adorned with luxuriant ſimple foliage, and large monopetalous bell-ſhaped flowers, ſucceeded by enormous fruit, and are cultivated in our gardens, ſome by way of curioſity or variety, and ſome for the ſake of their fruit, particularly the Water-Melon. See CUCURBITA CITRULLUS.

Claſs and order, *Monoecia Syngeneſia.*

*Characters.*] CALIX, male and female flowers apart, having a monophyllous bell-ſhaped cup, terminated at the brim by five briſtles. COROLLA, is monopetalous, bell-ſhaped, five-parted, and adheres to the calix. STAMINA, in the males, three connivent filaments, and linear reptant antheræ. PISTILLUM, a large germen under the female corolla, a conical, trifid ſtyle, and a large trifid ſtigma. PERICARPIUM, a large fleſhy fruit of three membranaceous cells, and numerous compreſſed obtuſe ſeeds, in a double ſeries.

We ſhall firſt exhibit the Gourd and Pompion tribe under one head, and the Citrullus, or Water-Melon, in another. See CUCURBITA CITRULLUS.

Of the Gourd and Pompion kinds there are about five ſpecies, each of which admitting of ſeveral varieties in the form and ſize of their fruit; ſome aſſuming a long figure, obtaining from about two to five or ſix feet in length, and one or two round; others aſſume a round form, and as large as a half peck, or even a peck, or almoſt a half buſhel meaſure, and other various forms and magnitudes down to the ſize of an orange; and the plants grow ſo rapidly, that riſing from ſeed in ſpring, extend from about five or ten, to forty or fifty feet each way by Auguſt and September, at which times they perfect their fruit, and in October and November following they totally periſh; ſo that they are of but little more than ſix months duration. They are exotics of America, and other diſtant countries, but are hardy enough to grow here in the full ground, from May till October.

The ſpecies are,

[1]CUCURBITA *Lagenaria.*

*Bottle Gourd.*] Cucurbita with trailing, thick downy ſtalks, branching into many ſpreading runners, extending along the ground fifteen or twenty feet in length, large, roundiſh, heart-ſhaped, indented, woolly leaves, glandulous at the baſe, and large white flowers, ſucceeded by long incurvated whitiſh yellow fruit, obtaining from about two to five or ſix feet in length, and about nine to eighteen or twenty-four inches round, having a ligneous durable ſhell, that having the pulp ſcooped out, is uſed for holding water, &c. hence the name *Lagenaria* or Bottle-Gourd.

*Varities of this are*] Common long-fruited Bottle-Gourd——Long protuberant bellied Bottle-Gourd—Long ſickle-ſhaped Bottle-Gourd—Long taper Bottle-Gourd—Long turbinated Bottle-Gourd.—All theſe varieties if forwarded in ſpring in hot-beds, and planted out in May into the natural ground, or rather upon holes of hot-dung under hand glaſſes, to be ſheltered during the cold weather; the fruit will obtain a large growth, and ripen perfectly. Some of which have acquired ſuch a prodigious magnitude, as when ſcooped, the ſhell has contained twenty-two gallons of liquid; and in America, where they grow in great abundance, the ſhells are converted into many uſeful domeſtic utenſils. The fruit, while quite young and tender, is alſo very commonly uſed in both Indies as culinary diſhes, both to eat alone, and as ſauce to fleſh meat.

[2]CUCURBITA *Pepo.*

*Pepo or Pompion, commonly called Pumpkin.*] Cucurbita with trailing, ſtrong, rough ſtalks, branching into numerous runners, ſpreading along the ground, from about ten to forty or fifty feet each way, garniſhed with large, roundiſh, lobated, rough leaves, and yellow flowers, ſucceeded by large, round, ſmooth fruit, of different forms and ſizes in the varieties, ſome as big as a peck, or almoſt a half buſhel meaſure, others conſiderably leſs, and ſome not bigger than an orange, ripening to a yellow, and ſometimes a whitiſh colour, &c.

*Varieties*

*Varities of this are*] Common large round-fruited yellow Pompion--Oval yellow Pompion—Oblong yellow Pompion—Whitiſh fruited Pompion—Marbled Pompion—Small round Pompion—Orange ſhaped Pompion—Pear ſhaped Pompion--Turbinated Pompion--Spherical, or ſemi-globular Pompion—Egg ſhaped Pompion—Striped roundiſh Pompion—Striped egg ſhaped Pompionr—Striped turbinated Pompion.—Striped pear-ſhaped Pompion.

This ſpecies and varieties are the moſt hardy, as well as conſiderably the moſt extenſive in their growth, as a ſingle plant, if properly encouraged, is ſuppoſed will overſpread ten or fifteen rods of ground, and produce a great number of fruit; which, when young, is generally a mixture between a deep blue and pale white, but change as they encreaſe in volume. The plants are cultivated in England principally for curioſity, the fruit being rarely uſed; though in America, Aſia, and Africa, theſe, as well as the Gourd, make great part of the food of the poorer people during the hot months; and, if gathered when not much bigger than a hen or gooſe egg, boiled and properly ſeaſoned with butter, vinegar, &c. they eat tolerably palatable by way of ſauce to butcher's meat; they are alſo uſed in ſoups; but here in England they are ſeldom uſed till grown to maturity, when they make a hole on one ſide, and diveſt the pulp of all the ſeeds, then mix it with ſliced apples, milk, ſugar, ſome grated nutmeg, &c. and thus make a kind of pudding, prepared in the ſhell, and bake it in an oven, which is commonly called pumpkin pye, and for which purpoſe the plants are cultivated by the country people in many parts of England, who plant them upon old dung-hills, or compoſt heaps, or ſuch like places; for the ſeed, if not ſown till May, will grow in the open ground; however, to have them in more early perfection, it is beſt to forward them in a hot-bed in April, and plant them out in the middle of May. See their *Culture*.

3 CUCURBITA *Verrucoſa*.

*Warted Gourd*.] Cucurbita with trailing ſtalks, very branchy and ſpreading, running upon the ground ten or fifteen feet each way, large lobated leaves, and yellow flowers, ſucceeded by roundiſh, knobby-warted, white fruit, of different forms in the varities; and all of moderate ſize.

*Varieties are*.] Roundiſh Warted Gourd—Oblong Warted Gourd—Flat Warted Gourd—Bottle-ſhaped Warted Gourd—Orange-ſhaped Warted Gourd——Lemon Warted Gourd.

Theſe varities are alſo all uſed, while growing, as culinary, in many parts of America.

CUCURBITA *Melopepo*.

*Melopepo, or Erect Gourd, or Squaſh*.] Cucurbita with an erect ſtrong ſtalk ſeveral feet high, rarely ſending forth ſide runners, but becoming buſhy upward, adorned with large lobated leaves, and the flowers ſucceeded by depreſſed knotty fruit, both of white and yellow colours, and of different forms in the varities, but chiefly of a moderate growth.

*Varieties are*] Common broad flat Squaſh—Buckler-ſhaped Squaſh—Conical Squaſh—Citron-ſhaped Squaſh—Flat-ſided Squaſh—Turbinated Squaſh—White-ſtriped Squaſh—Yellow-ſtriped Squaſh.—All of which varieties grew with erect ſtalks; obſerving, however, that by ſaving the ſeed ſeveral years in the ſame ground, they are apt to vary, and aſſume a trailing growth, and put forth runners like the other ſpecies. The fruit when nearly half-grown, being boiled, is by ſome people eſteemed very delicate; but the Americans generally pluck it for uſe ſoon after the falling off the flower, or when the fruit is the ſize of a walnut, or at moſt not bigger than a hen's egg.

CUCURBITA *Lignoſus*.

*Ligneous-ſhelled Gourd, often called Calabaſh*.] Cucurbita, with trailing ſtalks, branching into runners, extending many feet each way, large, lobated, rough leaves, and yellow flowers, ſucceeded by roundiſh moderate ſized ſmooth fruit, of different forms in the varieties, and the ſhells become hard and woody.

*Varieties of this are*.] Roundiſh bottle-ſhaped ligneous Gourd, being almoſt the ſize and ſhape of quart bottles—Pear ſhaped fruit—Orange-ſhaped yellow fruit.

Among the varieties of the laſt four ſpecies, there are ſome whoſe fruit are of the ſize, ſhape, and colour of oranges, lemons, and pears, which appear extremely curious when growing. Theſe are commonly denominated —Smooth yellow Orange Gourd—Rock or carbuncled Orange Gourd—Stone-coloured Orange Gourd—Lemon Gourd—Rock Lemon Gourd—Yellow pear-ſhaped ſtriped Gourd—Pear-ſhaped white-ſtriped Gourd, &c.

But it muſt be obſerved, that the varieties of all the ſpecies of Cucurbita are amazingly variable in their fruit; that without particular care in cultivating them ſeparate, they ſeldom

continue the ſame longer than two or three years; for thoſe of each ſpecies vary leſs or more from ſeed, both in figure, ſize, and colour.

The plants in general have ſtrong, thick, ſucculent ſtalks; the leaves very large, elevated on long foot-ſtalks, ariſing alternate from the joints of the ſtalks and branches; and the flowers are male and female apart on the ſame plant, proceeding from the axillas of the leaves, and the germen of the female flowers becomes the fruit. See the *Characters*.

All theſe ſpecies of Gourds and Pompions, &c. and reſpective varieties, obtain eſtimation principally as plants of curioſity, for the ſingularity of their growth and fruit, and are often admitted in curious gardens, both as plants of variety and ornament; and as ſuch, if properly diſpoſed, will exhibit a ſingular appearance, raiſing them in a moderate hot-bed in April as hereafter directed, and tranſplanted into different parts towards the middle or latter end of May, allowing them an open ſunny ſituation; ſo that ſome may be diſpoſed in open vacant ſpaces contiguous to lawns and ſpacious walks, training ſome along upon the ſurface of the earth, according to their natural growth, others may be trained about tall ſtout ſtakes fixed ſecurely in the ground, and ſome may be conducted over buſhes, or up the ſtems of ſhrubs and trees, and their courſe directed among the extreme branches. They have likewiſe a fine effect when trained upon arbours of lattice work, or railing, which they will ſoon overſpread; and they alſo form a fine variety trained againſt a wall, paling, or any kind of fence; in all of which methods of training they will bear plentifully, but the fruit is the moſt conſpicuous and ornamental when the plants are trained upon ſome kind of ſupport, which is more particularly neceſſary to be practiſed in all thoſe ſorts denominated Gourds.

As the plants in general delight in a fat ſoil, they, when planted on old rotten dung-hills, generally make amazing progreſs, but more particularly the pompion kinds, where they will ſpread wonderfully, and produce abundance of fruit in its fulleſt perfection.

But the Bottle-Gourd, Warted-Gourd, Melopepo or Squaſh, and the Ligneous Gourd or Calabaſh, are commonly the moſt fruitful when trained upon ſome ſupport, and the fruit obtains the largeſt ſize, and more eſpecially the Bottle-Gourd.

As the fruit of theſe plants are but of little eſtimation in England for culinary uſes, our gardens furniſhing many other eſculent plants, roots, and fruits, of a more palatable flavour; a few plants of each ſort ſhould, therefore, only be cultivated, becauſe they require ſo much room to ſpread.

*Their Propagation, Culture, &c.*

All the ſpecies of Gourd and Pompions, and their reſpective varieties, are raiſed from ſeed ſowed annually in April and beginning of May, either by aid of artificial heat, or without; but the plants forwarded in a hot-bed till about a month old, come into fruit a month or ſix weeks earlier, and will ripen ſooner in proportion.

Therefore, the ſeed may either be ſown in a moderate hot-bed in April, half an inch deep; and when the plants have three or four leaves, tranſplant them in May or early in June into the open ground, or upon holes of hot dung, under hand-glaſſes, &c. which will forward the plants conſiderably.

Or for want of hot-beds, the ſeed may be ſown in the full ground in the firſt or ſecond week in May, but not ſooner. The *Cucurbita Pepo*, or Pompion, in particular, ſucceeds rather better than any of the ſorts by this method; the third, fourth, and fifth ſpecies will alſo ſometimes ſucceed tolerably in fine dry ſeaſons; but the firſt ſpecies, *Cucurbita Lagenaria*, rarely ever comes forward enough to produce any tolerable ſized fruit, unleſs forwarded at firſt by artificial warmth, and indeed all the other ſorts of Gourd arrive much ſooner to perfection, if brought forward at firſt in a hot-bed. However, in default of ſuch conveniences, the ſeeds may be ſown at the above mentioned times in the natural ground, where it is deſigned the plants ſhall remain to fruit, chuſing rich ground in a ſunny expoſure, which ſhould be well dug and formed into ſhallow holes, baſon-like, as for the pickling cucumbers, at conſiderable diſtances, ſowing three or four ſeeds, half an inch deep in each hole; but, if you have any hot dung to ſpare, it would be of much advantage, that in the places where you intend ſowing the ſeed, to dig holes two feet wide, and fifteen inches deep, fill them with the hot dung, and earth it over ſix or eight inches deep, ſo forming the earth hollow, put in the ſeed as above; then, in either method of ſowing, if there are any ſpare hand-glaſſes, it would alſo be of much

ſervice

ſervice to place one over each hole occaſionally in cold nights and bad weather, or for want of theſe, may cover on nights with large garden pots, &c. whereby the plants will come up ſooner, and continue a ſurer growth than if fully expoſed, obſerving to leave only one of the beſt plants in each hole, giving plenty of water in dry warm weather, and they will ſpread themſelves conſiderably in June and July, and produce ripe fruit in Auguſt and September.

But, as the principal merit of all theſe ſort of plants conſiſts in their fruit, both for uſe and ornament, therefore, to have them in fruit as early as poſſible in ſummer, I ſhould adviſe, where convenient, to ſow and forward the plants in a hot-bed; that is, ſow the ſeed in April in any of the cucumber or melon hot-beds, under glaſſes, &c. or, if ſown ſeparate in a moderate hot-bed under a ſmall frame, or hand or bell-glaſſes, or oiled paper lights, they may be more readily hardened by degrees to the full air; and when the plants raiſed in either method are come up a few days, and have expanded their ſeed-leaves, they ſhould be taken up and pricked down, either in the earth of the bed, about four inches diſtant, or rather in ſmall pots, one plant in each, ſo plunging them in the bed; being careful, if in a bed by themſelves, to admit a large portion of free air every mild day, to ſtrengthen and harden them gradually, preparatory to their tranſplantation into the full ground, which is to be effected in May or early in June, when the plants have three, four, or five leaves, previouſly digging the ground, and forming ſhallow holes a foot wide, in the allotted places, and tranſplant the plants with a ball of earth about their roots, one plant in each hole, giving directly ſome water; and, to the tender ſorts, the occaſional ſhelter of a hand-glaſs, &c. on nights during the cold weather, will prove beneficial to the plants; let them, however, at any rate, have occaſional ſhade the firſt week from the noon-day ſun.

As, however, the firſt ſpecies, *Cucurbita Lagenaria*, is rather more tender than the other ſorts, it would be highly proper in tranſplanting them, as above, where they are finally to remain, to indulge them ſtill with a farther aid of artificial heat, and occaſional ſhelter of glaſſes, otherwiſe they rarely come forward enough to produce fruit of any conſiderable ſize; therefore, in the allotted places dig holes two feet wide, and one and a half deep, filling each hole with hot dung, and earth them ſix or eight inches deep, put in the plants, and cover them with hand-glaſſes till their runners advance from under them, managing them nearly as directed for the hand-glaſs crop of cucumbers.

I would likewiſe obſerve, that as the Warted-Gourds, &c. are alſo rather of more tender quality than the Pompions, it is therefore alſo adviſeable, where there is hot dung and hand-glaſſes to ſpare, to treat them in their final tranſplantation as directed above for the *Cucurbita Lagenaria*, by which practice you will obtain them in fruit much earlier in the ſummer.

All the ſorts of theſe plants require a plentiful ſupply of water in dry weather, eſpecially after they have begun to run. Let them, therefore, be duly ſupplied in dry ſeaſons, and they will extend to a greater diſtance, and produce a great quantity of fruit.

When theſe fruit are deſigned to be uſed as culinary, for boiling, they ſhould be gathered when quite young, while the outſide tegument, or rind, is perfectly tender, they will then boil exceedingly ſoft, and have an agreeable flavour.

To ſave ſeed of theſe ſpecies, it muſt be taken from the ripe fruit in autumn; the fineſt and the moſt perfect ripened fruit of Auguſt and September ſhould be choſen, and the ſeeds diveſted of the pulp, as obſerved of the cucumbers and melons.

*Second Head.*

CUCURBITA-CITRULLUS, the Citrul, or Water-Melon, *(Citrullus.)*

The *Citrullus* is now retained as a ſpecies of *Cucurbita*, according to the Linnæan arrangement, which by Tournefort, Miller, and other former botaniſts, was conſidered as a diſtinct genus, under the title of *Anguria*; but its characters being proved the ſame as the *Cucurbita*, or Gourd, it is properly a ſpecies of that genus.

Claſs, order, and character, the ſame as the *Cucurbita*.

There is but one ſpecies, viz.

CUCURBITA *Citrullus.*

*Citrul, or Water-Melon.*] Cucurbita, with trailing ſlender ſtalks, branching into many runners, extending ſix or eight feet every way, ornamented with large leaves divided into many parts; and yellow male and female flowers apart, the females ſucceeded by large round ſmooth fruit, replete with a watery cooling

cooling juice; hence denominated Water-Melon.

*Varieties of this are*] Large round red-fleſhed Water-Melon—Large round white-fleſhed Water Melon—Large oblong Water-Melon—Small round Water-Melon, &c.

The large varieties of this fruit obtains a monſtrous volume, frequently growing as large as half peck and peck meaſures; but theſe very large kinds rarely ripen in any degree of perfection in England; the moſt proper ſorts, therefore, for Engliſh culture, are the ſmall round kinds, which will ripen freely, and acquire a rich flavour, and of which there are both red and white fleſhed kinds.

The plants are tender herbaceous annuals from the hot parts of the world, and nearly of the temperature of the *Cucumis Melo*, or Muſk-Melon, and, like them requiring the aid of artificial heat and ſhelter, to bring the fruit to perfection in this country.

Their ſeaſon of ripening in England is Auguſt and September

Theſe fruits by their cooling and diuretic quality are ſo very beneficial in hot climates, that they are greatly cultivated in Portugal, Spain, and the Levant; alſo in Perſia and Egypt, and other parts of Aſia and Africa, and the warm parts of America; in all of which countries they grow freely in the open ground, and ripen in the greateſt perfection.

In England, however, notwithſtanding our aids of artificial heat and ſhelter, this fruit, on account of its watery quality, and ſometimes for want of proper culture, according to its nature, is often ripened but indifferently, which is the cauſe of its not being in general eſteem. But by aid of ſubſtantial hot-beds, under conſtant ſhelter of frames and glaſſes, and the beds ſupported in a conſtant good heat, the fruit may be ripened in full perfection; which, if effected in due time in autumn, whilſt the warm weather continues to give it flavour, it is very delicious eating, and is accounted exceeding wholeſome.

### *Propagation and Culture.*

The propagation and culture of all the varieties of Citrullus is nearly the ſame; as for the muſk-melon, they are raiſed annually from ſeed ſown in hot-beds, under frames and glaſſes in February or beginning of March, as for the muſk-melons, and when the plants have come up a few days, prick them in pots (thirty-twos) two plants in each, plunging them in the bed, obſerving to ſtop the plants alſo at the firſt joint; and when they begin to ſhoot runners, tranſplant them into a large hot-bed, alſo under frames and lights, where they are to remain to fruit.

As theſe plants are nearly of the ſame temperature, and nature of growth as the cucumber and muſk-melon, the ſame degree of hot-beds, method of ſowing, raiſing, and nurſing the plants, is here to be obſerved; and their whole management, in reſpect to giving air, covering the glaſſes on nights, giving water, and ſupporting the heat by linings, &c. is alſo exactly the ſame. The ridging out the plants into the fruiting hot-beds is alſo the ſame as the muſk-melon, obſerving to make the hot-beds ſubſtantial, for one or more of the largeſt three-light frames; for, as the plants ſpread conſiderably, ſhould have as much room as poſſible; earth the bed twelve or fifteen inches thick in hillocks; but as one hole of plants is ſufficient for each, a three-light frame, therefore, lay only one hillock of earth juſt under the middlemoſt light, earthing the other parts only about three inches thick at preſent, ſo when the earth is warm, put in one pot of two plants in each hill of earth; though one plant, if it thrives, will ſufficiently fill the frame, for they ſpread at a great rate, and unleſs they have full ſcope, they will make little progreſs in fruiting.

When they are thus ridged out, obſerve that as the glaſſes muſt be continued conſtantly on the frames, do not omit giving air at all opportunities, agreeable to the rules exhibited in the cucumber and melon ſame culture; likewiſe cover the glaſſes every night with mats as for them directed; give alſo frequent moderate waterings, and earth the bed gradually to the depth of the hillock on which the plants ſtand, and conduct the vine and runners in proper directions, ſo as to fill all the places within the frame. The heat of the bed muſt alſo be ſupported with great attention, by proper linings of hot dung; obſerve this all along, to forward the plants as much as poſſible, and it is particularly neceſſary, when the plants begin to ſhew fruit, and whilſt it is taking its firſt growth, until almoſt as big as a man's double-fiſt, for without a conſtant bottom heat till that period, it will be impoſſible to bring this kind of Melon forward enough to ripen in good perfection in England; therefore, let it be a rule to maintain a conſtant heat in the bed, as above,

above, and continue the conſtant ſhelter of the glaſſes, tilting them all fine days, to allow a proportionable ſhare of air; and in ſcorching ſunny weather, a ſlight ſhade of a mat, or a little looſe hay, for two or three hours in the middle of the day will be neceſſary, together with a moderate portion of water once a week or fortnight; and with this culture, the fruit will readily attain perfection in any part of Britain, and before it is late in autumn; for unleſs they ripen in Auguſt and September, they will be devoid of flavour.

The aid of bark hot-beds would be very beneficial in the culture of this ſpecies, as we formerly obſerved in the muſk-melon culture.

It muſt be remarked, that theſe plants can never be fruited in any degree of perfection under hand or bell-glaſſes, &c. as practicable for the latter crops of muſk-melons.

With reſpect to the tokens of ripeneſs of theſe fruits, it muſt be remarked, that they ſeldom impart that very fragrant ſmell peculiar to muſk-melons, nor, like them, do they often crack or recede from the foot-ſtalks; but they ſometimes change a little yellowiſh, and the top becomes ſoft or pliable to the touch, and by ſmelling cloſe to that part, they ſometimes alſo diſcover their maturity by the emiſſion of a little fragrance.

The ſaving ſeed of this ſpecies is, as obſerved of the Muſk-Melons, to be effected always from the fineſt and moſt perfectly ripened fruit, treating it in the ſame manner.

CULINARY Plants. Plants or herbs that are uſed in the kitchen for boiling, ſtewing, or any other culinary purpoſe in cookery.

CUPRESSUS, the Cypreſs Tree.

This genera conſiſts of hardy evergreen and decidious trees, of beautiful pyramidal growth, and are proper both as timber trees, and for ornamental plantations, being very pictureſque in their general habit, extending their branches regularly all around from top to bottom of the ſtem, cloſely decorated with ſmall narrow thick leaves, and amentaceous male, and conous female flowers, ſucceeded by round ſcaly fruit, called cones. See CONUS.

Claſs and order, *Monoecia Monadelphia.*

*Characters.*] CALIX, male and female flowers apart on the ſame plant; the males an oval katkin, and the females a roundiſh cone, each of ſeveral ſcales, and each ſcale ſerving as a calix to one fructification. COROLLA, no petals; STAMINA, no filaments, but four anthoræ at the bottom of each ſcale. PISTILLUM, a ſcarcely viſible germen, and very ſhort ſtyle. PERICARPIUM none, the ſeed being involved only by the tough ſcales of the calix, forming a roundiſh cone.

There are about three diſtinct ſpecies of theſe trees common to the Britiſh gardens, two evergreens and one deciduous; and one of the former admits of three beautiful varieties, differing in ſtature and habit of growth.

The ſpecies are,

CUPRESSUS *Sempervirens.*

'*Evergreen Common Cypreſs.*] Cupreſſus, with an upright ſtrait ſtem, cloſely branching all around almoſt from the bottom upwards, into numerous quadrangular branches; obtaining, in the different varieties, from about fifteen or twenty, to forty or fifty feet ſtature, and very cloſely garniſhed with very ſmall, narrow, erect evergreen leaves in imbricatum, and flowers and fruit from the ſides of the branches.

*Varities of this are,*

*Evergreen common upright Cypreſs*—ariſing from about fifteen to twenty feet high, and with all its branches aſſuming an upright direction, often growing in a cloſe pyramidal form.

*Evergreen horizontal ſpreading Cypreſs*—— ariſing thirty or forty feet high, and with all the branches ſpreading widely in a horizontal direction.

*Evergreen ſmall-fruited Portugal Cypreſs, often called Cedar of Goa*—obtaining near twenty feet ſtature, having all its branches ſpreading irregularly in a ſomewhat horizontal poſition, frequently bending downwards, and the leaves ending in ſpines.

All theſe varieties of *Cupreſſus Sempervirens* are inhabitants of the Levant, and grow in great abundance in Spain and Portugal, alſo in the iſland Crete, or Candia, where there are vaſt plantations of them, and are uſed as their moſt common timber, more particularly the horizontal kind, as being the largeſt grower, the timber of which is ſuppoſed to be of many hundred years duration in any kind of buildings, for it is ſaid to reſiſt the worm, moth, and all putrefaction. The trees in general are alſo beautiful, in their growing ſtate, and ſo hardy that they proſper here in almoſt any ſoil, but are obſerved to be particularly thriving in any gravelly or ſandy ground, and may be employed to great advantage in ornamental plantations for the embelliſhing gardens

dens and parks. The firſt of theſe varieties was long the moſt common in England, and on account of its erect cloſe pyramidal growth, was formerly trained into regular figures, by ſhearing it annually in ſummer.

[2]CUPRESSUS *Thyoides.*

*Thyoides, or Evergreen arbor-vitæ-leafed American Cyprus, ſometimes called White Cedar.*] Cupreſſus, with an upright ſtem, branching out regularly into numerous ancipal, or two-edged branches, and ariſes twenty or thirty feet high, ornamented with flat evergreen leaves, imbricated like arbor vitæ, and ſmall blue cones the ſize of juniper-berries.

CUPRESSUS *Diſticha.*

*Diſtichous-leafed American Deciduous Cypreſs.*] Cupreſſus, with an erect trunk, attaining a large bulk, branching wide and regular, and grows fifty or ſixty feet high, fully garniſhed with ſmall ſpreading deciduous leaves, arranged diſtichous, or along two ſides of the branches. And, conſidered as a deciduous tree, makes a moſt beautiful appearance in ſummer.

The flowers of all theſe trees ariſe principally from the ſides of the branches, but they make but little appearance, and the fruit is univerſally ſmalliſh, cloſe, round cones, which, on large trees, ſometimes ripen in England, though not always furniſhed with good ſeeds, ſo they are commonly procured from abroad for ſowing.

All theſe trees being beautiful in their general growth, and very ornamental in their ſmall, but cloſely placed foliage, are moſt proper to be employed in all ornamental plantations, and have a fine appearance either thinly grouped with other trees, on the ſides of ſpacious lawns, or to border grand plantations; likewiſe to aſſiſt in forming detached clumps, or to be ſtationed here and there as ſingle objects, or in ſmall groups by themſelves, of from two to five of different ſorts, in extenſive lawns, parks, and other graſs ground; they are alſo choice furniture to be employed in aſſemblage in forming rural avenues, and grand rural walks, and the evergreen kinds, by their pyramidal form, are peculiarly adapted for embelliſhing the grounds contiguous to ornamental garden buildings, temples, and other ſacred ſtructures, in any part of pleaſure grounds; and ſingle trees placed in large breaks or opens, in the excurſions of ſpacious ſerpentine walks are very ornamental.

As ſome of the ſorts acquire a conſiderable ſtature and bulk, and arrive to timber, they may alſo be introduced among foreſt trees, in the moſt conſpicuous parts of eſtates, to the emolument of the owner, as well as to improve the beauty and elegance of his plantations.

The ſeaſon for planting, or tranſplanting theſe trees is the ſame as for other hardy evergreens, and thoſe of the deciduous tribe. See EVERGREEN and DECIDUOUS TREES.

In their culture it is adviſeable to ſuffer them all to retain their natural growth, in which they will exhibit the more picturesque appearance.

*Propagation of all the ſorts.*

They are all raiſed abundantly by ſeeds; they will alſo ſometimes grow by cuttings of the young ſhoots, but the ſeedlings make the handſomeſt plants.

The ſeeds are procured in their cones from the ſeeds-men, and by expoſing them to a moderate heat, they readily open and diſcharge the ſeeds freely. The ſeaſon for ſowing them is any time in March, and they grow freely on a bed, or border of common light earth, eſpecially the firſt and third ſpecies. Let the ground be then dug, well broken, and raked ſmooth, then drawing an inch of earth evenly from off the ſurface into the alley, ſow the ſeeds moderately thick, and directly ſift the earth over them, half an inch deep. The ſeed being thus ſown, obſerve, that, if in April and May the weather proves warm and dry, a very moderate watering will be now and then neceſſary, and the plants will riſe in ſix or eight weeks; obſerving then, and during ſummer, to keep them clear from weeds, and in dry weather give them gentle waterings twice a week. In winter indulge them with occaſional ſhelter of mats in time of hard froſt. Thus continue your care till the ſecond ſpring after they come up, when they will be two years old; then in March or April tranſplant them from the ſeed-bed into a ſheltered ſituation, in nurſery rows two feet aſunder: and in three or four years they will be fit for the ſhrubbery, &c.

But if the ſeeds of theſe trees were ſown in pots, tubs, or boxes, and plunged in a moderate hot-bed, under occaſional ſhelter of mats, the plants will come up near a month ſooner than thoſe in the full ground; and they may be pricked out the following ſpring into the nurſery.

As

As the *Cupreſſus Thyoides*, however, is ſometimes a year after ſowing before the plants come up, it may therefore be proper to ſow the ſeeds in boxes, pots, or tubs, for the conveniency of removing them to the ſhade, to have only the morning ſun during ſummer, and to a ſheltered ſunny ſituation in winter; and if the plants ſhould not appear the firſt year, it would be of great advantage, in ſpring following, to plunge them in a hot-bed, as above obſerved; it will greatly forward the plants, ſo as to be fit to tranſplant the ſpring following.

*Propagation by Cuttinge.*

This may be tried upon all the ſorts, tho' as to the evergreen kinds, it is often two years before they are properly rooted. Chuſe the young ſhoots, plant them in October, in a ſheltered ſituation, and give plenty of water the following ſummer. But the plants raiſed from cuttings will not obtain more than half the ſtature of thoſe raiſed from ſeeds.

CUTTINGS. In gardening, Cuttings are a part of the branches of plants and trees, cut off and planted for the purpoſe of propagation.

Vaſt numbers of trees and plants may be increaſed by Cuttings; for, as a branch, or even the ſmalleſt twig of one, may be conſidered as a part ſimilar to the whole plant, and that when ſeparated, or cut from its parent, is devoid of a root, yet, being planted in earth, it in proceſs of vegetation forms one, as well as advances with a ſtem furniſhed with branches, and exhibits leaves, flowers, and fruit, exactly the ſame as the mother-plant, without the leaſt variation.

Some ſorts of plants are alſo propagated by Cuttings of their leaves, as in ſome ſorts of *agave* and *aloe*.

Numbers of trees grow ſo readily by cuttings, that it is the only expeditious method for raiſing them; as for example, the willow, poplar, and alder, which will grow either by ſmall Cuttings, of ſix inches or a foot long, or by large truncheons, a yard or more in length, and as thick as a man's wriſt. And of the willow, Cuttings of the large branches, two or three yards long, and two or three inches thick, planted in moiſt places, will readily grow.

But the proper parts of moſt other trees, ſhrubs, and herbaceous plants for cuttings, are principally the young ſhoots of one, or at moſt two years growth, though moſt trees and other plants ſucceed beſt by the one year's Cuttings, and planted in the autumn or ſpring after they are produced; and ſome ſorts of hard wooded plants ſucceed beſt by planting the ſame year's ſhoots in ſummer, as is obſerved under their reſpective articles.

The proper lengths to take off the ſhoots, as Cuttings, are various, from about three or four to twelve, fifteen, or eighteen inches long, according to the nature of the plant, length, ſize, and ſtrength of the ſhoots, of the reſpective ſorts; all of which is explained in the culture of all the different kinds that are propagated by this method, each under its reſpective genus.

In chuſing the Cuttings, always prefer ſhoots of the moſt robuſt growth, according to their nature, to the long, rambling, weakly ſhoots: prefer alſo thoſe that are freeſt from ſide ſhoots; and in taking off the Cuttings, that, if they are of the ſmaller, ligneous, ſhrubby plants, ſuch as the wall-flower, ſouthernwood, ſage, and the like, they may be ſlipped off with the hand from the ſide of the branch, though theſe are more properly ſlips than Cuttings. See SLIPS. And many of the ſmaller ſorts of ſhrubs, both deciduous and evergreens, may be taken off in the ſame manner; but thoſe of the ſtrong-ſhooting ſhrubs and trees, and all ſucculent plants, ſhould always be cut off, either from the ſide of a branch, or from the end of one, or the end of a former year's ſhoot, as is convenient. In taking off cuttings, it is often recommended to cut them with an inch or two of the former year's wood adhering to their bottom, particularly the vine, laurel, and ſeveral others, which may be practiſed where convenient; but moſt ſhoots that will grow by cuttings, ſucceed equally well without any of the old wood.

In preparing Cuttings previous to planting, trim off all ſide ſhoots; and all thoſe which have weak, tender, crooked, or ſtraggling tops, as often occur in many of the deciduous tribe, ſhould be topped, or ſhortened down to the firm ſtraight wood; though thoſe that have ſtraight robuſt tops, according to their nature, may remain entire, particularly the evergreen kinds, and never top any Cuttings of ſucculent plants.

Many ſorts of trees and ſhrubs that propagate by Cuttings, make very long one year's ſhoots, often long enough to admit of dividing into ſeveral lengths for cuttings of ten or fifteen inches each, as in the vine, honeyſuckle, jaſmine, paſſion-flower, with many other

deciduous climbers, and other trees; but I would obſerve, that the bottom part of theſe ſhoots that are firm and well ripened, cut off from about eight or ten to fifteen inches long, are the moſt eligible for Cuttings; though the upper parts, if they have ripened to a tolerably firm texture, may, in caſes of ſcarcity, be alſo uſed in lengths as above, rejecting the weak ſtraggling part toward the upper end; but the lowermoſt Cuttings generally make the beſt plants.

All Cuttings of trees, ſhrubs, and plants, that are not ſucculent, ſhould be planted as ſoon as poſſible after cut from the parent plant. But as to ſucculent Cuttings, they being moſtly very replete with moiſture, that when ſeparated from the parent, the moiſture continues to iſſue abundantly, often for ſeveral days at the cut part made in ſeparation, therefore, until that part is dried and cruſted over, it is not proper to plant them, otherwiſe the moiſture flowing out, would cauſe them to rot in the earth.

With reſpect to the mode of planting, moſt Cuttings of trees, ſhrubs, and all other plants, not ſucculents, ſhould be planted nearly two parts in three in the ground; but ſucculents ſhould be only juſt put as far into the earth as to make them ſtand, and is ſufficient to root; for if planted too low they are apt to rot, nor will they emit roots freely.

Some ſorts of Cuttings grow freely in the common open ground; others require a ſhady ſituation, and ſome to be potted for occaſional ſhelter; and others require the aid of a hot-bed, to promote their rooting, all of which is alſo fully exhibited accordingly, as the reſpective plants require, each under its proper genera.

Moſt ſorts of Cuttings will be ſufficiently rooted in one year, and ſome in one or two months, eſpecially thoſe ſorts planted in hot-beds, and even ſometimes in the full ground, when planted in the young wood in ſummer.

As to the ſeaſon for planting cuttings, ſpring and autumn is the time for moſt ſorts of trees and ſhrubs; and for herbaceous plants, ſuch in particular as grow by Cuttings of their flower-ſtalks, as the ſcarlet lychnis, lychnidea, &c. and ſuch as grow by young ſhoots from the bottom, as the carnation and pink, and thoſe ligneous-herbaceous plants that grow by young ſhoots from the ſides of the branches, as ſage, rue, roſemary, wall-flower, often ſucced beſt in ſummer, as ſoon as their ſhoots are of due ſize, in May or June, as is directed for each ſort in its proper place; but moſt ſucculents in particular ſucceed beſt by planting their Cuttings in ſummer, from about the middle of May till Auguſt, and they will be well rooted before winter.

All varieties of particular ſpecies of all ſorts of trees that grow by Cuttings, may, by that method of propagation, be continued diſtinct, the ſame as by grafting, budding, and laying; for the plant raiſed from a Cutting will be exactly the ſame as the parent, and can never vary like ſeedling varieties. See VARIETIES.

As there are numerous ſorts of trees and ſhrubs, both deciduous and evergreen, as well as many ſucculent and herbaceous plants, which grow by Cuttings, they will be particularly mentioned in their reſpective places in their proper genus, and the particular method of managing each kind, in reſpect to their propagation by Cuttings, fully explained.

**CYCLAMEN**, Sow-bread, but commonly called *Cyclamen*.

This genus conſiſts of many low, herbaceous, flowery perennials, of the tuberous-rooted tribe, conſiſting of a large, roundiſh, fleſhy root, crowned by numerous, angular, and heart-ſhaped, ſpotted, marbled leaves, and many fleſhy foot-ſtalks, ſix inches high, ſurmounted by monopetalous, five-parted, reflexed flowers.

Claſs and order, *Pentandria Monogynia*.

*Characters.*] CALIX is roundiſh, five-parted, and permanent. COROLLA is monopetalous, with a globular tube, the limb or upper part large, and divided into five ſpear-ſhaped reflexed ſegments. STAMINA, five filaments and ſtraight acute antheræ. PISTILLUM, a roundiſh germen, ſiliforme ſtyle, and acute ſtigma. PERICARPIUM, a globular unilocular berry, opening in five parts at top, and many oval angular ſeeds.

Modern botaniſts allow of but two ſpecies, one of which however admits of many beautiful varieties, and is the ſort principally known in our gardens.

The ſpecies is,

CYCLAMEN *Europæum*.

*European Cyclamen.*] Cyclamen, with a large orbicular or compreſſed fleſhy root, crowned by many angular and heart-ſhaped leaves, elevated about ſix inches on their own foot-ſtalks; and between them many fleſhy

fleſhy flower-ſtalks, of ſix or eight inches ſtature, terminated by reflexed flowers of different colours in the varieties, appearing in autumn, winter, and ſpring, ſucceeded by ripe ſeeds in June, July, and Auguſt.

Of this ſpecies are many varieties, all of the ſame habit of growth, ſize, and mode of flowering, only differing in the colours of the flowers, and time of appearing, and may be divided into three claſſes, the autumn, winter, and ſpring flowering, viz.

*Cyclamen Autumnale, or Autumnal Flowering.*

Common ivy-leaved autumnal white-flowered Cyclamen—ivy-leafed, autumnal, purple-flowered Cyclamen; both of theſe varieties having angular heart-ſhaped leaves, and which are generally marked with black in the middle, and the plants are very hardy —Round, heart-leaved, autumnal, purple Cyclamen; having large orbicular leaves, heart formed at the baſe, purpliſh underneath, and purple flowers with crimſon bottoms, and the plants are rather impatient of ſevere froſt, requiring either to be placed cloſe under a warm wall, or in pots, to move to occaſional ſhelter in winter. Of theſe varieties the two firſt are the hardieſt and the moſt common in the Engliſh gardens; all of them flowering in Auguſt, September, and October; the leaves riſing about the ſame time, and continue until May, then wither, and the ſeed bud lying cloſe to the ground all winter, ripens in June.

*Cyclamen Hyamale, or Winter Flowering.*

Orbicular, plane-leafed, Winter Cyclamen, with bright purple flowers—Angular-leafed, fleſh-coloured, Winter Cyclamen——white-flowered Winter Cyclamen.—All of which varieties flower towards Chriſtmas, continuing ſix weeks; and the leaves appearing at the ſame time, continue till ſummer, then decay, and the ſeeds ripen in July; the plants being rather a little tender, ſhould be planted on a warm border, and ſheltered from froſt, or ſome may be potted, to move to occaſional ſhelter.

*Cyclamen Vernum, or Spring Flowering.*

Heart leafed white Spring Cyclamen, having the upper ſide of the leaves veined and marbled with white, and white flowers with bright-purple bottoms—Angular, heart-leafed, purple, Spring Cyclamen, having the leaves veined and marbled with white, and purple flowers with crimſon bottoms—With marbled leaves and red flowers——Marbled leaves and entire white ſweet-ſcented flowers —With yellow flowers, but rare;——all of which varieties flower in March, April, and May, being furniſhed with leaves at the ſame time, which continue till the beginning of June, then decay, and the ſeeds ripen in Auguſt. This claſs of varieties are more tender than the two former; they, however, will often ſucceed planted cloſe under a warm wall, but it is alſo proper to have ſome in pots, to move to ſhelter of a green-houſe in winter.

The roots of all theſe plants are large, compreſſed, fleſhy lumps, emitting fibres at their baſe. The flowers and leaves of all the varieties ariſe immediately from the root, on their own proper foot-ſtalks, about from four to ſix or ſeven inches high, one flower generally crowns each ſtalk, each divided into five ſegments, reflexed backwards; and when the flowers fade, their ſtalks ſhrink ſpirally to the ground and envelope the ſeed-bud, and ſit cloſe to the earth among the leaves, increaſing to a large, round, baccaceous fruit; or ſeed-veſſel, ripening, as before obſerved, in June, July, or Auguſt.

All the varieties, though of humble ſtature, are very ornamental, both in their variegated large foliage, and their beautiful flowers, ſome of which are very fragrant; eſpecially of the vernal kind, which are alſo commonly the moſt beautiful; but all the ſorts merit admiſſion in every curious collection.

The two firſt autumnal varieties may be planted in any of the common borders; but all the other ſorts ſhould either be ſtationed cloſe under a warm wall, and ſheltered with mats, &c. in hard froſt, or potted and placed in a frame or green-houſe for the winter. They ſhould all have a dry light ſoil, otherwiſe the root is apt to rot by wet.

As the leaves of all the ſorts decay in May and June, that is the only proper period for removing the plants either for increaſe by dividing the root, or to plant them into freſh prepared earth, or to tranſplant them from one place to another, &c. but as the roots do not loſe their fibres, they ſhould not be often removed.

*Propagation, &c.*

All the ſorts are propagated by ſeeds, and the particular varieties by dividing their roots.

By ſeeds.—They grow freely in common earth, but it will be three, and ſometimes four or five years before ſome of the ſeedlings

will produce flowers; there is, however, this conſolation, that the flowers will be large and fine, and often ſome new varieties. Let the ſeeds therefore be ſowed ſoon after they are ripe, at leaſt, in Auguſt or September, in boxes, tubs, or large wide pots of rich light earth, and cover it half an inch deep; ſo place them to have only the morning ſun till October, then placed in a warm ſunny expoſure, and at the approach of bad weather remove them under a hot-bed frame, to have occaſional ſhelter of the lights, but expoſe them fully every mild day. By this care ſome of hardieſt ſorts will probably appear towards Chriſtmas, or before, but all of them in ſpring, obſerving in warm dry weather to give moderate waterings till their green leaves decay in ſummer; at which time place them to have only the morning ſun, as before, till October; then ſift half an inch of freſh earth over the ſurface, continuing to defend them from froſt in winter; and in ſummer following, when their leaves fade, tranſplant them where they are to remain, ſome in the full ground, and ſome of the tender kinds in pots, and in a year or two after ſome of them will begin to flower.

Bydividing the roots—They make but ſmall progreſs of increaſe by the root; however, the root may be divided by cutting it into two or three pieces, which muſt be done in ſummer, planting them again directly, and they will each flower at its reſpective ſeaſon.

CYDONIA, the Quince Tree. See PYRUS.

CYNARA, Artichoke and Cardoon.

Of this genus are two eminent ſpecies for the kitchen garden, the Artichoke and Cardoon, both hardy herbaceous plants; the former perennial, and the latter rather biennial, in England.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, compound flower, having a ventricoſe general calix, compoſed of numerous broad ſcales. COROLLA, numerous, tubular, hermaphrodite florets, each five parted at top. STAMINA, five capillary filaments, and cylindrical antheræ indented in five parts. PISTILLUM, an oval germen to each floret, ſlender ſtyle, and oblong emarginated ſtigma. PERICARPIUM, none.—SEMEN, a four-cornered ſeed, crowned with down, ſucceeds each floret.

Of the garden Artichoke there is but one real ſpecies, and of the Cardoon the ſame; but of the Artichoke there are two celebrated varieties.

The ſpecies of Artichoke is,

'CYNARA *Scolymus.*

*The Garden Artichoke,* formerly *Scolymus* ] Cynara, with large thick perennial roots, crowned by a conſiderable cluſter of large pennatifid erect leaves, two or three feet long, and in the midſt upright ſtalks a yard high, ſurmounted by a large, round, ſcaly head, being compoſed of numerous, oval, calycinal ſcales, encloſing the florets, ſitting on a broad, fleſhy receptacle, which, as well as the fleſhy baſe of the ſcales, is the only eatable parts of the plant.

*Varieties of this are,*

*Conical-headed green French Artichoke*—— having the folioles of the leaves commonly terminated by ſmall ſpines, a tall ſtalk, the head ſomewhat conical, and of a light green colour, and with the ſcales pointed at top, opening and turning outward.

*Globular-headed red Dutch Artichoke*—having leaves without ſpines, a ſtrong ſtalk, the head large, globular, a little compreſſed at top, and of a reddiſh-green colour, broad obtuſe ſcales emarginated at top, growing cloſe, and turn inward.

Of theſe two varieties the globular-headed kind is deſervedly in moſt eſteem, being conſiderably larger than the conical-headed Artichoke; and its eatable parts, both of the bottom and ſcales, are conſiderably more thick and fleſhy, as well as more agreeably flavoured, and ſhould therefore be principally cultivated both for family and market.

Both the varieties are perennial in root; but the leaves and fruit-ſtem die to the ground in winter, and their roots remaining, ſend up new leaves, and a ſupply of Artichokes every ſummer, for ten or twenty years, if required. The conical green headed ſort is rather the hardieſt to reſiſt the power of ſevere froſt.

The flowers and ſeed of all the plants of this genus are produced in the centre of the head, the ſcales of which are the proper calix of the flower, which conſiſts of numerous ſmall bluiſh florets, ſucceeded by downy ſeeds, ſitting naked on the receptacle.

*The Culture; and firſt of their Propagation, and Method of planting.*

Both the varieties of Artichoke are propagated always by ſlips or ſuckers, ariſing annually from the ſtool or root of the old plants in

in ſpring, which are to be taken from good plants of any preſent plantation, in March or beginning of April, and planted in the open quarter of the kitchen-garden, in rows five feet aſunder, all as hereafter directed, and they will produce Artichokes the ſame year in autumn, the ſame plants enduring many years, and produce a freſh crop annually in ſummer.

It however ſhould be remarked, that although Artichokes are of many years duration, yet, their annual produce of fruit will, after the third or fourth year, be every ſeaſon ſmaller, and leſs fleſhy in the eatable parts; ſo that a freſh plantation ſhould be made every three or four years: but, in order to obtain a longer ſucceſſion of heads during each ſeaſon, I ſhould adviſe to make a freſh plantation annually, whereby you will have a regular ſupply of fruit ſeveral months, i. e. from June till November; for the old plants of one or more year's ſtanding produce their heads in June and July, and are moſtly over by Auguſt; at which time, the young plantation of the ſame year takes place, producing fine large heads, continuing to come in gradually till November: therefore, by planting a few every ſpring, that beſides the long ſucceſſion of fruit, you have always a crop ready to ſucceed the old ones, when you ſhall think proper to eradicate them; which, when intended, may be done in autumn, after they have yielded their ſummer crop; at which time, obſerving, that if you ſhall have occaſion for many young plants as ſoon as poſſible in ſpring, ſome of the beſt of theſe old ſtools may, in October or November, be trenched in cloſe together, in ſome dry warm place, under a hedge, or any fence open to the full ſun, raiſing the earth up about the young ſhoots; and in winter, when hard froſts prevail, cover with long dung litter, and thereby you will have a chance of obtaining good plants for a new plantation, if the ſeverity of the winter ſhould deſtroy or much injure thoſe in the open quarter; and even at any rate, they will furniſh young plants ſooner by a fortnight or a month, than the ſtanding crops in an open expoſure, eſpecially if the winter has proved ſevere; ſo after having ſlipped off the beſt young ſhoots for planting, eradicate the old roots entirely.

The ſlips, ſuckers, or young plants, either of any ſtanding plantation, or of the old roots above-mentioned, are generally to be taken off for planting in March, and ſometimes in very backward ſeaſons, or after hard winters, it will be the beginning or middle of April, before they are large enough for that purpoſe, which ſhould be from about eight or ten inches to a foot long. For the method of ſlipping or taking them off for planting, ſee the method *Of their Spring Dreſſing*.

With reſpect to ſituation and ſoil for theſe plants, they ſhould have a free expoſure; the more diſtant from ſpreading trees the better, which would draw them up weak; and as to ſoil, they proſper in any common ſoil of a kitchen-garden, capable of producing tolerable crops of other eſculent plants, though they are the moſt proſperous in a ſomewhat moiſt ſoil; but, if poſſible, avoid planting them in wet ground, as in ſuch the plants would be in danger of rotting, or ſubject to great injury in winter; and having fixed on the ground, lay thereon a conſiderable coat of rotten dung, ſpreading it equally over every part; then trench the ground one good ſpade deep, beſides the top paring or ſhovelling, and each trench two ſpades wide, as you proceed, bury the dung equally in the bottom of the trenches.

The ground being thus prepared, then get the plants, ſuch as above-mentioned, and prepare them for planting; obſerving to make choice of ſuch of the ſhoots or ſuckers only that are beſt furniſhed with ſome fibres to their root; taking theſe one by one, cut off the hard knobbed part at bottom, rejecting ſuch that are very tough and ſtringy, and trim the outer leaves down about one third or near half way, ſo as the central ones have full liberty to expand. Being thus trimmed, let them be directly planted by line and dibble, in rows five feet aſunder, and the plants two feet diſtance in each row, putting each plant three or four inches deep in the ground, cloſing the earth well about the root and body of the plant as you proceed in planting; and immediately let every one be watered, for this will ſettle the mold cloſe about them, fix every one firmly in its place, and promote their early rooting; obſerving, if the weather at this time proves dry, to repeat the waterings every three days, for a week or a fortnight, till they have taken freſh root, and begin to grow.

After this, they require no further culture during ſummer than to be kept clean from weeds, which is readily done by hoeing with a large hoe between the plants in dry weather.—And in the beginning of winter

winter the ground muſt be ridged up along each row, to defend the plants from froſt.

In making plantations of Artichokes, that if it is neceſſary to make the moſt of every piece of ground, as is conſequently the caſe with the market gardeners, you may ſow between the rows a crop of round-leafed ſpinach, with ſome ſhort-topped radiſh, and a ſprinkling of coſs lettuce, mixing the ſeeds together, and ſow them by broad-caſt; then tread in the ſeed and rake the ground, for the Artichokes will ſoon get the ſtart out of the way of theſe ſmall crops, and when they come off in June, may plant a row of cabbage or ſavoys along the middle of each ſpace between the Artichoke ranges, to come in for autumn ſervice.

But the kitchen-gardeners in the neighbourhood of London frequently plant their Artichokes at ſuch diſtance between the rows, as to have ſpinach, radiſhes, cauliflowers, pickling-cucumbers, and cabbage or ſavoys, all from the ſame ſpot. To do this, they allow ten feet between the rows of Artichokes, ſowing the ground, as above, with ſpinach, radiſhes, &c. in ſpring; and at the ſame time plant in each ſpace two rows of cauliflowers, at four feet diſtance, and two and a half apart in each row; and then, in the firſt week of June, when the ground is cleared from the radiſhes and ſpinach, they ſow cucumbers for pickling between the cauliflower rows, and in June or July plant, in the intervals between the rows of Artichokes and cauliflowers, a row of cabbage or ſavoys; the cauliflowers coming off in July or early in Auguſt, there will be full ſcope for the remaining crops; and the cabbage and ſavoys coming in for autumn uſe, will be all gathered by the middle or end of November, time enough for landing up the Artichokes.

*Their Culture when in Fruit.*

The plants of the new plantation will begin to ſhew their fruit or heads the beginning of Auguſt, and will be in the fulleſt perfection from about the middle of that month to the latter end of September; and ſometimes they continue fruiting gradually until November; but next year the ſame crop will come into fruit in June and July, and be moſtly all over in Auguſt; ſo that, as already noticed, if you would continne a ſucceſſion annually from June to November, always plant a few every ſpring, to come into fruit to ſucceed thoſe of older plants.

But with reſpect to the care of the plants when in fruit, obſerve, that, beſides the principal or top fruit, ſeveral collateral ſmall heads often ariſe from the ſides of the main ſtem, which ſide-ſhoots, or ſuckers, being diſplaced, the whole nouriſhment is conſequently directed to the principal head; therefore if you prefer one large handſome head to three or four ſmall ones, the above culture ſhould be conſtantly practiſed, from time to time, before the ſide heads exceed the ſize of a hen's egg.

Theſe ſmall ſide-heads or ſuckers are by many greatly eſteemed, being cooked in various ways, and ſerved up to table; and the London gardeners having great demand for them, they gather them as they are produced, and tye them in bunches for market.

But ſome perſons, not anxious about having very large heads, ſuffer the above-mentioned ſide-ſhoots to remain, rather preferring three or four middling ones, from the ſame ſtem, in ſucceſſive order, than only one large fruit.

The maturity of the Artichoke heads, is, when arrived to their full magnitude, diſcoverable by the ſcales diverging from each other conſiderably, but before the centre or crown opens, to ſhew an effort for flowering.

When the heads are to be gathered, you ſhould cut them with ſix or eight inches of the ſtalk at leaſt; but if for market, almoſt three times that length.

But as the heads are gathered, the whole ſtalk ſhould always be broken down cloſe to the ground, being abſolutely neceſſary to the welfare of the plants, by encouraging their ſtools to produce ſome new ſhoots more freely before winter.

In Covent-Garden and the other London markets, Artichokes are ſold commonly from about two to three ſhillings per dozen, and ſometimes at a little more or leſs, according to the kinds and ſize; but the globe kind is always the moſt ſaleable.

*Their Winter Dreſſing, and landing up, to protect them from Froſt.*

The winter culture of Artichokes is principally to land or earth up the rows, to guard the crown of the root and young ſhoots from ſevere froſt, which is done by digging the ground, and forming the earth into a ridge along each row over the roots, without which precaution, the inclemency of the winter

winter often proves deſtructive to thoſe plants.

This work ſhould be done towards the latter end of November, or beginning or middle of December, according as the weather continues more or leſs mild.

In the firſt place, cut down all the large leaves near the ground, preſerving only thoſe of the ſmall young ſhoots; and this may be done any time in November; then at the time above-mentioned, proceed to dig the ground between the rows, and work it up cloſe to the plants, in a ſort of ridge, along each row. But the moſt regular way is, that if the plants are in cloſe rows for a full crop, i. e. in rows five feet aſunder, range a line exactly along the middle of each ſpace between the rows, then with the ſpade chop the ground along according to the line; and thus you form beds five feet broad, one row of plants ranging along the middle of each bed; then dig the ground bed and bed a moderate ſpade deep, gradually working the earth from each ſide towards the middle in a ridge along the row of plants, as above obſerved, ſo as each row ſtand exactly in the middle of every ſuch ridge of earth; rearing the earth cloſe about the plants, but not quite over their tops; and this will greatly ſhield the crown of the root and young ſhoots from the effects of hard froſts.

But when the rows of Artichokes are ten feet diſtant, as in many of the kitchen-gardens, for the ſake of obtaining other crops between, you may then either ridge up the plants, in five-feet wide beds, as above directed, or trench all the ground in the common way, in ridges two or three feet wide, ranging the way of the rows, and digging them one ſpade deep; and as you advance to each row of plants, land them up, by forming a good ridge along the row, that each row ſtand in the middle of a ridge of earth, as in the other method.

Some perſons, however, inſtead of landing up the plants in either of the above methods, only draw a little earth, with a hoe or ſpade, up cloſe about the plants, and at the approach of ſevere froſt, add a covering of long dung litter, or ſome ſuch like light material; and ſome never land, nor draw any earth about them at all, only mulch the plants in December, or towards Chriſtmas, or ſooner, if hard froſts ſet in, laying ſome ſhortiſh dry mulch about each hole of plants, bringing it cloſe around about the ſhoots, and let it remain all winter, till danger is paſt; either of which methods is indeed often ſufficient in our ordinary winters; but as there is no knowing what weather will happen, ſo it is not always to be depended on; and there is nothing ſo effectual for the benefit of the plants, as ridging up the earth about them, as before directed.

Remember, however, that if the froſt in winter ſhould prove extremely ſevere, it is alſo adviſeable to lay over each ridge a covering of any kind of long dry litter, which, together with the ridge of earth, will effectually ſecure the plants.

Likewiſe obſerve, that if hard froſts ſet in before you have time to land the plants, do not fail, in that caſe, to lay a thick covering of dry litter over them.

All coverings that have been occaſionally uſed during hard froſt, ſhould be removed in February, or at leaſt as ſoon as the weather breaks; and in March or beginning of April the ridges of earth ſhould be levelled down, and the plants have their ſpring dreſſing as follows.

*Their Spring Dreſſing, by levelling down the Ridges, and diſplacing the ſuperabundant Shoots.*

In March or beginning of April, according to the forwardneſs of the ſeaſon, that the plants have made ſome tolerable ſhoots, the ridges of earth landed over them in winter for their protection, ſhould be levelled down, and all ſuperabundant and ill placed ſhoots cleared away, leaving only two or three of the moſt promiſing ſuckers upon each ſtool.

Taking opportunity of dry weather for this work, dig or level down the ridges of earth length-ways, row and row, ſtirring all the ground between and cloſe about the plants; and as you proceed, remove the earth from about the crown of the root and young ſhoots, as low as the part of the ſtock from whence they ariſe; then, if there are ſeveral ſhoots, fix upon two or three of the ſtraighteſt, moſt promiſing, and beſt ſituated on each root, toward the lower part of the ſtool, at ſome diſtance from each other; let all the reſt be cleared away, by ſlipping them off cloſe to the root, and directly draw in the earth again about the remaining ſhoots, cloſing the earth well around them, and preſs it gently between, to preſerve them as far diſtant from each other as their ſituation will admit, and trim off any broken or dangling leaves; and in this manner

manner treat every ſtock, as you advance in digging or laying down the ridges, obſerving to level the ground in a neat manner; and if you chuſe, the ſpaces between the rows may be ſown with ſpinach, &c. or any light crop, as obſerved at the time of making the plantation.

But I would remark of this ſpring dreſſing, that if in March you find the ſtocks ſhoot weakly, occaſioned by hard froſt or much wet, it will be proper, only for the preſent, to open and looſen the earth, and level down the ridges a little, to encourage the roots; and in three or four weeks after, when they have made tolerable ſhoots, may ſlip them as above, and dig and level the ground properly.

The young ſhoots which are ſlipped off in the above ſpring dreſſing, are, as before obſerved, the proper plants wherewith to make new plantations; a proper quantity of the beſt ſhould therefore be reſerved, making choice of ſuch that are ſtraight, from about eight or nine inches to a foot long, and whoſe bottoms cut free and criſp, rejecting ſuch that are very tough and woody at the baſe.

The ſooner they are planted after being ſeparated from the old plants the better; but if the ground ſhould not be ready, lay them till then, by the roots in a trench, placing them upright, for if placed ſlanting they, by aſſuming an upright growth, would become crooked.

If theſe plants are to be purchaſed, the true globe ſort is ſold at eight or ten ſhillings a hundred, and ſometimes a guinea, or more, after a hard winter.

When they are to be conveyed to any conſiderable diſtance, they ſhould be packed dry, in ſmall bundles of eight or ten, wrapping dry hay about them, and tying each bundle with a hay band, and pack the ſeveral bundles in hampers or large garden-mats; when they arrive, place the roots in water a few hours previous to planting.

*Of manuring the Plants.*

Such plantations of Artichokes which are permitted to remain ſeveral years in the ſame place ought to have the ground manured every other year, with ſome thoroughly rotten dung, applying it in November, at the time of landing up the plants, and dig it in one good ſpade deep.

By this practice a plantation of Artichokes will continue in good condition, and bear tolerable heads for ſeveral years; though as they grow old, the heads will be ſmaller in proportion.

*Second Species of Cynara, the Cardoon.*

The Cardoon, in its general habit, greatly reſembles the Artichoke plant, but is of larger and more regular growth; the leaves more upright, taller, broader, and more deep and regularly divided; and the ſtalks of the leaves, blanched, are the only eatable parts of the plant.

There is but one ſpecies, viz.

CYNARA *Cardunculus.*

*Cardunculus or Cardoon.*] Cynara, with thick, fleſhy, fibrey roots, crowned by a conſiderable cluſter of large, erect, deeply-pinnatifid leaves, four or five feet high, having all the lobes pinnatifid and thick prickly foot-ſtalks; and amidſt them, upright tall ſtems, terminated by ſcaly, Artichoke like heads, furniſhing flowers and ſeed. It is a hardy plant, and proſpers in the open quarters of the kitchen-garden.

This plant is often biennial in England, ariſing from ſeed in ſpring, obtains perfection in autumn and winter, ſhoots up ſtems in ſpring after, flowers in July, ripens ſeed in September, and the whole often dies the winter following in this country; but it rarely produces good ſeed here, ſo it is commonly procured by the ſeedſmen from France, Spain, and Portugal. The plant is large, regular, and of noble appearance in its general growth.

The ſtalks of the leaves being thick, criſp, and palatable, are the eatable parts, firſt blanching them like celery about a yard or more long, to render them white, tender, and agreeably flavoured, which otherwiſe would be rank and bitter; they are in perfection in autumn and winter, and are uſed for ſallads, ſoups, ſtewing, and other culinary purpoſes.

It is but of little eſtimation at preſent in England, nor is it much cultivated now by the market gardeners; it requiring ſo much room to grow, and there being but little demand for them, they often do not pay for the culture, though they ſell for five ſhillings or three half crowns a bunch, and only three plants in each.

A few of them, however, for variety, merit a place in every conſiderable kitchen-garden, both for uſe and market.

The

The plants being of conſiderable growth, require to grow in rows five feet aſunder, and four diſtant in the rows.

*Propagation and Culture.*

It is propagated by ſeed ſowed annually in the full ground in March, either in a bed for tranſplantation, or at once in the place where you deſign the plants ſhall ſtand to come to perfection. Moſt authors direct the former method, though ſome of them, ſeemingly, neither ſaw nor practiſed any, nor perhaps ever ſaw the plants; we, however, have practiſed both ways, and have experienced, that holeing in the ſeeds where the plants are to remain, is the moſt ſucceſsful culture, and is the method I have alſo lately obſerved practiſed in ſome of the moſt eminent kitchen-gardens in the vicinity of London; for the plants being rather of rampant growth, and very flaggy on removal in dry or hot weather, they do not ſucceed ſo well by that method, as when they always remain in the ſame place, in which they grow faſter, ſtronger, and ſooner arrive at a proper ſtate of growth for blanching.

But we ſhall exhibit the practical directions for both methods of culture.

Firſt by tranſplantation.—Sow the ſeed in March, or beginning of April, by broad-caſt, in a bed of rich earth, tread it in, and rake the ground, and when the plants are three inches high, thin them to four or five inches diſtance, that they may not draw each other weak; and in June they will be fit to tranſplant: in the beginning or middle of June, therefore, prepare an open ſpace of ground that has been dunged in the preceding winter or ſpring; and there draw lines five feet diſtance, and put in the plants by dibble, at four feet diſtance in the lines, either on level ground, or hole them, in wide baſon like holes, eighteen inches over, and ſix or eight deep, making the ſides ſloping, ſo looſening the bottom well, and ſet one good plant upright in each hole; give water directly, which repeat, if dry weather, every evening or morning till they have taken root; after this, all they require is hoeing the ground occaſionally to kill weeds, until the end of September or October, when the plants will be arrived nearly at full growth, ſo as the leaves of the different plants will almoſt meet, and thoſe of each plant are then to be tied together, and landed up to blanch them, as hereafter directed.

By ſowing where they are to remain.—Let the ground be marked out in lines five feet diſtance, as in the tranſplanting method, then along each line form baſon-ſhaped holes, eighteen inches wide, and about three deep, the holes four feet from centre to centre; in each hole drill in three ſeeds, ranging the way of the row, covering them half an inch deep; give occaſional waterings in very dry weather; and when the plants are come up three or four inches high, thin them to one of the ſtrongeſt in each hole; at the ſame time clear away weeds, and ſtir the earth with a hoe about each remaining plant; and thus they will grow more freely and ſtronger than thoſe which are tranſplanted, and ſooner arrive to full ſize, with large ſtalks, in fine order for general blanching.

Theſe plants are cultivated in wide rows, on account of their large growth, as well as for the convenience of having a ſufficient portion of earth to land them to a due height, i. e. two or three feet at leaſt; but in rich ground they often grow four feet high, and it is neceſſary to land them up, for blanching, almoſt their full length.

All the culture neceſſary for theſe plants during their growth till fit for blanching is, to keep them clean from weeds, by hoeing the ground.

As theſe plants ſtand at conſiderable diſtances from each other, you may have ſome ſmall temporary crops between the rows the firſt three months, ſuch as ſpinach, lettuce, endive, cabbage, ſavoy, or broccoli plants, for tranſplanting, &c. obſerving to keep the holes of Cardoons perfectly clear from every thing.

*Method of landing them for blanching.*

In the latter end of September, or in October, the Cardoons will be grown very large, and their foot-ſtalks have acquired a thick ſubſtance, you muſt then tye up the leaves of each plant, to admit of landing them up cloſely all around, for blanching, which will be ſix or eight weeks in effecting, and the plants will come in for uſe in November and December, and continue all winter.

But if the plants are required for uſe as ſoon as poſſible in autumn, the blanching may be begun in Auguſt, ſo as to have the plants for uſe towards the latter end of September and October; but by tying up, and landing the plants before they are full grown, they never acquire a due ſubſtance in the ſtalk, and the excellence of a Cardoon is, to have

the ſtalks (the eatable part) broad and thick.

The method is, firſt, having hoed and cleared the ground from weeds, then, having procured ſome hay-bands an inch and a half thick, proceed with theſe materials, on a dry day, to tye up the leaves of each plant moderately cloſe, and regularly together, winding the hay-band cloſely around the plant almoſt to its top; this done dig the earth, and as you proceed, bank it up cloſe round each plant nearly as high as the tying or bandage, ſmoothing it with the back of the ſpade, both to fix it properly, and that it may readily ſhoot off the wet; obſerving, if the plants ſhould advance more in height, to continue the tying of hay-bands higher in proportion; for it is neceſſary to have them tyed up nearly their full height, both to blanch them more effectually, and ſecure them from injury of wet and froſt.

To obtain a more regular ſucceſſion, the landing may be performed only to about one third of the plants at a time, allowing the diſtance of a fortnight between each time of landing.

In ſix or ſeven weeks the plants are ſometimes tolerably blanched, but in two months or ten weeks, they are generally in excellent order.

They may be continued all winter, with the care of covering the tops of the plants with long litter during hard froſts.

To ſave Cardoon ſeeds.—Cultivate a few plants in a ſheltered ſunny place; let them ſtand unblanched, protecting them from froſt with light litter; they will ſhoot up in ſpring following, flower in July, and if a fine warm dry autumn, they will ripen ſeed towards Michaelmas.

CYNOGLOSSUM, Hound's Tongue.

It furniſhes hardy herbaceous biennials, perennials, and annuals, for medical uſe, and as flowering plants for ornament in gardens.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is oblong, five-parted, and permanent. COROLLA is monopetalous, funnel-ſhaped, five-parted at the brim, and the chaps cloſed. STAMINA, five filaments, and roundiſh antheræ. PISTILLUM, four germen, permanent ſtyle, and indented ſtigma. PERICARPIUM none, but four ovilli, having four ſeeds.

The material ſpecies are,

[1]CYNOGLOSSUM *Officinale.*

*Officinal, or Common biennial Hound's Tongue.*] Cynogloſſum, with large, thick, blackiſh roots, crowned by large, oval, ſpear-ſhaped, hoary leaves, and amidſt them, upright firm ſtalks two feet high, adorned with narrow cloſe-ſitting leaves, and terminated by reddiſh flowers, in June and July.

*Varieties.*] White flowering Hound's Tongue—Evergreen Hound's Tongue.

This ſpecies and varieties may be conſidered both as biennials and perennials, becauſe in moiſt ſoils they often die ſoon after they have perfected ſeeds; but in dry gravelly ſoils, the roots are often of ſeveral years duration.

It grows wild under hedges, and is chiefly valued for its root in medicine.

[2]CYNOGLOSSUM *Omphalodes.*

*Omphalodes, or perennial, creeping, Venus Navel Wort.*] Cynogloſſum, with ſlender trailing ſtalks, creeping and rooting at every joint, heart-ſhaped ſmooth leaves, on long foot-ſtalks; and from the axillas of the ſtalks, bright blue flowers in looſe panicles, appearing in March, April, and May.

[3]CYNOGLOSSUM *Linifolium.*

*Flax-leaved Annual Hound's Tongue, or Common Venus Navel-Wort.*] Cynogloſſum, with upright, ſlender, branchy ſtalks, ſix or eight inches high, garniſhed with long, very narrow, ſmooth, greyiſh leaves; and all the branches terminated by looſe panicles of ſmall white flowers, in June and July.

[4]CYNOGLOSSUM *Luſitanica.*

*Portugal Annual Hound's Tongue, or Taller Venus Navel-Wort.*] Cynogloſſum, with upright branchy ſtalks ten or fifteen inches high, garniſhed with ſpear ſhaped rough leaves, and all the branches terminated by looſe ſpikes of white flowers, in June and July.

The flowers of all theſe plants are ſingly, of one funnel-ſhaped petal, are ſmall but pretty numerous, which in the firſt, third, and fourth ſorts, are ſucceeded by plenty of ſeeds.

Of theſe four ſpecies, the ſecond, third, and fourth ſorts, are thoſe that merit culture as flowering plants, and are pretty ornaments for the fronts of borders, &c. the two latter of which have been long inhabitants of our gardens, in the collection of hardy annuals.

They are all hardy, and proſper in the open borders.

*Propagation.*

The firſt ſpecies may be raiſed by ſowing the ſeed in any ſoil in autumn or ſpring,

and they will riſe plentifully in March or April.

The ſecond ſpecies propagates itſelf abundantly by its rooting ſtalks, cuttings of which may be taken off with roots, in ſpring, ſummer, or autumn, and planted where they are to remain.

The two annual ſorts are always raiſed from ſeed in ſpring, ſown in patches in the borders where they are to flower, ſowing ſeveral ſeeds in each patch a quarter of an inch deep; and when the plants come up, occaſional water and weeding is all they require, and by two or three different ſowings, they will flower from June till the end of ſummer.

CYPRIPEDIUM, Ladies Slipper.

It conſiſts of two ſpecies of hardy herbaceous perennials for ornament, growing erect about a foot high, garniſhed with large oval leaves, and crowned by large, quadripetalous, nectarious flowers.

Claſs and order, *Gynandria Diandria.*

*Characters.*] CALIX is a ſpatha. COROLLA, four or five long, ſpear-ſhaped, expanded, erect petals, and in the midſt a large, ſwollen, roundiſh, hollow nectarium. STAMINA, two ſhort gynandrous filaments, and erect antheræ. PISTILLUM, a long contorted germen, ſhort ſtyle, and obſolete ſtigma. PERICARPIUM, an oval, trigonous, three-furrowed, unilocular capſule, and numerous ſeeds.

The ſpecies are,

[1]CYPRIPEDIUM *Calceolus.*

*Calceolus Maria, or Common Ladies Slipper.*] Cypripedium, with thick, fleſhy, fibrous, creeping roots, ſending up, in ſpring, ſeveral upright robuſt ſtalks a foot high, adorned with large, oval, ſpear-ſhaped, ribbed, cloſe-ſitting leaves, placed alternate, and ſurmounted by a ſpatha, protruding a large flower, expanding its four petals cruciforme, having in the centre a large hollow nectarium; the whole very elegant, and of different colours in the varieties.

*Varieties are*] Common Ladies Slipper, with deep-purple flowers——Pale-purple flowers—Golden flowers—Red flowers——Large yellow flowers—With variable flowers.

This ſpecies and reſpective varieties are perennial in root, but the ſtalks and leaves riſe annually in ſpring, and decay in autumn, and all the ſorts flower in June; are extremely ornamental, and their ſtructure ſingularly curious, particularly in their large roundiſh nectarium, which is feigned to reſemble a ſlipper; hence the plants derived the name.

It grows wild in ſome ſhady woods in Britain, but it nevertheleſs highly merits culture in every eminent garden, both as a plant of curioſity and ornament.

[2]CYPRIPEDIUM *Bulboſum.*

*Bulbous Ladies Slipper.*] Cypripedium, with a roundiſh bulbous root, crowned by radical roundiſh leaves; and between them erect low ſtalks, terminated each by one large flower, having an oblong nectarium.

Both the ſpecies, &c. are perennial in root, but annual in ſtalk and leaves.

The flowers of all the ſorts appear the end of May or in June, all of them compoſed of four or five large expanded petals, and a very conſpicuous nectarium in the centre; ſucceeded by ripe ſeeds in Auguſt, and they ſoon after decay to the roots.

They are very hardy, and delight in a ſomewhat moiſt undunged ſoil, open only to the morning ſun. They ſucceed either in the full ground or in pots.

*Propagation, &c.*

The firſt ſort and varieties, having knotty, fibrey, creeping roots, may be propagated by dividing or taking off joints in autumn, as ſoon as the ſtalks decay.

The bulbous ſort is alſo increaſed by the roots when the ſtalks decay.

Both the ſpecies may alſo be raiſed from ſeed, ſown in autumn in a ſhady border, and the plants will flower the ſecond or third year; eſpecially if ſuffered to ſtand where they were ſowed.

Theſe plants ſhould not be often removed, which would retard their flowering.

CYTISUS, Tree Trefoil.

This genera furniſhes ſome elegant flowering ſhrubs and evergreens, of hardy growth, for the pleaſure ground, adorned with oval leaves by threes, and long ſpikes of yellow papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is bell-ſhaped, ſhort, and divided into two lips, the upper one bifid, and the under one three-parted. COROLLA is papilionaceous; the ſtandard oval, riſing, and reflexed on the ſides; the wings obtuſe, and the length of the ſtandard, and the keel bellied and acute. STAMINA, ten diadelphous filaments, and ſimple antheræ. PISTILLUM, an oblong germen, ſimple ſtyle, and obtuſe ſtigma. PERICARPIUM, an

oblong blunt pod, narrow at the baſe, and kidney-ſhaped ſeeds.

There are about five ſpecies of *Cytiſus* in the Engliſh gardens, three of them deciduous ſhrubs, and one or two evergreens.

The ſpecies of our gardens are,

[1]CYTISUS *Laburnum.*

*The Laburnum, or Large Deciduous Cytiſus.*] Cytiſus, with a large upright tree-ſtem, branching into a full-ſpreading head, twenty or thirty feet high, having ſmooth greeniſh branches, oblong-oval entire leaves, by threes, on long ſlender foot-ſtalks; and from the ſides of all the branches, numerous yellow flowers collected in long ſpikes, hanging looſely downward, appearing in May.

*Varieties of this are*] Common broad-leafed Laburnum—Narrow-leafed, long ſpiked Laburnum, having very long pendulous ſpikes of flowers—Short-ſpiked Laburnum, having ſhort, roundiſh, thick ſpikes of flowers—Variegated-leaved Laburnum. The firſt two of which varieties are tolerably permanent from ſeed, but the other two muſt be continued by cuttings.

All theſe varieties are deciduous, but their leaves appear early in ſummer, which, together with their numerous, long, pendulant ſpikes hanging from every part of the branches, appear very ornamental, and are well adapted to place on the borders of woods, wilderneſſes, and large ſhrubbery plantations, on the boundaries of lawns, parks, &c.—And, although they are generally conſidered only as ornamental ſhrubs, if encouraged by training them to a ſtem at firſt, and ſuffered to ſtand, they will form moderate-ſize timber-trees: they grow naturally on the Alps, the mountains of Dauphiné, and in the Highlands of Scotland; and the timber being very hard, and taking a fine poliſh, is frequently uſed for making chairs, tables, bedſteads, and other furniture, which are ſaid to equal the fineſt mahogany in beauty.

The trees are ſo very hardy, that they will proſper any where, and are of very quick growth.

[2]UYTISUS *Seſſilifolius.*

*Seſſil-leaved Diciduous Cytiſus, often called Cytiſus Secundus Cluſii.*] Cytiſus, with a low ſhrubby ſtem, branching into numerous, erect, browniſh branches, forming a buſhy head five or ſix feet high, garniſhed with ſmall oval leaves by threes, ſome on very ſhort foot-ſtalks, others ſitting cloſe, and bright yellow flowers in ſhort erect ſpikes at the ends of the branches, appearing in June.

[3]CYTISUS *Nigricans.*

*Black Cytiſus.*] Cytiſus, with a ſhort ſhrubby ſtem, dividing low into many erect ſlender branches, forming a buſhy head four or five feet high, oblong-oval, dark-green, triſoliate leaves, and yellow flowers, terminating all the branches in upright ſpikes, appearing in July.

[4]CYTISUS *Hirſutus.*

*Hairy Evergreen Neapolitan Cytiſus.*] Cytiſus, with an upright, ſhrubby, grey ſtem, ſending out many erect, greeniſh, hairy branches, forming a fine head ſix or eight feet high, cloſely garniſhed with ſmall, oval, hairy folioles by threes, on ſhort foot-ſtalks, and yellow flowers from the ſides of the branches in ſhort pendulous ſpikes, having trifid hairy cups, appearing in June.

This ſpecies being rather impatient of very ſevere froſt, ſhould have a dry ſoil, and ſheltered ſituation in the ſhrubbery.

[5]CYTISUS *Auſtriacus.*

*Auſtrian, or Tartarian Evergreen Cytiſus.*] Cytiſus, with a ſhrubby ſtem, dividing low into many greeniſh branches, forming a buſhy head three or four feet high, cloſely garniſhed with oblong-oval, ſmooth, whitiſh-green leaves, and bright yellow flowers, in cloſe umbellate heads at the ends of the branches, having a cluſter of leaves under each head; appearing in May.

*Variety.*] Auſtrian,—Siberian Cytiſus, with ſmaller leaves, naked flower-ſtalks, and ſmaller flowers.

Theſe five ſpecies have univerſally trifoliate leaves, i. e. three folioles on each foot-ſtalk.

The flowers of all the ſorts are papilionaceous, or butterfly-ſhaped, conſiſting of the ſtandard, two wings, and the keel; all of them flower abundantly in this country, and are ſucceeded by oblong pods, containing plenty of ripe ſeed in autumn.

All theſe ſhrubs have great merit in ornamental plantations, either to aſſiſt in forming clumps or continued ſhrubberies; their numerous trifoliate leaves being finely adapted for effecting variety in aſſemblage, and during their bloom, they appear covered with flowers.

The large ſorts, ſuch as the ſeveral varieties of *Laburnum*, ſhould be ſtationed rather backward in clumps, and other ſhrubbery works; and the other four ſpecies ſhould occupy

cupy places more towards the front, and in the moſt conſpicuous departments.

They ſhould all be ſuffered to retain their natural growth, except only cutting off any very irregular ſhoot or branch.

All the ſorts are hardy, and will proſper in any common ſoil and expoſure; though, as the *Cytiſus Hirſutus* is ſometimes affected by ſevere froſt, it ſhould have a dry ſoil, and ſomewhat ſheltered ſituation.

*Propagation.*

All the ſorts are raiſed plentifully by ſeed, and ſome ſorts by cuttings.

By ſeed.—The ſeed grows freely in the full ground, and ſhould be ſown in March, in four-feet beds, either drilling it in, half an inch deep, or ſow it on the ſurface, and cover it that depth with earth; they will come up in ſix or ſeven weeks; keep them weeded during ſummer, and in winter it may not be amiſs to protect the *Cytiſus Nigricans* and *Cytiſus Hirſutus*, by occaſional ſhelter of mats, during ſevere froſt; and in ſpring following, the ſeedlings in general, if they ſtand very cloſe, may be tranſplanted into the nurſery, in rows two feet diſtance, the Laburnums and the others a foot; allowing them more room as they advance in growth; and here they may remain two, three, or four years, till large enough for the ſhrubbery.

By cuttings.—Moſt of the deciduous ſorts will alſo ſucceed this way, and October and November is the beſt time for planting them. Chuſe young ſhoots eight, ten, or twelve inches long, plant them in rows a foot apart, and five or ſix inches in the lines; and they will be rooted in one year.

All the culture theſe plants require in the nurſery, is to keep them clear from weeds, and to dig the ground annually between the rows.

# D.

DAPHNE, Spurge Laurel, and Mezereon.

This genus conſiſts of low ornamental ſhrubs, of the evergreen and deciduous tribe, adorned with ſpear-ſhaped leaves, and ſmall, but numerous, monopetalous, four-parted flowers.

Claſs and order, *Octandria Monogynia.*

*Characters.*] CALIX, none. COROLLA is monopetalous, funnel-ſhaped, and divided into four oval ſpreading ſegments. STAMINA, eight ſhort filaments inſerted into the tube, and erect bilocular antheræ. PISTILLUM, an oval germen, ſhort ſtyle, and a capitated depreſſed ſtigma. PERICARPIUM, a roundiſh unilocular berry and one ſeed.

There are ſeven or eight ſpecies, but not more than two common to the Engliſh gardens, and which are the moſt beautiful and the only ſorts that demand particular attention in horticulture.

The firſt is an evergreen, and the ſecond is deciduous, viz.

1 DAPHNE *Laureola.*

*Laureole, or Spurge Laurel.*] Daphne, with many greyiſh-coloured ſtalks from the root, branching irregularly three or four feet high, cloſely garniſhed with thick, ſpear-ſhaped, ſmooth, ſhining, evergreen leaves, ſitting cloſe to the branches; and from the upper parts, numerous, ſmall, yellowiſh-green flowers in cluſters, ſucceeded by oval berries, ripening to a black colour; flowers in January and February, and the ſeeds ripen in June.

*Variety.*] Variegated-leafed Laureola.

2 DAPHNE *Mezereon.*

*The Mezereon.*] Daphne, with a ſhort, ſtrong, woody ſtem, branching out low into many erect branches, forming a regular buſhy head, four or five feet high, garniſhed with ſmall, ſpear-ſhaped, deciduous leaves about two inches long, and the upper parts of all the branches and young ſhoots cloſely adorned with numerous flowers, by threes, coming out early before the leaves, of different colours in the varieties, and ſucceeded by many roundiſh berries, in ſome yellow, others red.

*Varieties.*

*Varieties.*] Mezereon with white flowers and yellow berries—Purple flowers and red berries—Pale-red flowers and red berries—Crimſon flowers and red berries—With variegated leaves, ſtriped with yellow.

The flowers of both theſe ſpecies and reſpective varieties conſiſt each of one four-parted petal, very ſmall, but numerous, and thoſe of the Mezereon are the moſt conſpicuous and beautiful; all the ſorts flower early, and are ſucceeded by many berries, each furniſhing one ſeed; ripe in June and July.

Both the ſpecies are very hardy, and proſper in any ſituation and ſoil of a garden.

The firſt ſpecies, *Daphne Laureola*, is an inhabitant of our woods, and being a hardy and delightful little evergreen is peculiarly adapted for wilderneſs and wood-works in gardens, as it will flouriſh under larger ſhrubs and the drip of trees; is alſo proper for any other ſhrubbery departments, no weather hurts it, and remains always green.

The *Mezereon* and varieties are all deciduous, but flower remarkably beautiful in February and March before the appearance of leaves, every ſhoot being covered with flowers, are extremely ornamental at that early ſeaſon, as well as very diffuſe in a moſt agreeable fragrance; and when they fade, the leaves advance, and the berries continue their growth, ripening in June and July; which have alſo a pretty effect in forming variety, but are generally ſoon devoured by the birds.

The ſeveral varieties are proper ornamental furniture for gardens of any extent, and ſhould occupy the moſt conſpicuous parts of ſhrubbery-works contiguous to lawns, principal walks, and places near the habitation.

Every part of thoſe ſhrubs are of a remarkably hot quality, particularly the root, which is uſed in medicine; for which purpoſe ſome gardeners near London, cultivate many of the Mezereons to ſtand ſeveral years to acquire large roots, then dig them up occaſionally, cut off the root, and ſell them for three or four ſhillings per pound to the druggiſts and phyſic-herb-ſhops.

### *Propagation.*

Both ſpecies are raiſed with facility from ſeeds, i. e. the berries which the ſhrubs furniſh in great plenty, if ſecured from birds, by netting them, as ſoon as they begin to ripen.

The ſeeds grow freely in the common ground, and the beſt time for ſowing them is in autumn, ſoon after they are ripe; and there will be a chance of their coming up the ſpring following, otherwiſe, when not ſowed till ſpring, they often remain a whole year before they germinate. Having procured the berries, dig a bed of light earth, and rake it fine; then, either draw an inch of earth off the ſurface, and ſow the ſeed, and cover them over with earth, or draw flat drills that depth and ſix inches diſtance, ſow the berries therein, earth them over as above, and ſmooth the ſurfaee.

The plants will appear in April or May; keep them weeded all ſummer, and in autumn or ſpring following, if they ſhould ſtand very cloſe in the ſeed-bed, the largeſt may be tranſplanted; otherwiſe they may remain until the ſecond autumn till October, then plant out the whole in the nurſery, in rows eighteen inches diſtance, to remain till two or three feet high, and are then fit for the ſhrubbery.

DATURA, Thorn-Apple, formerly *Stramonium.*

This genus furniſhes ſome herbaceous, large, erect, flowery annuals for the pleaſure-ground, riſing three or four feet high, branchy, and adorned with very large, oval, and heart-ſhaped leaves, and conſiderable funnel-ſhaped flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, oblong, tubular, ventricoſe, five-angled, and indented in five parts. COROLLA is monopetalous, funnel ſhaped, having a long cylindrical tube, a pentangular ſpreading limb, riſing at the angles into acute points. STAMINA, five awl-ſhaped filaments, and oblong compreſſed antheræ. PISTILLUM, an oval germen, erect ſtyle, and thick obtuſe ſtigma. PERICARPIUM, an oval, bilocular, quadrivalvular capſule, and numerous kidney-ſhaped ſeeds.

There are about four ſpecies in the Britiſh gardens, all of them annual, and of erect ſtrong growth, riſing each with a ſingle luxuriant ſtem, dividing into many ſpreading branches.

The ſpecies are,

1 DATURA *Stramonium.*

*Stramonium, or Common Thorn-Apple.*] Datura, with an erect, ſtrong, round, hollow, green ſtalk, branching luxuriantly a yard high, having the branches widely extended on every ſide; large, oval, irregularly-angulated, ſmooth, dark-green leaves; and from the

the diviſions of the branches large white flowers ſingly, ſucceeded by large, oval, prickly capſules, growing erect, commonly called Thorn-Apples.

This is often found wild upon dunghills, but is often cultivated in gardens for variety; where, if the ſeeds are ſuffered to ſcatter, numbers of young plants will riſe naturally for ſeveral years after.

[2]DATURA *Tatula.*

*Tatula, or Great Purple Stramonium.*] Datura, with an erect, large, purple ſtalk, branching four or five feet high, and widely on every ſide, large, heart-ſhaped, angulated, indented, ſmooth leaves; and, from the axillas of the branches, long purple flowers ſingly, ſucceeded by oval, ſpinous, erect capſules.

*Variety.*] With white flowers.

[3]DATURA *Metel.*

*Metella Nut, or White African Thorn-Apple.*] Datura, with an erect large ſtalk, branching two or three feet high, large heart-ſhaped, almoſt entire, downy leaves, and, from the axillas of the branches, long, widely expanded, pure white flowers ſingly, ſucceeded by ſpinous drooping capſules.

*Variety.*] With double flowers.

[4]DATURA *Faſtuoſa.*

*Ægyptian Purple Thorn-Apple.*] Datura, with an erect, purple, ſhining, ſmooth ſtalk, branching three or four feet high, large, ſinuated, ſmooth leaves, and, from the axillas of the branches, large widely-expanded flowers, purple without, and pure white within, ſucceeded by globular drooping capſules, ſet with many blunt tubercles.

*Varieties.*] Ægyptian Thorn-Apple with ſingle flowers—ſemi-double flowers—and with double flowers.

The flowers of all theſe annuals are univerſally of one large funnel-ſhaped petal, having a long tube and ſpreading pentagonal limb, ſucceeded by large roundiſh capſules the ſize of middling apples, which being cloſely ſet with ſharp ſpines, derived the name Thorn-Apple.

They all flower in June, July, and Auguſt, and are ſucceeded by capſules in autumn, furniſhing abundance of ſeeds.

The firſt and ſecond ſpecies are hardy, and eaſily raiſed in the natural ground.

But the third and fourth ſorts are tender, and require to be raiſed in a hot-bed, and from which, either tranſplanted into pots, or in the borders of the pleaſure-ground.

The ſpecies in general are conſidered as plants of ornament, though the firſt ſort often becomes a troubleſome annual weed; but this and the ſecond merit a place in large borders for variety; and the third and fourth ſpecies, and reſpective varieties, being extremely beautiful in their flowers, demand admittance in the collection of curious annuals. See ANNUAL PLANTS.

*Propagation, &c.*

The hardy ſorts may be ſown in autumn or ſpring, in the borders and other compartments of the pleaſure-ground where you deſign they ſhall flower; ſowing them in patches four or five ſeeds in each, half an inch deep; and when the plants come up, thin them to one of the ſtrongeſt in each patch.

But the third and fourth ſorts muſt be ſown in March, in a hot-bed, under frames and glaſſes, in common with other tender annuals, ſuch as balſamines, egg-plants, marvel of Peru, &c. See ANNUAL PLANTS. When they come up, admit air daily by tilting the lights; and in April, when the plants are two or three inches high, prick ſome ſingly in pots, and plunge them alſo in a hot-bed, as directed for amaranthus, cock's comb, &c. to forward them, and draw them up tall; others may be pricked in the earth of the hot-bed, ſix inches diſtance; and in June, the whole ſhould be moved into the open air, placing thoſe in pots to adorn fore-cours, and the reſt may be taken up with balls, and planted in the compartments of the pleaſure-garden.

DAUCUS, the Carrot.

This genus furniſhes ſeveral herbaceous ſpecies, but of which only one claims eſteem for general gardening, which is a biennial eſculent, moſt valuable for its large eatable root, and which is the *Daucus Carota*, or Common Carrot; the others having but little merit, either for uſe or ornament, are rarely cultivated.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, an umbellate flower, compoſed of many ſmaller umbels, the general umbel having a many-leafed involucrum, which for the partial umbels is more ſimple and ſhort. COROLLA, a radiated, difform, general umbel, having numerous florets, each compoſed of five, heart-ſhaped, inflexed petals. STAMINA, five filaments, and ſimple antheræ. PISTILLUM, a ſmall germen under each floret, two reflexed ſtyles, and

and obtuſe ſtigma. PERICARPIUM, none. SEMEN, a ſmall, two parted, hairy fruit, each having two ſeeds.

The ſpecies denominated Carrot is,

DAUCUS *Carota.*

*Carota, or Carrot* ] Daucus, with a large, long, taper, perpendicular root, fifteen or eighteen inches long, crowned by many long, erect, finely-divided leaves, and when it ſhoots for ſeed, an upright ſtalk, branching out three or four feet high, having all the branches terminated by large white umbels, in May and June, ſucceeded by hairy ſeeds in Auguſt.

Of this ſpecies there are ſeveral varieties, in reſpect to the colour of the root, though there is only one ſort in general eſteem.

*Varieties are*] Carota with an orange-coloured root, commonly called *Orange Carrot* —With a red root—With a purple root—With a yellow root—With a white root—— all of them wholeſome for eating.

They are all biennial, riſing from ſeed one year, and obtain perfection; and the next they ſhoot up into ſtalk, produce flowers and ſeed, and the root ſoon after dies.

Of theſe varieties, the firſt ſort, *Orange Carrot*, is that which is moſt proper for general culture; it grows longer, larger, and commonly of more handſome growth than the others; as, when cultivated in a light, looſe, deep ſoil, they often grow fifteen or eighteen inches long in the eatable part; and from two to three or four inches diameter at top, diminiſhing gradually in ſize to the lower end; but as one method of culture ſuits the whole, a few of the others may alſo be raiſed by thoſe who are fond of variety, as they are all eaſily raiſed in any quantity from ſeed annually, ſown at almoſt any time of the year, though the ſpring is the proper period for ſowing the general crops.

The principal ſeaſon of Carrots is from June until Chriſtmas; but by different ſowings, as hereafter mentioned, they may eaſily be obtained throughout the year.

*Propagation and Seaſons for ſowing.*

All the varieties are propagated by ſeed annually in ſpring; or, to obtain a greater ſucceſſion, may be ſowed at three or four different times of the year; obſerving, however, that the principal ſowing ſeaſon is, from about the middle of February to the latter end of March, being the only proper period for ſowing the main or general crop, which will furniſh a ſupply of Carrots from June till March following.

However, when young Carrots are required as early as poſſible, and a ſucceſſion of ſuch to be continued during ſummer and autumn, &c. four different ſowings ſhould be performed in the following order:

The firſt or early ſowing to be about Chriſtmas, or in the beginning, middle, or any time of January, in mild dry weather, on a warm rich border, or in any rich, dry, ſheltered ſituation; they will come in for uſe early in May.—But as theſe early crops are not always ſo ſucceſsful as thoſe of the February or March ſowings, no conſiderable ſpace of ground ſhould be ſowed, only a little to come in a few weeks before the general crop.

The ſecond ſowing, or main crop, may be performed towards the latter end of February, or firſt or ſecond week in March, but not later than the end of that month; though ſowings in April or May will ſucceed, but then the Carrots will ſcarcely acquire half the ſize of thoſe ſown in February and March; therefore mark this for the main crop, as from which ſowings we may obtain good Carrots from June till March following, that is, it will furniſh fine young Carrots in June and July, but will be of a handſome large ſize in Auguſt, and by the end of September or October, they will be arrived to full perfection, which in November ſhould be taken out of the ground, and preſerved in ſand for winter and ſpring uſe, becauſe, if left longer in the ground after being arrived at full growth, they would canker, and rot away in winter.

The third ſowing, effected about the middle of July, will furniſh a ſupply of young Carrots in the latter end of September, October, November, &c.

And, a fourth ſowing is performed about the middle or latter end of Auguſt, to ſtand the winter for an early ſpring crop; for the plants coming up in September, continue a ſlow growth all winter, till retarded by froſt; and then, if ſheltered in very ſevere froſts by a light covering of dry long litter, juſt to preſerve their tops or leaves entire, will be of much advantage, and you will obtain young Carrots in March and April, or till thoſe of the early ſpring-ſowing come in: theſe autumn ſown Carrots, however, are apt to be tough and ſticky, but as they come at an early ſeaſon, when young Carrots are a rarity, they are, therefore, nevertheleſs always acceptable both for

for family-uſe and in market, and with which the London gardeners ſupply the markets plentifully from March until May, or till the arrival of the early ſpring-ſown crops.

Early Carrots may alſo be obtained by aid of artificial heat. See their *Culture in Hot-beds.*

*Of the proper Soil for them, and its Preparation.*

The ſoil moſt proper for Carrots is that which is light, looſe, and of ſome conſiderable depth; and if inclinable to a ſandy nature, in a moderate degree, it will be an advantage; it is therefore neceſſary always to chuſe a ſpot of the lighteſt and deepeſt ſoil in the garden, and ſuch as hath been heretofore enriched with proper manure, obſerving, if it has been dunged the preceding year, it is more eligible than dunging it the ſame ſeaſon, as freſh dunged land is apt to promote worm-eaten, or a ſort of canker in the roots of the Carrots; but where the ground is ſo poor, that you conceive dunging is neceſſary, uſe that which is thoroughly rotted, and ſpread it evenly over the ſurface of the ground, to be trenched in regularly.

As to ſituation, an open expoſure free to the ſun and air, as diſtant from ſpreading trees as poſſible, ſhould be choſen, eſpecially for the main crops, which ſhould always be in the large open quarters.

The neceſſary ſpace of ground to ſow for family ſervice is, for the main crops, from about two or three to fifteen or twenty rod, according to the ſize of the family.

The ground ſhould be trenched one full ſpade deep at leaſt; but, where the depth of proper ſtaple will admit, it is adviſeable to trench it two moderate ſpades depth; for as Carrots often ſtrike two feet perpendicularly into the ground, they conſequently require a conſiderable depth of looſe ſoil, whereby the ſwelling part of the root will be long, ſtraight, and of large ſize; obſerving likewiſe, that it is adviſeable for the ground to be trenched up in rough ridges in winter ſome months before the ſowing ſeaſon, that it may be well meliorated by the weather, which will be of ſingular advantage, and is particularly neceſſary for the early and general crops; and at ſowing time, it is ſoon levelled down for the reception of the ſeed: it is alſo of much importance in trenching the ground to take but thin ſpits, and break all large clods, ſo as the parts may be well ſeparated or divided, that the roots may have full liberty to perform their perpendicular growth; for when obſtructed in that by the too compactneſs or lumpineſs of the earth, they grow ſhort, branch or divide into forks, and become very irregular.

Having therefore ridged the ground, as above, in winter, then, at the ſowing-ſeaſon, take advantage of dry fine weather to level it down for ſowing, ſtir every part, and preſerve a level ſurface; and, as ſoon as the ground is thns prepared, if the ſurface is not wet, but will readily rake without clogging, directly ſow the ſeed, at leaſt the ſame day, while the earth is freſh ſtirred, and before rain falls to wet the ſurface and render it cloggy, or is too much dried by the ſun and wind; and the following is the method of ſowing.

*Method of ſowing the Seed.*

Always, if poſſible, procure new ſeed of the former year's ſaving, for that which is more than one year old never grows freely; the neceſſary quantity is, at the rate of about a pound and a half to an acre; ſo that for the largeſt family garden, a quarter of a pound is ſufficient, and is ſeldom more than a ſhilling or eighteen pence per pound.

It muſt be ſowed by broad-caſt, or ſcattered as equally as poſſible all over the ſurface of the ground, and raked in.

A calm dry day muſt be choſen for ſowing this ſeed, otherwiſe being of very light ſubſtance, the wind would blow it away; but previous to ſowing it, as beſides its being of the above light nature, it adheres cloſely together by its rough hairy borders, it is proper to mix therewith ſome ſand or fine dry mold, rubbing the whole between the hands, both to ſeparate the ſeeds, and cauſe the ſand to adhere a little, to render them more weighty; by this means you will be able to ſow it regularly, which otherwiſe would be apt to fall in heaps; then having prepared the ground, as before directed, ſow the ſeed on the ſurface, moderately thin, and directly rake it in; or the ground may previouſly be formed into five feet wide beds, having ſpade-wide alleys between, which may be neceſſary in moiſt or heavy ſoils, or when it is deſigned to thin out the Carrots by degrees for uſe, ſo may ſtand in the alleys to ſow, and rake in the ſeed, alſo to thin out the young Carrots occaſionally, without treading on the beds to bind the earth too cloſe. But where the

ground is light, looſe, and dry, the ſeed may be ſown all over the piece; then tread the ground over evenly with the feet almoſt cloſe together, taking ſhort ſteps, being neceſſary both to bury the ſeed more equally, and ſettle the ground evenly in every part, that when you ſtand to rake it, the feet will not ſink in holes, in which the ſeed would be unavoidably drawn in raking; therefore, as ſoon as the ſeed is ſown, and trodden in as above, rake the ground over evenly with a large wide-teethed rake, either a wooden or iron one; raking once in a place is ſufficient, and as you go on trim off all large ſtones, and the work is done.

The ſeed being thus ſown, it, if good, will ſoon germinate, and the plants will appear in fifteen or twenty days, and ſometimes in a little leſs, or longer time, according to the ſeaſon of ſowing, nature of the ſoil, and temperature of the weather. When they are two or three inches high, they muſt be thinned to ſeveral inches diſtance, and cleared from weeds, agreeable to the following directions.

*Culture of the Plants.*

When the young plants are come up about two or three inches high, they ſhould be thinned to about ſix, eight, or ten inches diſtance, according to the ſize you intend they ſhall grow, and at the ſame time muſt be well cleared from weeds.

This work may either be performed by hoe or hand; but hoeing is not only more expeditious, as by looſening the ſurface of the earth about the young plants, it will prove a very eſſential ſervice in promoting their progreſs of growth. A ſmall hoe two or three inches wide ſhould be uſed; and dry weather ſhould be choſen for performing the work, that the ſuperabundant plants and weeds, as they are hoed down may die, for if done in moiſt weather, many would ſtrike root as they lie, and grow again. In the courſe of the work, be careful to thin the plants regularly to five or ſix inches diſtance at leaſt, which may be ſufficient, if the Carrots are deſigned to be uſed while young, and thinned out by degrees for uſe; but if intended to have them ſtand to grow to full ſize, hoe them at once to eight or ten inches diſtance, ſingling out the moſt promiſing to ſtand, and leave no where two or more together; obſerving to cut up all weeds, and ſtir every part of the ground between all the ſtanding plants.

In a fortnight, or three or four weeks after, as you ſhall ſee occaſion, run over them again with a hoe, to cut up any ſtraggling ſuperfluous plants that eſcaped you in the firſt hoeing, cutting up alſo all weeds, and the plants will ſoon after cover the ground, and require no farther culture.

In a month, or five or ſix weeks after the firſt hoeing, you may expect young Carrots fit to draw, which, if much wanted, may begin drawing when they are the ſize of your little finger; beginning with thoſe which were left cloſe on purpoſe for thinning, and thin them out for the table as they are wanted, in a regular manner, ſo as the remainder may have room to arrive at full growth.

But when it is deſigned to begin drawing Carrots for table when quite young, it is adviſeable, excluſive of the main crop, to ſow a piece purpoſely for drawing; and when fit to hoe, thin them only four or five inches diſtance, and in May or June, when of due ſize for the table, by a gradual thinning out the largeſt for uſe, the others will gain more and more room daily; and thus a piece of Carrots may be continued in occaſional drawing till the main crop is arrived nearly at full growth in Auguſt and September, and which may be taken up clear as they come to hand.

Therefore, to have the principal crop of Carrots as fine as poſſible, they, when fit for hoeing, ſhould be hoed to the full diſtance at firſt, of eight or ten inches, as before obſerved, and ſuffer them to ſtand until Auguſt or September, before you begin drawing, when they will be long, large, and of handſome growth, and in October or beginning of November will be done growing, and ſhould be then taken up and laid in ſand for winter, as hereafter directed; which, where there is convenience to lay them, is the only method by which Carrots can be preſerved in due excellence during that ſeaſon.

Carrots deſigned for market ſhould, during ſummer and autumn, whilſt they remain in the ground and have leaves, be waſhed, bound in bunches by their ſaid leaves, ſpreading the roots or Carrots themſelves fan-faſhion, twelve or eighteen, according to their ſize, in each bunch, which in the London markets ſell from about eighteen pence to three or four ſhillings per dozen of bunches, according to the early or late period of the year, and ſize of the Carrots.

But in winter, as being devoid of tops, they are commonly brought looſe in maunds or other large baſkets, and ſold by the baſket, or, if large, by the ſcore of roots.

*Preſerving them in Sand during Winter.*

To preſerve Carrots in good perfection through the winter, the full-grown crops ſhould be taken out of the ground in November, when they have done growing, and the leaves begin to turn yellow and decay; and lay them in ſand in a dry place out of the wet, and the reach of froſt.

This is neceſſary for theſe reaſons, firſt, that if permitted to remain in the ground in winter, they would be attacked by vermin, and become cankery and rotten, and in moiſt fat ſoils will often waſte away to nothing: likewiſe, if they remained in the ground in winter, hard froſts prevent you digging them up when wanted; but by taking the roots out of the ground in autumn, they may be preſerved perfectly ſound till March or April following, and will be ready for uſe in all weathers.

They ſhould be taken up in dry weather, with a three-tyned fork, and ſpread regularly on the ground for a few hours to dry; then cut their leaves off cloſe, and clear off all adhering earth, and carry them into a dry ſhed or other room, where they may be ſheltered from wet and froſt; there lay them in dry ſand, firſt laying ſome ſand, then a layer of Carrots, then more ſand, and ſo proceed alternately, ſeveral layers one upon another, and as wide and long as convenient, in proportion to the quantity of roots to be thus preſerved; covering the whole half a foot thick with ſtraw.

By the above practice Carrots may be preſerved in fine condition till April, both for family uſe and market.

Vaſt quantities of Carrots, preſerved as above, are brought to London every winter from Sandwich in Kent; the grounds adjacent being of a ſandy nature, is famous for producing the largeſt Carrots in England, ſome of which I have ſeen of a prodigious bulk; they are generally brought up by water, and depoſited in the warehouſes in Thames-ſtreet and Tooley-ſtreet, and places adjacent near London bridge, and there ſold by the buſhel, the price commonly a ſhilling or eighteen pence.

It is worth while to purchaſe ſome of theſe for ſeeds.

*Raiſing them early in Hot-beds.*

Young Carrots may be obtained at an early ſeaſon by aid of hot-beds; therefore if you omitted an autumnal ſowing in the full ground, for early ſpring ſervice, or that thoſe are damaged in winter, recourſe may be had in January or early in February to a ſowing on a hot-bed, either under frames or occaſional ſhelter of mats.

Make the hot bed of hot dung, four feet wide, as long as convenient, and two feet high, and directly frame it, and put on the mold eight or ten inches deep, or for want of frames, may arch it with hoops to be covered with mats, firſt earthing the bed the above depth with light rich mold, and fix boards or a wreath of large ſtraw bands round upon the edge of the bed on the top of the dung to keep up the outſide earth, or it might be banked up cloſely on each ſide and end with moiſt ſoil, as practiſed for aſparagus hot-beds: then having levelled and ſmoothed the earth for the reception of the ſeed, ſow it evenly on the ſurface, and beat it lightly down with the back of the ſpade, and then ſift ſome fine mold over it a quarter of an inch thick: this done, arch the bed over with hoops, and every night and all ſevere weather cover it with mats, or, if you uſe a frame and glaſſes, the plants muſt be allowed the full air every mild day, by ſhoving off the lights; for the plants muſt not be kept cloſe, otherwiſe they would draw up weak and never ſwell at root, ſo muſt only be covered principally on nights, and very ſevere or cold cutting weather.

When the plants are come up, and have two or three leaves an inch high, thin them by hand to three inches diſtance, which will be room enough, as they will be moſtly drawn off for uſe while quite young.

They may be greatly forwarded in growth, by lining the bed on each ſide with hot dung, in a fortnight or three weeks after it is firſt made, and ſo repeat it once or twice more, according as the heat declines.

By this practice of raiſing Carrots in hot-beds, a few may be obtained for variety, a month at leaſt ſooner than any in the natural ground.

*Raiſing them in Fields.*

Field culture of Carrots is ſometimes practiſed for feeding cattle, and ſometimes in large quantities for the ſupply of markets, and

either of which differs but little in culture from that in gardens, only the ground is generally prepared by ploughing and harrowing, inſtead of digging and raking, and the proper time for ſowing is March.

The ground ſhould be naturally light, looſe, of tolerable depth, and in good heart, as obſerved in the garden culture, and ſuch that have been in tillage before; and if it has been dunged the preceding year, it will be a particular advantage; otherwiſe if the land is poor, ſome thoroughly rotten dung may be ſpread over the ſurface, and ploughed in. The ground ſhould be ploughed fifteen or eighteen inches deep, if the depth of good ſtaple will admit, which is effected by double ploughing, i. e. ploughing twice in the ſame furrow; and two different ploughings at leaſt is neceſſary, but if three, it will be much the better, that is, the firſt ſhould be in the beginning of winter, turning it up in high ridges; the ſecond is proper in January or beginning of February, acroſs ways the firſt; and the third and final ploughing ſhould be in March, and ſhould then be well harrowed to break the clods, and ſmooth the ſurface for the reception of the ſeed: this is to be ſown in the broad-caſt way, allowing a pound and half to an acre, mixing ſome ſand or dry mold with the ſeeds, to enable you to ſcatter them more regularly, as in the garden culture. As ſoon as they are ſown, harrow them in with a light harrow, and afterwards, when the ſurface is dry, roll the ground with a wooden horſe roller to ſmooth the ſurface, whereby the ſeed will be more effectually covered, and the plants will riſe more evenly.

When the Carrots are come up about three inches high, they muſt be hoed in dry weather, to thin them and deſtroy weeds; having a five or ſix-inch hoe, cut out the plants to eight or ten inches diſtance, ſtirring all the ground, and cut up all weeds; and in three or four weeks after, if weeds make their appearance, run over them again with the hoe, and they will require no further culture.

They will be grown to a large ſize in Auguſt and September, and be then fit for uſe; but if they are deſigned chiefly for winter eating, they ſhould ſtand till November, then dug up, and laid in ſand, to preſerve them, as directed for the garden crops.

*Saving the Seed.*

To ſave Carrot ſeed, you may either leave ſome of the main crop in the ground in autumn, at a foot diſtance, for that purpoſe; or, in ſpring, plant out a quantity of the fineſt of thoſe which were taken up in autumn, and preſerved all winter in ſand.

But thoſe which have been taken up and preſerved in ſand are preferable, eſpecially for one thing; the roots being out of the ground, you can readily ſee and judge of their goodneſs, ſo as to ſelect only ſome of the handſomeſt for planting, making choice of ſuch whoſe tops are not cut too cloſe to ſpoil the ſhoot for the flower-ſtalk; they ſhould be planted in February, in rows two feet diſtance and one foot apart in the lines, planting them perpendicularly and wholly into the ground about half an inch over their crown; they will readily take root, and ſhoot up flower-ſtalks, and require no other culture than hoeing occaſionally to deſtroy weeds.

They will ſhoot up into ſtalk in April and May, be in full flower in June, and ripen ſeeds in Auguſt, which ſhould then be cut in dry weather, and ſpread in the ſun and air a few days till thoroughly dry, then threſh it out, and put it up in bags.

This ſeed will ſometimes retain its growing property two or three years; however, never depend on any but one year old ſeed for any principal crop, nor ſhould the ſeedſmen ſerve their cuſtomers with any that is older, as I am ſure it would prove a great diſappointment.

DELPHINIUM, Dolphin-flower, commonly called Larkſpur.

The plants are hardy, herbaceous, flowery annuals and perennials, of upright growth, from about a foot and a half to four feet high, garniſhed with finely-divided leaves, and terminated by long ſpikes of pentapetalous flowers.

Claſs and order, *Polyandria Trigynia.*

*Characters.*] CALIX, none. COROLLA, five irregular petals, the upper one extended at the baſe into a tubular obtuſe tail, and a bifid nectarium in the centre. STAMINA, many filaments, and ſmall erect antheræ. PISTILLUM, three oval germina, three ſtyles, and reflexed ſtigmas. PERICARPIUM, three united unilocular capſules, and many angular ſeeds.

There are about four ſpecies of *Delphinium* common to the Engliſh gardens, all of them conſidered as flowery plants, two of which are annual, and the reſt perennial, viz.

1 DELPHINIUM *Ajacis.*

*Ajacis, or Unbranched Annual Larkſpur.*] Delphinium, with an upright, ſimple, unbranching ſtalk, two or three feet high, garniſhed

niſhed with finely-divided leaves, and terminated by an erect long ſpike of flowers, having monophyllous nectariums, and of different colours in the varieties.

*Varieties are*] Unbranched Annual Larkſpur, with ſingle and double blue flowers—Single and double purple flowers—Single and double red flowers—Single and double white flowers—Single and double ſilver-coloured flowers—Single and double violet-coloured flowers—Single and double aſh-coloured flowers—Single and double ſtriped flowers.

All theſe varieties of *Delphinium Ajacis*, or Unbranched Larkſpur, riſe with a ſimple ſtem, ſcarce emitting any ſide branches; and each ſtalk is terminated by a very long, erect, flowery ſpike, compoſed of numerous cloſely-placed flowers, which exhibit a very ornamental appearance in June, July, and Auguſt, ſucceeded by plenty of ripe ſeed in September.

[2]DELPHINIUM *Ambiguum.*

*Branched Annual Larkſpur.*] Delphinium, with an upright very branchy ſtalk three feet high, long finely-divided leaves, and all the branches terminated by long aſcending ſpikes of flowers, having monophyllous nectariums, and of different colours in the varieties.

*Varieties.*] Nearly the ſame in colour as the Unbranched Larkſpur, and of which are ſingles and doubles.

All the varieties of this ſpecies ſend out many branches horizontally, which turn upward toward the extremity, the flowers large, but rather thinly placed in the ſpikes; they all, however, form a very ornamental variety in the borders, &c. in July and Auguſt, ſucceeded by plenty of ſeeds in autumn.

[3]DELPHINIUM *Elatum.*

*Tall Perennial Bee Larkſpur.*] Delphinium, with ſeveral upright ſtalks four or five feet high, adorned with hairy leaves, cut into many broad expanded ſegments, and all the ſtalks terminated by long erect ſpikes of blue flowers, having diphyllous nectariums, with bifid lips, bearded at the top.

[4]DELPHINIUM *Grandiflorum.*

*Dwarf, Grandiflorous, Perennial, Bee Larkſpur.*] Delphinium, with upright branchy ſtalks a foot and a half high, ſmooth leaves, compoſed of many narrow ſegments, ending in ſeveral points, and towards the upper part of the ſtalks large azure-coloured flowers ſingly, having diphyllous nectariums, with entire lips, appearing in July, ſucceeded by ſeed in autumn.

Of theſe four ſpecies the two firſt and varieties are univerſally annual, but the third and fourth are perennial in root and annual in ſtalk, which riſe in ſpring, and decay in autumn.

The names Larkſpur and Bee Larkſpur are derived from the reſemblance of the tail of the corolla to the ſpur of a lark's foot; and from the nectarium of the perennial ſorts to a bee.

The flowers of all the ſorts are compoſed of five unequal petals, one at top, two ſideways, and two at bottom, and a central nectarium; they are moderately large, numerous, and moſtly collected into erect ſpikes, and are very conſpicuous and ornamental.

All the ſorts are very ornamental furniture for the borders and other compartments of the pleaſure-ground, and are ſo hardy that they proſper in any common ſoil and expoſure, and all the ſorts are raiſed abundantly from ſeed in the full ground, as directed below.

*Propagation and Culture.*

The two annual ſorts and varieties are raiſed from ſeed ſowed annually in autumn, i. e. September or October, or early in ſpring, in patches in the places where the plants are to flower, for they do not ſucceed by tranſplantation; obſerving, that thoſe of the autumn ſowing grow ſtronger, flower earlier, and the flowers are generally larger and more durable than the ſpring-ſown plants. It is alſo however proper to ſow ſome in ſpring, in February or March, to continue a longer ſucceſſion of bloom. The method of ſowing them is, dig with a trowel ſmall patches about nine inches diameter in different parts of the borders, towards the middle, or alſo in the fronts of the ſhrubbery clumps, and in each ſuch patch ſow eight, ten, or twelve ſeeds a quarter of an inch deep; and when the plants are an inch or two high, thin thoſe of the unbranched ſorts to about ſix or eight in each patch, and of the branched kinds, to three or four in each place, which is all the culture they require, and in which order of cultivation they will make a fine appearance.

But when intended to have a grand ſhew of them in beds by themſelves, they are commonly ſowed in drills, forming the drills lengthways the beds a foot aſunder, and half an inch deep, ſo ſcatter the ſeeds thinly along the drills, and rake the earth over them evenly; but the unbranched kinds are the beſt adapted for this mode of culture.

Or they may be ſowed broaſt-caſt on the ſurface of the bed, and raked in, and when the

the plants are an inch or two high, thin them by hand or hoe, to three or four inches diſtance, but the branched kinds to treble that diſtance.

To preſerve the varieties of theſe two annual ſpecies from degeneration, all thoſe of bad colours, and that are very ſingle, ſhould be pulled out as ſoon as they ſhew bloom enough to diſcover their properties; for their farina would impregnate the fine ſorts, and cauſe a degeneracy.

The perennial ſorts.—Theſe are alſo raiſed plentifully from ſeeds ſown in autumn or ſpring, in a bed or border of common earth for tranſplantation. Sow them on the ſurface, and rake them in, and when the plants come up, hand-weed them occaſionally, and thin them to three or four inches diſtance, to remain till October or November; then plant them out where they are to remain to flower: their roots will endure many years, increaſe in ſize, and the larger they are, the greater number of flower-ſtalks they produce, ſo as to exhibit a large ſhew of bloom.

DENTARIA, Toothwort, or Tooth Violet (*Dentaria.*)

This genus furniſhes three hardy, herbaceous, flowery perennials, producing annual ſtalks twelve or eighteen inches high, adorned with many-lobed leaves and ſpikes of quadripetalous cruciform flowers.

Claſs and order, *Tetradynamia Siliquoſa.*

*Characters.*] CALIX, four oblong, oval, deciduous leaves. COROLLA, four cruciform petals. STAMINA, four long and two ſhort filaments, and erect heart-ſhaped antheræ. PISTILLUM, an oblong germen, thick ſtyle, and blunt ſtigma. PERICARPIUM, a long, taper, bivalvular, bilocular, pod, and many roundiſh ſeeds.

The ſpecies are,

[1]DENTARIA *Pentaphyllos.*

*Five-lobed Dentaria.*] Dentaria, with upright ſtrong ſtalks a foot and a half high, garniſhed with five-lobed digitate leaves, and terminated by looſe ſpikes of bluſh-cloured flowers.

[2]DENTARIA *Enneaphyllos.*

*Nine-lobed Dentaria.*] Dentaria, with upright ſtalks a foot high, garniſhed with ternate trifoliate leaves, being compoſed of nine lobes by threes, and the ſtalks crowned by branches of purpliſh flowers.

[3]DENTARIA *Bulbifera.*

*Bulbiferous Seven-lobed Dentaria.*] Dentaria, with ſlender ſtalks a foot high, the lower leaves pinnated and ſeven-lobed, the upper ones ſimple, and the ſtalks bearing bulbs at their ſides, and the top crowned by cluſters of purple flowers.

The flowers of all theſe three ſpecies are compoſed of four cruciform obtuſe petals, and are collected into ſpikes or cluſters at top of the ſtalks, appearing in ſummer, and are ſucceeded by plenty of ſeed.

The plants are all of the flowery tribe, perennial, hardy, and delight moſt in ſhade; they are therefore proper furniture for the borders of ſhady walks, and ſuch like departments.

They are propagated by ſeed, and by parting the roots.—Sow the ſeed in autumn ſoon after it is ripe, or early in ſpring, in a ſhady border of light earth, and when the plants are three inches high, may be planted where they are to remain, and they will flower the year following. By parting the roots, it may be done in October or November, or early in ſpring.

The bulbs produced on the ſides of the ſtalks of the *Dentaria bulbifera*, taken off and planted, readily become plants.

DIANTHUS, Clove Gilliflower, Carnation, Pink, Sweet William, &c.

This genus furniſhes a grand collection of herbaceous, beautiful, flowery perennials and biennials, of hardy growth, for the pleaſure-ground, all of them fibrous-rooted, crowned with leaves all the year, ſending up flower-ſtalks annually from one to three feet high, adorned at top with very conſpicuous, pentapetalous, ſolitary, and aggregate flowers.

Claſs and order, *Decandria Digynia.*

*Characters.*] CALIX is long, cylindrical, indented into five parts at top, ſcaly at the baſe, and perſiſtent. COROLLA is in its ſingle ſtate, pentapetalous, with long narrow claws the length of the calix, but the limbs broad, plane, and their edges crenated. STAMINA, ten long filaments, and oval, oblong, compreſſed antheræ. PISTILLUM, an oval germen, two ſtyles, and recurved acuminated ſtigmas. PERICARPIUM, a cylindric unilocular capſule, four-parted at top, and many compreſſed, roundiſh, angulated ſeeds.

There are many ſpecies of *Dianthus*, but not more than four that have any conſiderable merit as garden-flowers, each of which furniſhing ſome beautiful varieties.

For diſtinction ſake we ſhall treat of them under three different heads; firſt, the Gilliflower or Carnation kinds,—ſecond, all the Pink

Pink kind,—and third, all the Sweet William tribe; all under the generical title of *Dianthus*.

*First Head. The Gilliflower or Carnation kinds.*

There is but one ſpecies of Gilliflower or Carnation, but which admit of a profuſion of moſt elegant varieties, all very ornamental flowery plants, for the embelliſhment of the pleaſure-garden, flowering beautifully in July and Auguſt, ſucceeded by abundance of ſeed in autumn.

The ſpecies is,

DIANTHUS *Caryophyllus.*

*Caryophyllus, or Clove Gilliflower, including all the varieties of Carnation.*] Dianthus, with many ſhort trailing ſhoots from the root, garniſhed with long, very narrow, evergreen leaves, and amidſt them upright ſlender flower-ſtalks, from one to three feet high, emitting many ſide-ſhoots, all of which, and the main ſtalk, terminated by large ſolitary flowers, having ſhort oval ſcales to the calix, and crenated petals.

The varieties of this are very extenſive, and unlimited in the diverſity of the flowers.

*Principal varieties are,*

*Common Clove Gilliflower*—having a large, dark, red, ſweet-ſcented flower, ſmelling fragrantly like cloves; hence it derived the name, and of which there are—Single Clove Gilliflower—Double Clove Gilliflower.

*Carnation, ſometimes called Coronation (Coronarius*—having a reddiſh ſingle and double flower—Variegated red and white ſingle and double flower—Variegated red, purple, and white ſingle and double flowers—Variegated red, ſcarlet, purple, and white ſingle and double flower—Variegated red, or purple above, and white underneath, ſingle and double flowers;—and innumerable other intermediate varieties.

But theſe varieties (Variegated Carnations) are by the floriſts divided into four principal claſſes, according to their different modes of variegation, viz.

Flake Carnations—having only two principal colours, diſpoſed in broad flakes or ſtripes quite through the petals.

Bizarre Carnations—having three or four different colours, red, purple, ſcarlet, &c. in different ſhades, variouſly diſpoſed in irregular ſpots and ſtripes.

Piquette Carnations—having always a white ground, pounced or finely ſpotted with red, ſcarlet, purple, or other colours.

Painted Lady Carnation—having the petals a bright red, or purple above, and entirely white underneath.

Each of the above four principal claſſes, though tolerably permanent, admit ſeparately of innumerable varieties, formed, both in reſpect to the luſtre of the different colours, &c. as well as the different modes or diſpoſitions of the ſtripes, ſpots, and other diverſities, in being more or leſs ſtriped with larger or ſmaller ſtripes, or with different colours in the ſame ſtripe, or all of one colour, the ſame is alſo obſervable in the ſpotted or pounced flowers, by the ſpots being either more frequent, or thinly ſcattered, or large or ſmall, and ſuch like variegations; and by which the floriſts form new varieties, acquired by raiſing ſome every year from ſeed; for from the ſeed of the varieties of each reſpective claſs indefinite numbers of new ones are annually gained, varying in ſome particular circumſtances as above, from any that have before appeared, ſo greatly do they vary from ſeed. But it muſt be remarked, that out of a great number ſo obtained from ſeed, there may, probably, be but few that poſſeſs the requiſite properties by which floriſts diſtinguiſh a fine Carnation. However, all good new varieties, of the above four principal claſſes, obtained among profeſſed floriſts, are generally dignified with the name of ſome great perſonage, or that of the perſon who firſt raiſed them, or that of the place where they were raiſed; ſo that including the different parts of the kingdom, there may be many hundred different varieties, known in different places by different titles, as above, that it will be impoſſible to enumerate them here; obſerving, however, that all of them belong principally to one or other of the above claſſes; and that being firſt of all obtained accidentally from ſeed, they are afterwards propagated, and continued only by layers, &c. for ſow the ſeed of any particular ſort, it is a hundred to one if any prove exactly like the parent; but by layers, every one retains all the properties of the mother plant. See their *Propagation*.

The flowers of this ſpecies and reſpective varieties, are, in their characteriſtic or ſingle ſtate, compoſed of five petals, but in the double flowers the petals are numerous, and continued quite to the centre; the doubles are alſo larger, and conſiderably more beautiful, and theſe only ſhould be principally cultivated, which being all firſt obtained accidentally from ſeed, they are continued and increaſed at pleaſure by layers.

The

The doubles are ſometimes amazingly large, meaſuring frequently three or four inches diameter over the crown, eſpecially thoſe ſorts called burſters.

But whole-blowers and burſters are common to moſt of the varieties, more particularly the flakes and bizarres.

The whole-blowers are ſuch whoſe calix, or outer cup, is of long and of equal growth, and opens only at top regularly each way, for the free and equal expanſion of the petals all around; and the flowers of this ſort, though rather ſmaller than the burſters, are always more regular in their natural expanſion, and require conſiderably the leaſt trouble in managing their bloom.

Burſters are ſuch, whoſe cup is large, and ſwoln as it were, and is very apt to burſt open on one ſide, and the petals thereby break out of compaſs, and the flowers become very irregular; but by care in aſſiſting it in due time, by tying and opening the calix a little on the contrary ſide, it may be made to blow regular, and will be very large and handſome.

But the whole-blowers are the beſt calculated for thoſe who have but little time to ſpare, as they will always blow regularly, either in pots or the borders without any attendance.

The properties required to form a good Carnation are, that the ſtem or flower-ſtalk be moderately tall, i. e from about eighteen to thirty inches high, of proportionable ſtrength all the way up, and at the top ſo firm as to ſupport the flower erect, or at leaſt without nodding or hanging much downward. That the flower be large and double, i. e. have numerous petals quite to the very centre, theſe long, broad, and regularly ſpreading; and that when the flower is fully blown, it may be gradually riſing in the middle in a ſpherical manner, and the whole expanding ſo regularly, that the circumference or outer rim be perfectly circular. The colours ſhould be ſtrong, lively, and elegant, the ſtripes and other variegations regular in every part, that no great diſproportion may appear in the diſpoſition of the colouring throughout the petals of the ſame flowers. Theſe properties are principally expected in the fine varieties in pots, deſigned for ſtage flowers.

*Their Uſe in Gardens, &c.*

The fine varieties of this beautiful flower are in univerſal eſteem among floriſts and all curious gardeners, and are of the liſt of prize flowers, that being raiſed in their fulleſt perfection, are carried to floriſts feaſts, to ſhew for a prize, which practice is ſtill much in vogue in many parts; and that the flowers uſually brought to ſuch places, being the production of many different artiſts, according to their utmoſt ſkill, there are often very curious exhibitions of them, in great variety, ſurpriſingly large and fine.

The fine varieties are commonly cultivated in pots, for theſe reaſons—firſt, that they may be readily moved to occaſional protection of a frame or awning of mats, &c. from ſevere froſt in winter; for although the plants are hardy enough to live through the winter fully expoſed, yet, in ſevere ſeaſons, they are ſometimes ſo much cut, that they ſhoot but weakly; but by protecting them from the rigours of hard froſts, they are preſerved in vigour, and they will conſequently be better prepared for ſhooting, and will flower in greater perfection. Secondly, it is proper to retain the fine varieties in pots, in order that, when in bloom, they may be placed upon a raiſed ſtage, covered at top, calculated both to ſhew the flowers to more advantage, by being raiſed two feet from the ground, and by the top being covered, it defends them from the ſcorching rays of the noon-day ſun, and from violent rains, &c. which would greatly impair their beauty, and haſten their decay.—And laſtly, by placing the pots of plants upon a ſtand or ſtage, having the poſts of which ſurrounded at bottom by ſmall ciſterns or pans of water, prevents creeping inſects from coming at the poſts thereof to aſcend to the flowers, particularly ear-wigs; for theſe miſchievous vermin would otherwiſe get into the boſom of the flower, and gnaw the bottom of the petals, that they would all drop out of the calix.

But a due quantity of the more common ſorts ſhould be planted to adorn all the flower-borders and the other conſpicuous compartments of the pleaſure ground; for they will thrive in any common ſoil of a garden, and will flower abundantly in tolerable good perfection; and where there are ſeveral different varieties, they will exhibit a delightful ornamental appearance for ſix weeks, i. e. from the beginning or middle of July until the latter end of Auguſt, being their general ſeaſon of flowering.

Pots of theſe plants, as alſo of pinks and ſweet-williams, may, by way of curioſity, be brought to bloom early in ſpring, by placing them

them in a hot-houſe or forcing-frame in January, February, or March. See FORCING-FRAME.

*The Soil proper for their Culture.*

With reſpect to ſoil, although all the varieties grow freely in almoſt any common garden earth, and in which produce beautiful flowers, yet they are generally ſuperior in that of a light loamy nature, and of which kind of ſoil floriſts generally prepare a compoſt for their fine varieties intendedfor pots as follows:

Provide a quantity of loamy earth, of a light ſandy temperature, from an upland or dry paſture field or common, taking the top ſpit turf and all, which muſt be laid in a heap for a year, and turned over frequently, as directed in the article COMPOSTS; and is then to be mixed with about one third of rotten dung of old hot beds, or rotten neat's dung, and a little ſea-ſand, forming the whole into a heap again, to lie three, four, or ſix months, and will be then excellent for uſe; and if one parcel or heap was mixed with one of theſe kinds of dungs, and another parcel with the other, for different ſeaſons, it will make a change, and may be found very beneficial in promoting the ſize of the flowers.

The above compoſt is as good as can be for thoſe plants, either in pots, or to form into beds.

This compoſt, or any other earth you may uſe for this purpoſe, ſhould not be ſifted, but only well broken with the ſpade and hands. See COMPOSTS.

*Their Propagation by Seed.*

By ſeed.—When great quantities of the plants of this ſpecies are required either to furniſh large grounds, or for market, or that it is intended to raiſe new varieties, it is eaſily effected by ſowing ſome ſeed annually in ſpring, in common earth, and from which the plants will riſe abundantly; and as to varieties, you may always expect ſeveral new flowers of good properties from the plants of each ſowing, and poſſibly not one exactly like thoſe from which the ſeed was ſaved; and that from the ſeed of the fineſt varieties there will probably be many very indifferent, as well as good flowers, ſome ſingle, ſome double, though the ſingles are always conſiderably more numerous than the doubles; but it is from the doubles only we are principally to ſelect varieties for our purpoſe, which are marked when in bloom, to lay for propagation, and the moſt capital of which potted for the ſtage, &c. and the others will do for the common flower-borders.

The ſeaſon for ſowing the ſeed, is any time from about the 20th of March to the 15th of April.

It grows freely in a bed or border of common earth, of the quality of any light rich kitchen-garden mold; though curious perſons often ſow the fine ſorts in pots or boxes, for the convenience of moving them in hot weather, to have only the morning ſun; however, you will ſucceed in either method; and as to ſowing on a bed or a border, may either ſow it on the ſurface, and rake it lightly in, or may firſt rake the ſurface ſmooth, then ſow the ſeed on the ſurface, and ſift over as much light earth as will cover it a quarter of an inch deep: obſerve alſo the ſame method in ſowing it in pots or boxes, giving moderate refreſhments of water in dry weather; and the ſeed will germinate more freely, and the plants riſe regular, and take a free growth.

The plants generally come up in a month after ſowing: give occaſional waterings and weeding, and in July they will be fit to prick out into nurſery-beds, which prepare in an open ſituation three feet wide; and taking advantage of moiſt weather, prick the plants therein four inches apart, and finiſh with a general watering, which repeat occaſionally till the plants have taken good root. Here let them remain till September, when they will be ſo well advanced in growth, as to require more room, and ſhould then have their final tranſplantation into other three-feet wide beds of good earth, in rows lengthways the bed, nine inches aſunder, and the ſame diſtance in the lines, placing them in the quincunx order; and here they are finally to remain all winter, and until they flower, and have obtained an increaſe of the approved varieties of doubles, by layers: and until which periods, all the culture they require is, that if the winter ſhould prove very ſevere, an occaſional ſhelter of mats, during the hardeſt froſt, will be of much advantage, though not abſolutely neceſſary; and in ſpring looſen the ground between them with an hoe, keep them always clear from weeds, and when their flower-ſtalks advance, tye them up to ſticks, eſpecially all thoſe that diſcover by their large flower-pods to be doubles.

They will flower in June, July, and Auguſt, at which times, as ſoon as the ſingles

and doubles are diſtinguiſhable, all the ſingles may be drawn out to make room for their betters, the double varieties.

When theſe are fully blown, examine their properties; the fineſt may be marked for ſtage flowers, and the others as furniture for the borders; all of which may be encreaſed by layers the ſame year, to treble or perhaps ſix or eight times their number or more, ſince each good plant will furniſh from three or four, to ten or twelve ſhoots from the bottom proper for laying, each of which takes root, and becomes a new plant the ſame ſeaſon; and each of theſe again will in their turn furniſh the like number of ſhoots the following years, for the ſame work of propagation; and ſo each variety may be thus annually increaſed to great numbers, and every plant ſo obtained of each reſpective variety, retains all the properties exactly of the mother plant, which is never the caſe of thoſe propagated by ſeed; though from ſeedlings all our fine flowers are always firſt obtained.

Therefore as ſoon as the ſeedlings ſhew bloom, proceed to the work of propagation by layers of all the doubles among them, or at leaſt as many of them as you ſhall approve; and the following is the method of laying them.

*Their Propagation by Layers.*

By layers.—We obſerved above, that the propagation of theſe plants by layers is the only method by which we can with certainty continue any particular variety, either new or old; ſince every layer, becoming a new plant, always produces a flower exactly in ſize, colour, and character, as that of its parent; and that being layed in ſummer, they form roots in ſix weeks, and be fit to tranſplant, and each produce flowers the year following, as well as each furniſh a farther ſupply of ſhoots for more layers.

The proper parts for layers, are thoſe leafy ſhoots ariſing near the crown of the root, which, when about five, ſix, or eight inches long, are of a proper degree of growth for layers.

The general ſeaſon for this work is June, July, and beginning of Auguſt, as then the ſhoots will be arrived at a proper growth for that operation; and the ſooner it is done, after the ſhoots are ready, the better, that they may have ſufficient time to acquire ſtrength before winter: thoſe layed in June and July will be fit to take off in Auguſt and September, ſo will form fine plants by October.

The method of performing the work is as follows.—Firſt provide a quantity of ſmall hooked ſticks for pegs, three or four inches long, with which to peg the layers down to the ground; alſo get ready, in a barrow, a quantity of light rich mold, to raiſe the earth, if occaſion, around each plant; and provide alſo a ſharp penknife. Having all theſe ready, then proceed to the work of laying; firſt ſtrip off all the leaves from the body of the ſhoots, and ſhorten thoſe at top an inch or two evenly, and then fixing upon a ſtrong joint about the middle of the ſhoot, and on the back or under ſide thereof, cut with your penknife the joint half way through, directing your knife upward, ſo as to ſlit the ſhoot up the middle almoſt to the next joint above; by which you form a kind of tongue, on the back of the ſhoot, obſerving that the ſwelling ſkinny part of the joint remaining at the bottom of the tongue muſt be trimmed off, that nothing may obſtruct the iſſuing of the fibres, for the layers always form their roots at that part; this done, looſen the earth around the plant, and, if neceſſary, add ſome freſh mold, to raiſe it for the more ready reception of the layers; then with your finger make a hollow or drill in the earth to receive the layer, which bend gently down horizontally into the opening, raiſing the top upright, ſo as to keep the gaſh or ſlit part of the layer open, and with one of the hooked ſticks peg down the body of the layer, to ſecure it in its proper place and poſition, ſtill preſerving the top erect, and the ſlit open, and draw the earth over it an inch or two, bringing it cloſe about the erect part of the ſhoot; and when all the ſhoots of each plant are thus layed, give directly ſome water to ſettle the earth cloſe, and the work is finiſhed, repeating the waterings often in dry weather; and in five or ſix weeks the layers will have formed good roots, when they ſhould be ſeparated with a knife from the old plants, and planted in beds or pots, as may be convenient, in the following manner.

*Taking off, and tranſplanting the Layers.*

The layers, as above obſerved, are generally well rooted in ſix weeks after laying, which you will obſerve by opening the earth a little, and examining the bottom, or root part, and if it has emitted plenty of fibres, they ſhould be taken off, and planted out ſeparately, to form diſtinct plants.

They

They muſt be cut or ſeparated with a knife from the old plant, gently raiſing them out of the earth with the point of a knife or trowel, ſo as to preſerve the fibres or roots of the layers as entire as poſſible; and when thus taken up, cut off the naked ſticky part at bottom cloſe to the root, and trim the tops of the leaves a little; they are then ready for planting, either into beds or pots, but rather into nurſery-beds of good earth, about ſix weeks, and then the fine ſorts may be potted; therefore chuſing a bed or border of rich light earth, let it be then neatly digged, and the ſurface raked ſmooth, and here plant the layers with a dibble, at ſix or eight inches diſtance, give directly a good watering, and repeat it, in dry weather, every day or two, for a week or a fortnight, when the plants will have taken freſh root, and begin to advance in growth.

In this bed let them take their growth till October, then thoſe of the fine varieties may be potted in ſmall pots (forty eights) for moving to occaſional ſhelter from hard froſts till ſpring, then tranſplanted into large pots to remain to flower; therefore, at the above-mentioned time in autumn, take up the layers of the prime ſorts from the nurſery-beds, with ſmall balls of earth about their roots, plant one in each ſmall pot, and give a moderate watering, and place them in a warm ſituation in the full air till November, then move them to occaſional ſhelter, as directed in their winter culture.

Some perſons plant the layers at once into large pots in autumn; but theſe are not ſo convenient to remove to ſhelter in winter, as ſmall pots, becauſe they take up much room in a frame, &c. beſides, by having the layers in ſmall pots all winter, when they receive hardly any growth, and tranſplanting them into large pots of freſh earth in ſpring, it proves very beneficial to the plants. See their *Spring Culture*.

The more common ſorts may either at the above time, in autumn, be tranſplanted into the borders or other compartments of the pleaſure-ground, where they are to remain to flower, or may be continued in the beds until ſpring; and then a due quantity may be diſpoſed in the borders, or retained in the ſame bed, for flowering, as may be convenient.

### *Their Winter Culture.*

In November the fine varieties in pots ſhould be moved to a ſunny ſheltered ſituation for the winter, and if placed in a frame, &c. to have occaſional protection from hard froſt, it will be of much advantage; therefore where there are any garden frames at liberty, the pots may be placed cloſe together therein, or if the bed is raiſed three, four, or ſix inches with light dry earth, ſand, or aſhes, and ſo plunge the pots in it to their rims, it will be a greater protection for their roots, covering them occaſionally with the glaſſes in hard froſts, &c. but for want of frames, a bed prepared as above, may be arched over with hoops, to be covered occaſionally with mats.

Under either of thoſe ſhelters the plants are to be covered with glaſſes or mats only in time of ſevere froſt and great ſnows; but muſt enjoy the full air in all open weathers, by having all covering entirely off, and a moderate froſt can no ways affect them, for if much covered, it would draw them up weak and tender. Do not however omit, in ſevere weather, to afford them the above ſhelter, which will preſerve the plants in greater health and vigour than if fully expoſed to all weathers during the winter.

Be careful alſo that the earth in none of the pots is rendered very wet by the hole at bottom being too cloſe ſtopped to detain the moiſture.

Thus continue your care of the potted plants till ſpring, and then ſhift them into large pots to remain to blow, as directed in their ſpring culture.

In reſpect to thoſe in the open beds, although they commonly ſtand the winter tolerably, yet if you have any ſpare frames, or the beds arched over, to be covered with mats or long dry litter in ſevere froſts, it will be of much advantage.

### *Their Spring Culture, ſhifting into larger Pots, &c.*

In the latter end of February, or ſome time in March, the layers in the ſmall pots, or ſuch as are in beds, and that you intend ſhall blow in pots, ſhould be tranſplanted with balls into the large pots, where they are to remain for flower.

The pots proper for their reception for flowering ſhould be ſixteens, but not leſs than twenty-fours; for they ſhould be nine or ten inches at leaſt in the clear at top, but if a foot the better, that there may be due room to lay the layers, at the proper ſeaſon, for a further increaſe, which is an eſſential point to be conſidered. The pots being ready, put ſome pieces of tile or oyſter ſhells over the holes

at bottom, and fill them half way with earth; then turn the plants out of the pots, &c. with the ball of earth about their roots, and after taking away a little of the earth around the ſides of the ball, place one plant in each of the large pots, filling up the vacancy round the ball with more freſh compoſt, bringing it alſo cloſe up about the body of the plant, which ſhould ſtand nearly as high as the rim of the pot; and finiſh each pot with a moderate watering.

Many perſons plant two plants in each large pot; but when there is only one, they flower ſtronger, make ſtronger ſhoots for layers, and there is more room to lay them.

The plants being thus potted, place them in a ſheltered ſunny ſituation in the full air, and in dry weather ſupply them with water twice or thrice a week, and here let them remain till they are conſiderably advanced, towards flowering, then the fine ſorts may be placed on the Carnation ſtage: where there is ſuch conveniencies obſerve as follow.

*Summer Culture, placing them on the Stage, and Management when in Bloom, &c.*

During dry warm weather continue the care of watering thoſe in pots every day or two. Likewiſe clear out all weeds, and at times lightly ſtir the ſurface to prevent the earth from binding, which will be beneficial to the plants, and preſerve an air of neatneſs.

In May and June the flower-ſtems of the plants will advance a-pace, when ſticks ſhould be placed for their ſupport, which ſhould be two feet and half, or a yard long, either round or ſquare, but perfectly ſtraight and tapering from the bottom; ſuch as are ſold about London at the lath-renders and turners, for nine-pence or a ſhilling per dozen; ſharpening the lower end, thruſt one down by every plant, to which tye the flower-ſtems in a neat manner, which repeat at different times, according as they advance in height.

In June or beginning of July the plants will be conſiderably advanced towards flowering, when thoſe intended for the ſtage ſhould be placed thereon, both to be out of the way of creeping inſects, particularly ear-wigs, which, as before obſerved, eat the petals off at their baſe, to the deſtruction of the flowers; ſo to prevent their depredation, the poſts or ſupporters of the ſtage ſhould be ſurrounded at bottom by ſmall ciſterns of water, as hereafter directed, that the vermin cannot come at the poſts, to creep up to the flowers; and that by placing the plants on a ſtage, having the platform eighteen inches or two feet high, the flowers are viewed to more advantage; and if there is erected an awning over the top, ſupported four feet above the platform, the flowers being hereby ſcreened from the vehement heat of the mid-day ſun, and defended from heavy rains, are continued much longer in beauty.

Some Carnation ſtages are conſtructed upon very elegant plans, both to render them uſeful and ornamental.

But as to the general conſtruction of a common Carnation ſtage, it is formed entirely of ſlight timber-work, thus—A boarded platform is erected, at eighteen inches or two feet height, formed by two ranges of planks, to contain two rows of pots lengthways, proportionable to the number intended to be placed thereon; and which is ſupported on poſts, ranged either in one row along under the middle of the platform, or in two ranges, one on each ſide; and over the top is erected a roof of open work, five or ſix feet high, to be covered with painted canvas, &c. for the protection of the flowers, ſupported either by a range of neat poſts on each ſide, or by one row, ranging along the middle between the planks of the platform, which is the moſt eligible; the roof may be formed either archways, or like the ridge of a houſe, having the arches or ſpars about a foot aſunder, and ſtiffened by thin ſlips of deal carried acroſs them the whole length of the ſtage; and the roof thus formed may be covered either with coarſe canvas painted white, or ſtrong brown paper painted the ſame colour with white lead, or with ſtrong white paper bruſhed over with linſeed-oil to render it proof againſt wet, or in default of either of theſe, may cover it with neat garden-mats, lengthways, either of which being deſigned only juſt to ſcreen the flowers from the ſcorching ſun and great rains, that their beauty may be continued as long as poſſible.

All the wood-work of the ſtage ſhould be painted white, both to preſerve it from the weather, and give it a more lively appearance.

In conſtructing Carnation ſtages, ſome are ſo curious as to contrive ſticks for the ſupport of the flower-ſtalks, fixed to the work of the ſtage, by means of ſmall neat rails carried along lengthways the ſtage, juſt over the place where each row of pots ſtand, and from which rails upright ſticks, half an inch thick,

thick, are carried to another ſuch rail above, placing them at ſuch diſtances, that there be two to each pot, and ſo train the flower-ſtems up to the outſide of the ſticks.

With reſpect to the ciſterns of water above mentioned, to ſurround the ſupporters of the ſtage, they are formed by earthen or leaden pans, about fifteen inches wide, and three or four deep, having a hollow or vacancy in the middle ſix inches wide, like a ſocket, to receive the poſts, and is formed by a raiſed rim in the middle, equal in height to that of the circumference; and the hollow or ſocket ſo formed is to receive the bottom of the poſts quite through to the ground, and the ſpace between the outer and inner rim is filled with water; ſo that each poſt ſtanding in the middle of ſuch a ciſtern, ſufficiently guards againſt creeping inſects, for they will not attempt to croſs the water.

Theſe ciſterns may be had at any of the potters that make garden-pots; and if you chooſe them of lead, every plumber knows their conſtruction.

But as making the above deſcribed Carnation ſtage may not be convenient to every one, I ſhall deſcribe one of a more cheap and eaſy conſtruction. Provide ſome flat earthen pans about fifteen or eighteen inches diameter, and three or four deep, which place by pairs oppoſite two feet apart, and ſix or eight feet between each pair lengthways; and in each of theſe pans, whelm a large garden pot bottom upward, and acroſs each pair of pots lay a flat piece of timber, two feet ſix inches long, and two or three inches thick; then having long planks, lay theſe acroſs the timbers lengthways, in two rows, and your ſtage is formed, then place two rows of pots upon the planks, and fill the pans with water, to keep off inſects.

For want of a covered ſtage to ſcreen the flowers, you may contrive a kind of ſmall umbellas or round-ſpreading caps, either of tin or ſtrong paper or canvas, nine or ten inches diameter, one for each plant, having a ſocket in the middle to receive the tops of the ſupport-ſtick; thoſe umbrellas which are formed of tin are the beſt, and may be had at the tin-ware ſhops; but if you make them of paper or canvas, firſt form little round frames, having the rim formed with ſlips of lead, wire, cane, &c. the above width, with croſs ſlips of the ſame materials, contriving a ſocket of lead or tin in the middle for the ſupport ſtick to go quite through, as juſt obſerved; and upon theſe frames paſte or ſow ſome ſtrong thick paper or canvas, which paint with oil-colour, that they may ſtand the weather; either of which covers are placed over the flowers by running the ſupport ſtick up through the hole or ſocket in the middle, and reſting the cap upon a piece of wire put acroſs the ſtick, at ſuch height from the flower as to ſcreen it effectually from the ſun and rains.

Give attention to continue to tye up neatly the flower ſtalks of the plants in general, as they advance in ſtature. When they are arrived at their full height, the curious in Carnations ſupport them erect at top with wires, having a ſmall eye or ring at one end, for the reception of the flower ſtalk, ſo put the other end into holes made in the ſupport-ſticks; theſe wires ſhould be five or ſix inches long, and ſeveral holes are made in the upper part of the ſticks, the firſt at the height of the bottom of the flower-pod, the others above that, an inch or two diſtant, and place the wires in the holes lower or higher, that the eye or ring may be juſt even with the baſe of the calix, to ſupport the flower in an upright poſition; and by drawing the wire leſs or more out, the flower is preſerved at any diſtance from the ſupport as ſhall ſeem neceſſary, to give it proper room to expand; and if two or three of the like wires are placed alſo in the lower parts of the ſupport-ſticks, placing the ſtem of the flowers alſo in the eye of the wires, all the tyings of baſs, &c. may be cut away.

To have as large flowers as poſſible, curious floriſts clear off all ſide-ſhoots from the flower-ſtem, ſuffering only the main or top buds to remain to flower.

When the flowers begin to open, attendance ſhould be given to aſſiſt the fine varieties, to promote their regular expanſion, particularly the large burſter kinds, they being apt to burſt open on one ſide, and, unleſs aſſiſted by a little art, the petals will break out of compaſs, and the flower become very irregular; therefore attending every day at that period, obſerve, as ſoon as the calix begins to break, to cut it a little open at two other places in the indentings at top, with narrow-pointed ſciſſars, that the openings be at equal diſtances, and hereby the more regular expanſion of the petals will be promoted; obſerving, if one ſide of any flower comes out faſter than another, to turn the pot about, that the other

ſide of the flower be next the ſun, which will alſo greatly aſſiſt the more regular expanſion of the flower.

Likewiſe when intended to blow any particular fine flowers as large and ſpreading as poſſible, floriſts place ſpreading paper collars round the bottom of the flowers, on which to ſpread the petals to their utmoſt expanſion; theſe collars are made of ſtiff white paper, cut circular, about three or four inches over, having a hole in the middle to receive the bottom of the flower, and one ſide cut open to admit it; which is to be placed round the bottom of the petals within ſide of the calix, the leaves of which are made to ſpread flat for its ſupport; and then ſpread or draw out the petals upon the collar, to their full width and extent, the longeſt ones undermoſt, and the next longeſt upon theſe, and ſo of the reſt quite to the middle, obſerving that the collar muſt no where appear wider than the flower; thus a Carnation may be rendered very large and handſome; but we do not recommend the practice as abſolutely neceſſary, only mention it as the practice of thoſe who have much leiſure time, and who take a particular pleaſure in exhibiting very large Carnations; and indeed, a carnation that expands regular in their natural way, whether whole-blower or burſter, although they do not appear ſo large as the collared flowers, yet I ſhould think they muſt appear more natural and beautiful; and even the largeſt burſters may be made to blow very regular with a little attendance, juſt to ſlit the calix, as hath been directed, when they begin to burſt.

But as the whole-blowers always blow regular without any trouble of opening the calix, and although not ſo large as the burſters, yet have great beauty, and are the moſt proper for general culture, for thoſe who have much other buſineſs to mind.

Continue the care of watering the pots, which in dry hot weather will be neceſſary every day, being eſſential to promote the ſize of the flowers, and increaſe the ſtrength of the ſhoots of the plants at bottom, for layers.

And as in June and July the layers will be arrived at proper growth for laying, ſhould alſo be layed to continue your increaſe of the approved varieties, and ſo continue laying the ſhoots of each year's growth at the above ſeaſon, managing them always as before directed.

As to the border Carnations, i. e. ſuch as you intend ſhall flower in borders or beds in the full ground, any of the varieties may be employed, and their propagation both by ſeed and layers is the ſame as already directed; the ſeaſon for tranſplanting them into the places of their final deſtination for flowering, is alſo either in autumn or ſpring, that is, October or beginning of November for the autumn planting, and for that of the ſpring, any time in March, or firſt fortnight in April; removing them with little balls about their roots, planting them about two feet from the edge of the border; and as to culture, it is principally tying up the flower-ſtalks as they advance in ſtature, and to make layers of all the approved ſorts annually, in June or July, for propagation.

*General Obſervations.*

I would juſt hint here, of Carnations in general, whether for pots, or as border-flowers, that their propagation and general culture is always the ſame as already directed, under the two reſpective heads of Propagation by Seed, and by Layers: raiſed and treated according to theſe directions, becomes a good plant the ſame ſeaſon, fit for tranſplanting finally in autumn or ſpring following, either into pots or the open borders, and they will flower in the utmoſt perfection the ſucceeding ſummer.

And that the general ſeaſon for planting out finally all ſorts, ſeedlings and layers from the nurſery-beds, &c. into the places where you deſign they ſhall flower, either in pots or the full ground, is October or beginning of November, or in ſpring any time from the latter end of February to the beginning or middle of April, removing them with ſmall balls about their roots, plant them ſingly, that is, one in a place, and always finiſh with a watering to ſettle the earth cloſe about the roots.

Always in May and June give attendance to tye up the flower-ſtalks to ſupport-ſticks, repeating it occaſionally; for this looks neat to the eye, and promotes the ſize and regularity of the flowers.

Every ſpring it may be proper to ſow ſome ſeed to obtain varieties.

Every ſummer, in June or July, make layers for increaſe of all the approved double ſorts, whether Clove or Carnation, of the Flake, Bizarre, Piquette, or Painted Lady kinds.

Note, they may alſo be propagated by cuttings and pipings, as directed in the Pro-

propagation of Pinks, but theſe are not ſo ſucceſsful in general as layers.

As to the old roots, having a good increaſe of new young plants by layers, you may either eradicate them, or uſe them in different parts of the pleaſure-ground in vacant ſpaces of large borders, &c. for being perennial, they will endure ſeveral years, though the new plants always afford the largeſt and fineſt flowers.

*Saving the Seed.*

All the varieties of Carnations, both ſingle and double flowered plants, produce abundance of ſeed, which ripen freely in Auguſt and September.

But to have the greater chance of obtaining ſeeds for raiſing fine new varieties, you ſhould mark ſome of the fineſt flowers when in bloom, and all thoſe of bad colours, or of other bad properties, ſhould be removed to prevent any admixture of the farina. For the ſame reaſon, it is alſo of importance for the purpoſe of ſeed, to keep the flakes, bizarres, piquettes, &c. as far diſtant as poſſible, whereby each of theſe ſorts may, even from ſeed, be preſerved tolerably permanent, though each in itſelf profuſe in many varieties of its own kind.

It is alſo worth obſerving, that ſeedling plants are generally more prolific in good ſeed, than ſuch as have been long encreaſed from year to year by layers.

The ripening of the ſeeds ſhould be attended in Auguſt and September, to gather the pods in due time, as they ripen in dry weather, which ſpread on paper to dry, then rub them out and put them up in dry papers till ſowing-time in ſpring.

*Second Head of Dianthus.*

DIANTHUS Compriſing thoſe kinds of Dianthus commonly denominated Pinks.

The principal ſpecies of the Pink kind are diſtinguiſhable from the Carnation tribe of the firſt claſs, by the ſhoots and leaves being conſiderably ſhorter, ſmaller, more numerous, and tufted; and the flower-ſtalks ſhorter, the flowers ſmaller, and more crenated.—All of which ſpecies are hardy herbaceous fibrous-rooted plants of the flowery tribe; though there are but two ſpecies eſteemed for general culture, one the Common Pink, a perennial; the other, the Chineſe or Indian Pink, an annual, both of which, admitting of ſeveral eminent varieties of great merit for the ornament of the pleaſure garden.

There are however about four ſpecies, which may be admitted into the flower garden, three perennial and one annual.

Claſs and order the ſame as the Carnation. See the *Firſt Head.*

The firſt three are perennials, viz.

1 DIANTHUS *Deltoidos.*

*The Common Pink.*] Dianthus with numerous ſhort leafy ſhoots crowning the root, in a tufted head cloſe to the ground, cloſely garniſhed with ſmall narrow leaves, and from the ends of the ſhoots many erect flower ſtalks from about ſix to fifteen inches high, terminated by ſolitary flowers, having lanceolate double ſcales to the calix, and crenated petals, and with ſingle and double flowers of different colours, and variegations in the varieties.

This ſpecies and its following varieties are the ſorts of Pinks the moſt commonly known and cultivated, all of which are perennial.

*The moſt material varieties are,*

*Common Red Pink.*—Produces flower-ſtalks eight or ten inches high, and ſmall red flowers.

*Damaſk Pink.*—Produces flower-ſtalks ſix or eight inches high, and reddiſh purple flowers.

*White Pink.*—Producing flower-ſtalks eight or ten inches high, and very white flowers.

*White fringed Pink.*—Produces flower-ſtalks ſix or eight inches high, and pure white flowers, having the edges of the petals conſiderably jagged or fringed.

*Pheaſants-eye Pink.*]—Producing firm flower-ſtalks eight or ten inches high, and large whiteiſh and bluſh-coloured flowers, having a dark purple ſpot or eye in the middle, hence called Pheaſants-eye Pink.

Of this ſort there are many varieties obtained from ſeed, all of them generally retaining the purple eye in the middle, but differing from each other in ſize, doubleneſs, colour, and the ſize and colour of the eye, &c. So that the different intermediate varieties have names according to the fancy of the perſon who firſt raiſed each new variety. And of the different varieties, there are whole blowers and burſters, the latter are generally very large, but the whole-blowing flowers are preferable for the regularity of growth.

*Red Cob Pink.*—Producing flower-ſtalks twelve or fifteen inches high, and large bright red flowers.

Of each of the above varieties of this ſpecies *Dianthus Deltoides*, there are ſingle and double flowers, the ſingles are but little regarded,

garded, as enough of them may be obtained from ſeed, and from which alſo the doubles were firſt obtained; but the doubles being large multipetalous and more beautiful, are the only ſorts worth general culture, and which being once obtained, they may be continued and encreaſed abundantly by layers, ſlips, cuttings, and pipings. See their *Propagation*.

As to the flowering ſeaſon of all the varieties, ſome of the ſmall ſorts, ſuch as the damaſk, and white ſhaggy Pink, often flower in May, or early in June, which are ſucceeded by the others, continuing in ſucceſſion till July, all of which furniſh plenty of ſeed in autumn.

[2]DIANTHUS *Virgineus*.

*Maiden Pink, commonly called Matted Pink.*] Dianthus with numerous low trailing leafy ſhoots, crowning the root in a matted tuft, cloſe to the ground, garniſhed with ſhort, awl-ſhaped deep green graſſy leaves; and many erect flower-ſtalks ſix or eight inches high, terminated each by one red flower having very ſhort calycinal ſcales, and crenated petals.

*Variety.*] With fleſh coloured flowers.

[3]DIANTHUS *Glaucus*.

*Glaucous or Grey-leaſed Mountain Pink.*] Dianthus with many low leafy ſhoots crowning the root in a cluſter cloſe to the ground; very ſhort narrow grey coloured leaves, and many erect branchy flower-ſtalks eight or ten inches high, terminated by large white flowers, having a purple circle in the bottom; and with four lanceolate calycinal ſcales, and crenated petals.

*Variety.*] With double flowers.

## ANNUAL.

[4]DIANTHUS *Chinenſis*.

*Chineſe, or Indian Pink.*] Dianthus with upright firm flower-ſtalks, branching erectly on every ſide, a foot or fifteen inches high, and all the branches terminated by ſolitary flowers; having awl-ſhaped ſpreading calycinal ſcales equalling the tube, and indented petals; and with ſingle and double flowers of different colours, and variegations in the varieties —Flowering from July till November.

*Varieties are.*] With bright red ſingle and double flowers—with purple ſingle and double flowers—white ſingle and double flowers—variegated ſingle and double flowers; of each of which are many intermediate varieties in reſpect to the ſhades, and diſpoſition of the colourings, eſpecially of the variegated kinds, which are in general lively and elegant; the doubles in particular are ſingularly beautiful, being large and very full of petals to the very centre, all of which varieties may be conſidered both as annual and biennial, for they riſing from ſeed in ſpring, flower the ſame year in ſummer, and commonly periſh in winter, eſpecially in moiſt ſoils, but if planted in dry warm ground, ſheltered from ſevere froſt, the roots will continue two years, and flower ſtrongeſt the ſecond ſeaſon of their bloom: they all flower abundantly from July till the beginning of winter, furniſhing plenty of ſeed in autumn, from which the plants are raiſed plentifully in ſpring, either in the full grounds or in hot-beds, to bring them more forward.

All the flowers of the above four ſpecies and their varieties, are in their ſingle ſtate compoſed of five petals, but in their compound or double ſtate, the petals are multiplied, and the firſt and fourth ſpecies are very prolific in double varieties, which are often large and very full of petals, continued in many ſeries to the centre; and both ſingles and doubles ariſe from ſeed, but often ten or twenty or more ſingles to one double.

They flower in June and July, the annual ſort continues till autumn, and all of them produce ſeed in plenty.

*Uſe in Gardens, &c. of all the Sorts.*

All the above four ſpecies of the Pink tribe, and reſpective varieties conſidered, as hardy flowering plants are proper furniture for the compartments of the pleaſure ground; but the firſt ſpecies, *Dianthus Deltoides* and varieties, have ſuperior merit both for the beauty and fragrance of their flowers, and are the ſorts in greateſt eſtimation for general culture, as plants of ornament; and as each plant of any tolerable ſize produces numerous flower-ſtalks, all terminated by flowers, renders them choice furniture for the common flower-borders, or to embelliſh the vacant ſpaces in the fronts of ſmall ſhrubbery clumps. The ſecond and third ſpecies are alſo retained in many gardens, to encreaſe the variety in the collection of flowering perennials. And the fourth ſpecies, *Dianthus Chinenſis*, has great merit, not only for the livelineſs of their beautiful flowers, but alſo for the long continuance of their bloom, which in the ſame plant is often continued in plentiful ſucceſſion three or four months, but have no fragrance.

Obſerve that, as all the perennial Pinks, being both of a tufty and ſpreading growth, and

and produce many flower-ſtalks, they ſhould be diſpoſed ſingly, only one plant in a place; but the annual ſort being different, it is rather proper to diſpoſe them in patches of three or four plants in each.

Any of the ſorts may alſo be cultivated in pots occaſionally, to place in fore-courts, or to adorn any other principal compartment.

Sometimes the Common Pink and varieties are employed to form edgings to beds or borders, but as in one year they are apt to ſpread greatly out of compaſs, and become irregular, they are not well adapted for that uſe.—However, if they are uſed for that purpoſe, the edging ſhould be cut in on each ſide once or twice a year, with garden ſheers.

Great quantities of the Common Pink and varieties are, when in bloom, brought to the London markets for ſale, each with a ſmall ball of earth about their roots, which ſell from one to two or three ſhillings per dozen of plants; but when in pots, double or treble that price; or if they are forced in hot-beds for an early bloom, as mentioned before, they fetch conſiderably more.

About London great quantities of the double varieties of the Common Pink are forced by aid of artificial heat, for an early bloom in February, March, and April, for the ſupply of Covent-Garden market; the pheaſant-eye kinds are moſt commonly uſed, but any of the ſorts will ſucceed: they muſt be potted, and in January, February, or March, placed either in the hot-houſe, or in a forcing-frame, worked either by bark or dung heat. See FORCING FRAME. The plants thus forwarded ſell from about a ſhilling to half a crown per pot, according to the earlineſs of the ſeaſon, and merit of the flowers.

*Propagation, &c. of the Perennial Sorts.*

The firſt, ſecond, and third ſpecies, are propagated by ſeed, layers, ſlips, cuttings, and pipings.

By Seed.—Great numbers of plants may be raiſed with the utmoſt facility by ſeed, in a bed or border of common earth in ſpring, which will all flower the year following, and among which there will probably be many double flowers, and ſome new varieties, particularly of the firſt ſort, Common Pink.—The proper ſeaſon for ſowing is, March and April. Chuſe a bed of rich light earth, dig it neatly, and form the ſurface even, then ſow the ſeed and rake it in; or may practiſe as directed for the Carnations; the plants will appear in a month or five weeks, which, in June or July, when two or three inches high, plant out into nurſery beds till October or ſpring following, and then to be tranſplanted with balls into the places where they are to flower, or they may remain in the beds for flowering, as obſerved of the Carnation ſeedlings. When they ſhew bloom, the ſingles may be drawn out to give room for the double kinds, which you may continue and encreaſe abundantly, by layers, ſlips, cuttings, &c. and all the plants ſo raiſed, produce flowers, having all the properties of thoſe of the mother plant.

By Layers.—The ſame method is to be obſerved for thoſe as for the Carnations, and June, July, and beginning of Auguſt is the time to perform this work, or managing them in every reſpect as the Carnation layers: or if in ſpring, ſome large plants which have ſpread conſiderably, have all their ſhoots covered with earth an inch or two deep, without taking pains to ſlit or tongue them, as in laying Carnations, many of them will emit fibres and be well rooted, and fit to tranſplant in autumn, each a diſtinct plant.

By Slips.—In ſpring, any old plants of the approved varieties may be encreaſed by dividing them into many ſlips, either by ſlipping off the younger ſhoots from the ſides of the main ones, which, though deſtitute of roots, many of them will readily emit fibres and grow; or may divide, or ſlip the plants quite down to the roots, where practicable, ſo as to preſerve as many fibres to each ſlip as poſſible; but ſlips by either method, if done in February, March, or April, will readily ſucceed, and form good plants by the end of ſummer, obſerving, that the ſhort buſhy plants are more eligible for ſlipping, than ſuch that are long and ſtraggling; and ſlips from about three or four, to ſix or eight inches long, will ſucceed. Having therefore ſlipped a proper quantity for planting, let them be planted in a bed or border of good earth, ſix inches aſunder, putting them down almoſt to their tops, give them water directly, and repeat it occaſionally, in dry weather; they readily take root, grow freely, and form good plants by Michaelmas, when, or in ſpring after, they may be tranſplanted with balls, where you deſign them to flower.

By Cuttings.—June and July is the beſt time for this work, when the young ſhoots of the year will be advanced a proper length to form cuttings of two or three inches long,

which planted will readily grow, and form good plants the ſame year.

Obſerve therefore, when the ſhoots of the ſame year's growth are of a proper length, and proportionably firm, not the long ſlender ones, but thoſe of ſomewhat robuſt growth; and of which take off a proper quantity four or five inches long, then trim off all the lower leaves, and cut thoſe at top pretty ſhort, and then at about two or three inches from the top, cut them clean through a joint horizontally, caſting the lower part away, and reſerve the top for planting, which, if two or three inches long, is a proper cutting; being thus prepared, then having ſome rich light earth broken perfectly fine, either in a bed, border, or in large pots, making the ſurface ſmooth, plant the cuttings as follows: take them one by one by their tops, and thruſt the lower end into the earth they will readily make way for themſelves; ſo putting them down full half way, and an inch or two aſunder, and give directly a good watering out of a pot with the roſe on, they ſhould then be covered air-tight with bell or hand glaſſes, which will greatly facilitate their rooting; nor need they be taken off till the cuttings are ſo far rooted as to begin to grow, nor need they be much ſhaded; and the watering, which muſt be often repeated, may be applied around the outſide of the glaſſes, a ſufficiency of which will ſoak to the mold within for the benefit of the cuttings; but for want of glaſſes they may be ſhaded in the heat of the day with mats, and frequently watered.

They will thus be rooted in a month or ſix weeks, aud advance faſt in growth, and ſhould then be fully expoſed; and, when well rooted and advanced conſiderably at top, ſhould be tranſplanted, gently raiſing them out of the earth with their roots as entire as poſſible, and prick them in a bed of good earth five or ſix inches apart, to remain till autumn, or ſpring following; then may be removed to the places allotted for them to flower.

By the above method the London gardeners generally propagate all the choice varieties of double pinks, which is not only the moſt certain and expeditious, but form much better plants than thoſe by ſlips; and to keep up their ſtock, always propagate vaſt quantities every ſummer by this method: an expert hand will plant a thouſand per day, and not one in fifty miſcarry.

By Pipings.—This is nearly the ſame as by Cuttings, only, that inſtead of cutting off at a joint, take the head of the ſhoot in betwixt the finger and thumb, and draw it aſunder at the joint, by which it often comes out of its ſocket as it were, leaving a hollow like a pipe, hence it is called Piping; trim the bottom of each even to the joint, they are then to be planted and managed exactly as directed above for the cuttings.

*Propagation, &c. of the Annual Sort.*

*The Dianthus Chinenſis.*—Being rather of the Annual tribe, or at moſt biennial, is always raiſed from ſeed annually in ſpring, tho' if the plants have a dry warm ſoil in winter, they will abide two years, and produce ſtronger flower-ſtems, more numerous, and larger flowers than the ſame year's ſeedlings.

As the plants however, are eaſily raiſed in great plenty from ſeed, and as they are rather apt to go off in winter, a freſh ſupply ſhould be annually raiſed; the ſeed grows freely in a bed of natural earth, ſown any time in April, or beginning of May, either on the ſurface, and raked in, or firſt rake the ground ſmooth, ſow the ſeed and ſift earth over, to a quarter of an inch deep, or ſow it in drills that depth; but to bring the plants as forward as poſſible, you may ſow the ſeed in a hot-bed, with other annuals of ſimilar quality, ſuch as African marigold, China aſter, &c. See ANNUAL PLANTS.—And in May or June, when the plants of either method of ſowing are a month old, about two or three inches high, prick them out from the ſeed-bed into a bed of good rich earth, in rows ſix inches aſunder, giving water, and occaſional ſhade till rooted; and after having a month's growth here, they will be of a proper ſize for final tranſplantation, taking them up with balls, and planting them into the different compartments of the pleaſure-ground, in patches of three or four plants in each, in which they will appear more conſpicuous in flower than if diſpoſed ſingly.

*Sowing the Seeds of all the Sorts.*

All the ſorts of Pinks of this claſs afford ſeed plentifully in Auguſt and September, which ſhould then be gathered in the pods in dry weather, ſpead to dry and harden on papers, then rubbed out and put up for the ſpring ſervice.

*Third Head of Dianthus.*

DIANTHUS, &c.—Comprehending thoſe ſorts of Dianthus commonly called Sweet-Williams.

This claſs compriſes but one ſpecies, which admits of numerous elegant varieties, all hardy, herbaceous, fibrous-rooted, flowery perennials, diſtinguiſhable from the two former claſſes of *Dianthus*, by having larger ſhoots, much broader leaves, and, by the flowers growing all at top of the ſtalks in aggregate cluſters.

Claſs, order, and characters the ſame as the other ſpecies of *Dianthus*, See the *Firſt Head.*

The ſpecies is,

DIANTHUS *Barbatus.*

*Bearded Dianthus, commonly called Sweet-William.*]—Dianthus with many thick leafy ſhoots crowning the root in a cluſter cloſe to the ground, garniſhed with ſpear-ſhaped evergreen leaves, from half an inch to two inches broad; and upright firm flower-ſtems branching erectly two or three feet high, having all the branches and main ſtem crowned by numerous flowers in aggregate cluſters of different colours, and variegations in the varieties.

The varieties may be divided in two claſſes. Narrow-leaved and broad-leaved kinds, the narrow-leaved ſorts being remarkable for being the moſt productive of variegated flowers, and many doubles.

*Varieties are,*

*Narrow-leaved kind.*]—With narrow leaves and deep red flowers—With pale red flowers—Pale red, and fleſh-coloured flowers—Purpliſh white eyed flowers—Snow-white flowers—White and fleſh-coloured flowers—White and purple flowers—White ſpotted flowers—Red flowers and white borders, called Painted Lady Sweet William; and with many other intermediate ſhades of colours and variegations, and which frequently vary in the flowers of the ſame aggregate; there are alſo ſingle and double flowers of each variety. Among the doubles of this claſs of narrow leaves, is that ſort called the Mule, having a bright red double flower in ſmalliſh aggregates, ſaid to have been accidentally produced from the ſeed of a Carnation, impregnated by the effluvia of a Sweet William, hence is called the Mule.

*Broad-leaved kinds.*]—With broad leaves and tall deep red flowers—Tall fleſh-coloured flowers—Pure white flowers—White dotted flowers—Striped leaves and red flowers—Large double roſe-coloured ſweet-ſcented flowers—Large double deep purpliſh burſter flowers—Double variegated flowers.

All the varieties of both claſſes are hardy herbaceous, evergreen perennials, riſing the firſt year with a large buſhy tuft of leafy ſhoots, continuing green the year round, and the ſecond year ſhoot up flower ſtems, producing flowers in June and July, ſucceeded by abundance of ſeed in autumn.

The corolla, in all theſe varieties of each claſs is, in its ſingle characteriſtic ſtate, compoſed each of five petals, but in the double flowers it is large and multipetalous, and both ſingle and double are obtained from ſeed; though probably ten, twenty, or more ſingles to one double, and the narrow-leaſed kinds are generally the moſt productive of double, which are more commonly variegated than of plain red or white colours.

But both ſingles and doubles are extremely elegant, and in a great degree ornamental garden flowers, which terminating the ſtalks and branches in large cluſters, like umbels, continuing ſix weeks in bloom, but have no fragrance; ſo that their merit conſiſts entirely in their ornamental appearance for the decoration of the borders, and other parts of the pleaſure-ground, in which they are exceedingly conſpicuous and grand; and as they are all ſo hardy as to proſper in any common ſoil of a garden, and may be raiſed abundantly from ſeed in the full ground, a good ſtock of them ſhould always be maintained by an annual ſowing, and the fine doubles by layers, &c. See their *Propagation.*

Some of the large double ſorts may alſo be cultivated in pots, to place occaſionally, to adorn fore-courts, or other principal diſtricts of a garden.

The plants although in general of ſeveral years duration, yet, after the firſt year of flowering, the ſhoots generally become long, ſtraggling, and of unſightly, dwindling growth, ſo that a ſupply ſhould be raiſed every year from ſeed, or layers, for the one year-old plants are always cloſe and buſhy, and flower much ſtronger than thoſe older ſtanding; and the following is their method of propagation:

*Their Propagation.*

They are propagated by ſeed, layers, and ſlips, all of which is eaſily effected in the full ground.

By Seed.—March and April is the ſeaſon for ſowing, and the ſeed is ſold cheap enough at all the nurſeries and ſeed-ſhops: ſow it in a bed or border of light earth broaſt-caſt, and rake it in; in a fortnight after the plants will

come up, which in June or July ſhould be tranſplanted into nurſery-beds of common earth, in rows ſix or eight inches diſtant, to remain until autumn or ſpring following, then taken up with balls about their roots, and planted in the places where they are to flower.

By this method great quantities of the plants are raiſed in gardens about London for ſale, which are generally marketable juſt as they begin to ſhew bloom, and which, of the ſingle kinds, fetch but from ſix-pence to a ſhilling per dozen of plants; but often more than that for one plant of the doubles.

By Layers.—June and July is the proper ſeaſon, and the ſame method is to be obſerved in every reſpect as for the carnations, which ſee, ſo it will be unneceſſary to repeat it here. This is the only method of propagation to continue the fine double-flowered varieties, which being layed, give frequent waterings in dry weather, and they will be well rooted in ſix or ſeven weeks; then ſhould be ſeparated from the old plant, and planted in a bed of light ſoil; and in October ſome of them ſhould be potted, to move to occaſional ſhelter from froſt, for although the doubles are almoſt as hardy as the ſingle kind, yet being more choice it is neceſſary always to have ſome of the fineſt in pots, that they may have protection in ſevere winter weather, obſerving the ſame as for the choice carnations.

By Slips.—February, March, April, and October, is the time for this work, obſerving, if it is to be performed upon the year-old plants, they muſt be ſlipped quite down to the roots, ſo as to have fibres to each ſlip, then may plant them at once where they are to flower; but theſe never make ſo good plants as ſeedlings and as layers, nor do they generally flower ſo ſtrong.

*Saving the Seed.*

The Sweet-williams are remarkably prolific in ſeed, particularly all ſingle varieties, and from which both ſingle and double ſorts are obtained.

If you would cultivate only the fineſt varieties, the flowers which have the moſt beautiful colours, both of the plain and variegated kinds, ſhould, when in full bloom, be marked from which to ſave ſeed: if any ordinary ſorts grow near them, let them be removed to prevent an admixture or emiſſion of the effluvia or male-powder in the flowers of the choſen ſorts, which might occaſion a great variation, for by obſerving this you may continue ſome of the varieties tolerably permanent.

Let the branches of ſeed be gathered in dry weather, and after lying a few days in the ſun to dry and harden, beat it out, and put it up in papers, &c. till ſpring, for ſowing.

DIBBLE *or* DIBBER. A ſimple but uſeful implement of gardening, uſed for planting out all ſorts of young plants, &c.

The beſt ſort of Dibble is that made of the tree of an old ſpade, having the head or top handle entire, and the ſhank twelve or fifteen inches long, made gradually tapering to a point at the lower end, and which to be perfectly complete ſhould be ſhod with a thin ſocket of iron eight or ten inches in length, made alſo tapering to a point at bottom; for an iron-ſhod dibble makes the holes for the reception of plants much eaſier, cleaner, without clogging, and more expeditiouſly than entirely of wood, which is apt to clog with earth, and greatly retard the work of planting.

The above ſort of dibble is proper for planting out almoſt all ſorts of young plants, particularly the fibrous-rooted kinds, and all ſorts of cuttings, &c.

But beſides the above kind of narrow-pointed dibble, for planting out young plants, &c. I ſhould alſo adviſe to have a blunt-pointed one for planting large kinds of ſeeds, and bulbous roots, ſuch as broad beans, potatoes, large kinds of nuts, &c. and the bulbs of crocus, narciſſus, tulips, and other bulbous kinds, that by being rounded at the end, makes a hole to receive the above ſorts of large ſeed and roots plump to the bottom; whereas the narrow-pointed dibble makes the hole deeper than it is capable of admitting them, ſo that there will be a vacancy under the ſeed or root, in which water might ſtand to their prejudice, eſpecially in winter; beſides, when the ſeed or root goes clean to the bottom, it is certainly more effectual to its free growth.

It may indeed be advanced, that the narrow-pointed dibble will anſwer the ſame purpoſe, by ſtriking a little earth into the hole to fill up the narrow part at bottom, previous to planting the ſeed or root, but this in a hurry may often be omitted, and takes up more time: but the blunt-ended dibble makes the hole at once to admit the ſeed or root always plump to the bottom.

But as to planting bulbous roots by dibble, though

though often practiſed, yet if they are to be planted together in beds, I would rather adviſe drilling them in, that is, draw drills three or four inches deep with an hoe, ſo place the roots plump bottom downward in the drills, and earth them over. See the reſpective articles of HYACINTH, NARCISSUS, DRILLS, &c.

DICTAMNUS, White Dittany, or *Fraxinella.*

It conſiſts of one hardy, herbaceous, flowery perennial, riſing two or three feet high, crowned by ſpikes of pentapetalous flowers.

Claſs and order, *Decandria Monogynia.*

*Characters.*] CALIX, five ſmall, oblong, pointed leaves. COROLLA, five irregular petals. STAMINA, ten riſing filaments, and four-cornered antheræ. PISTILLUM, a pentagonous germen, ſhort incurved ſtyle, and acute ſtigma. PERICARPIUM, a quinquelocular bivalvular capſule, and roundiſh hard ſeeds.

The ſpecies is,

DICTAMNUS *Albus.*

*White Dittany, commonly called Fraxinella.*] Dictamnus, with thick, penetrating, perennial roots, collected into a head at top, ſending up erect ſtalks annually two or three feet high, garniſhed with pinnated alternate leaves, of three or four pair of oblong ſtiff lobes, terminated by an odd one, and the ſtalks crowned by long, pyramidal, looſe ſpikes of flowers.

*Varieties of this are*] With white flowers—with red flowers, ſtriped with purple—with ſhort ſpikes of flowers.

The flowers of all the varieties have five unequal petals, i. e. two of them turning upward, two oblique on the ſides, and one turning downward, appearing in the latter end of May and in June, ſucceeded by ripe ſeeds in September.

They are very ornamental garden flowers, ſo merit a place in every collection of flowery perennials, and they ſucceed in any of the common borders.

The whole plant imparts a balſamic odour, when bruiſed, and the roots are uſed in medicine.

All the varieties are propagated by ſeeds, in a bed or border of common earth, ſowed in autumn or ſpring; but the autumn ſowing, i. e. in September or October, generally riſe ſtrong the ſpring following, which in autumn after, when the leaves decay, ſhould be planted in a bed or border ſix inches apart, to remain a year or two, then tranſplanted into the flower-borders, where they will flower the ſucceeding ſummer, and will endure many years, increaſe exceedingly in magnitude, and flower every year ſtronger.

All the neceſſary culture is, to cut down the decayed ſtalks every autumn, dig the ground in winter or ſpring, and keep them clean from weeds in ſummer.

DIGGING.—Digging ground may be conſidered as a ſort of garden-tillage, or neceſſary preparation of the ſoil for the reception of all ſorts of ſeeds and plants, and which ſhould be duly performed annually, either in autumn, winter, or ſpring, particularly for every new crop, and is alſo beneficial to crops of perennial ſtanding, whether eſculent flowers or ſhrubs, &c.

This operation is performed two different ways.—Plain digging,—and digging by trenches, commonly called trenching.

Plain Digging.—This is beginning at one end of any piece of ground, bed, or border, and dig it one ſpade deep, right back ſpit and ſpit regularly to the place where you finiſh; the method is this, begin as aforeſaid at one end of the piece of ground you intend to dig, and with your ſpade open a trench quite a-croſs, one good ſpade wide, and one deep, carrying the earth to the end or place where you finiſh; then keeping your face to the opening, proceed to digging one ſpade deep regularly from one ſide of the piece to the other, turning the ſpits neatly into the trench, and the next courſe againſt theſe, and ſo keep digging ſtraight back, ſpit and ſpit, ſtill preſerving an open trench, a good ſpade width and depth, between the dug and undug ground, that you may have full room to give every ſpit a clean turn, taking all the ſpits perpendicularly, and not take too much before the ſpade, eſpecially in ſtiff land, or where the ſurface is full of weeds, or is much dunged; ſo giving every ſpit a clean turn, the top plump to the bottom, and the bottom to the top, that the weeds or dung on the ſurface may be buried a due depth, and that the clean freſh earth may be turned up.

As you proceed break all large clods, and preſerve an even ſurface, carrying both ſides and middle on equally, unleſs one ſide ſhall be hollow; then carry on the hollow ſide firſt, in a kind of gradual ſweep, inclining the ſpits of earth rather that way, which will gradually raiſe that ſide, and reduce the high one, obſerving the ſame if both ſides are high and the middle hollow, or both ſides hollow and

the middle high, always keeping the lower ground advancing gradually before the higher, by which you will always maintain a uniform level, whether horizontal or declining.

The ſame ſhould alſo be obſerved in beginning to dig any piece of ground, that if one corner is much lower than the other, carry on the lower part ſomewhat firſt, in a kind of eaſy ſweep or ſlanting direction, as far as neceſſary; likewiſe in finiſhing any piece of digging, that if one corner ſhall be low and the other high, carry the digging gradually round upon the lower ſide, ſo as to finiſh at the higheſt corner; and having digged to the end, or that part of any piece of ground where you intend to finiſh, then uſe the earth digged out of the firſt trench to make good the laſt opening equal with the other ground.

In plain digging dunged ground, if the dung is quite rotten, you may either dig clean through, giving each ſpit a clean turn, to bury the dung plump in the bottom of the trench; but if you cannot readily do this, trim the dung a ſpade's width at a time into the furrow or open trench, and ſo dig the ground upon it, which is rather the moſt effectual method, whether rotten or long freſh dung.

In the courſe of digging, all root-weeds that are perennial ſhould be carefully picked out, particularly couch-graſs and bear-bind, the *Convolvulus Sepius*, for the leaſt bit of either will grow, encreaſe greatly in ſummer, and prove moſt troubleſome weeds.

But ſlight rooting weeds on the ſurface being turned clean to the bottom, will rot, and never trouble you again.

Digging by trenches, or trenching.—This is called trenching, becauſe the ground is digged in regular trenches, trench and trench, of two or three ſpades width, and one, two or more deep in the following manner:

Begin at one end of the piece of ground, and open a trench by line and ſpade two full ſpades width at leaſt, and one or two deep, and wheel the earth to the place where you ſhall finiſh, then mark out a ſecond trench of the ſame width, pare all weeds on the ſurface into the bottom of the firſt, and then beginning at one end of the ſecond, and ſtanding ſide-ways to the other, dig it the full width and depth as above, turning the earth into the firſt trench, obſerving, that if you go two ſpades deep, dig the top ſpit along firſt, then beginning again at the end, dig the ſecond courſe; then mark out a third trench, dig it into the ſecond, and ſo proceed trench and trench to the end of the ground, remarking, that if you would have each courſe of ſpits in the ſeveral trenches their full depth, it is proper to ſhovel up the crumbs or looſe earth at bottom of each courſe; ſo may dig either one ſpade deep and the crumbs, or two and crumbs as ſhall ſeem neceſſary, but by no means go below the good ſoil; and one good full ſpade deep, with a good paring at top, is, for common trenching ſufficient for general crops of moſt ſorts of plants, and more than that is only neceſſary on particular occaſions, and for particular plants, which will always be hinted in the reſpective articles.

I would however obſerve, that by trenching occaſionally two ſpades deep where the ſoil admits, by turning the bottom ſpit to the top, renews the ſoil; and by turning the exhauſted or worn-out earth to the bottom that depth for two or three years, gives it a ſort of reſpite to recruit new vigour in its vegetative quality, that being again trenched up to the top will produce crops the more abundantly, and in greater perfection.

It is indeed good culture when practicable, to trench two moderate ſpades deep, with or without the crumbs, for carrots and parſnips and ſuch like roots which ſtrike deep into the ground, and for liquorice three full ſpades deep is neceſſary, for the roots, the uſeful part, often ſtrike down four feet deep.

The merit of trenching in general, is ſuperior to plain digging for principal crops, or any plantations, in that the top ſoil, all weeds and dung are more effectually buried in the bottom, and the freſh ſoil at bottom more readily turned to the top, which is of conſiderable importance in the growth of all ſeeds and plants; therefore in digging ground for any general crops or plantations of young trees, &c. I ſhould adviſe to dig it principally by trenches one good ſpade deep at leaſt, or two occaſionally, eſpecially when neceſſary to renew the ſoil, or as you ſhall judge proper for long-rooted eſculents, as carrots, &c. or plantations of choice fruit trees.

In all trenching, whether one, two, or more ſpades deep, always, previous to digging, pare the top of each trench two or three inches deep or more, with all weeds and other litter into the bottom of the open one, which not only makes clean digging, and encreaſes the depth of looſe ſoil, but all weeds, as alſo the ſeeds of them that may have ſcattered on the ſurface are regularly buried at ſuch a depth,

depth, that the weeds themſelves will rot, and their ſeeds cannot vegetate.

In trenching dunged ground, if you trench but one ſpade deep bury the dung of each trench regularly in the bottom; but if two ſpades deep, it will be eligible to bury the dung between the two ſpits, that is, triming back the dung, dig the firſt courſe, turning it into the bottom of the open trench, then trim in the dung upon that, and dig the ſecond courſe and turn it in upon the dung, and ſo proceed trench by trench.

When intending to trench for ſpring crops, or even for any autumn or winter plantation, it is good culture to perform it ſome conſiderable time before, to lie fallow till the time for ſowing or planting, to meliorate by the weather; but more particularly for ſpring crops, ſo that if it is trenched up in rough ridges in winter, to lie till ſpring, and then levelled down, proves very beneficial to plants of all ſorts.

I would alſo adviſe, that all trenching in winter, intended for ſpring crops, be trenched up in rough ridges, that is, inſtead of forming a level ſurface, lay the earth of each trench in a ſharp ridge, as you advance with the work, laying the ſpits of earth rough, that the ſoil may lie hollow to receive the greater benefit from the ſun, air, and froſt, to meliorate and enrich its quality.

The above method of ridging the trenches, is univerſally practiſed by the London kitchen-gardeners, even if the trenching is done in ſpring, and is to lie but a week, or two or three days, for it is ſoon levelled down when to be ſown or planted, and it greatly improves the ground.

The ridges are ſoon levelled down in ſpring, or when the ground is wanted for ſowing or planting, obſerving to chuſe dry weather for this work, levelling them regularly ridge and ridge lengthways, ſtirring all the ground, and preſerve an even ſurface; and if the ground is for ſowing with ſmall ſeeds, do not level down much more than you can ſow the ſame day, for fear of rain coming to render the ſurface cloggy, or the ſun and winds dry it too much, as moſt land is always in beſt order for ſowing while it is freſh ſtirred, for it not only falls to pieces more readily in raking, to cover the ſeed more effectually, but freſh ſtirred land promotes a quick and free germination in the ſeed.

Gardeners that have large grounds often hire the digging by the rod, the prices generally according to the nature of the ground, whether light, looſe, clean, and eaſy to be digged, or of a ſtiff nature, and whether it is clean or foul with weeds, or not dunged, or dunged, and whether by plain digging, or digging by trenches.

The prices by plain digging, that for light clean free-working ground, is, about London, commonly two-pence, or two-pence halfpenny per rod; and if dunged, three pence. But ſtiff ſtubborn-working land is often three-pence or four pence without dung; and where ground is very full of perennial weeds, ſuch as couch graſs, bear-bind, and the like, which ſhould all be picked out by hand, an extra allowance is generally given per rod, a half-penny or penny, according as the ground is leſs or more foul.

The prices by trenching is, that for one ſpade deep, and a top paring, commonly from two pence halfpenny to four pence, according to the nature of the ground, and whether dunged, or clean, or foul with weeds, though clean free-working ground is generally digged with dung one ſpade deep for three pence, and if two ſpades deep, from four pence to ſix pence, or eight pence.

A man will dig by plain digging, of light, free-working clean ground, eight, ten, or twelve rod a day, from ſix to ſix, though in ſome of the light clean ground about London, I have known a man turn up fifteen or twenty rod a day, from five to ſeven; on the other hand, in ſtiff ſtubborn ſoils a man may work hard for ſix or eight rod in a day of twelve hours. And that digging by trenches, or trenching, if only one ſpade deep, without the crumbs, or ſhovelling at bottom, a man will dig almoſt as much as by plain digging; and by double digging, or two ſpades depth, from four to ſix rod a day may be good work, though in harſh-working ground, a man may labour hard to get up three or four rod a day.

DIGITALIS, Fox Glove.

This genus furniſhes hardy, herbaceous, tall, flowery, biennials and perennials for the pleaſure-ground, and a tender ſhrubby exotic for the green-houſe, all of them adorned with long, ſpear-ſhaped, ſimple leaves, and long ſpikes of large bell-ſhaped flowers.

Claſs and order, *Didynamia Angioſpermia.*

*Characters.*] CALIX is five-parted and perſiſtent. COROLLA is monopetalous, bell-ſhaped, tubular, and with the limb ſlightly four-parted, having the upper lip ſpreading and emarginated, and the under one largeſt. STAMINA, two long and two ſhort filaments inſerted

inſerted into the baſe of the Corolla, and bipartite antheræ. PISTILLUM, an acuminated germen, ſimple ſtyle, and acute ſtigma. PERICARPIUM, an oval, bivalvular, bilocular capſule, and angular ſeeds.

There are about four herbaceous and one ſhrubby ſpecies, retained in our gardens as plants of ornament.

The firſt four are herbaceous and hardy.

[1]DIGITALIS *Purpurea.*

*Purple Common Fox Glove.*] Digitalis, with an upright ſtrong ſtalk three or four feet high, garniſhed with long, rough, hairy leaves, and terminated by a long looſe ſpike of large purple flowers ranged along one ſide, having oval leaves to the calix, and obtuſe corolla, with an entire upper lip.

*Variety*] With white flowers.

[2]DIGITALIS *Lutea.*

*Yellow Fox Glove.*] Digitalis, with an upright ſtrong ſtalk two or three feet high, garniſhed with long, ſpear-ſhaped, ſmooth leaves, and the upper part with a long ſpike of yellow flowers ranged along one ſide, having the leaves of the calix ſpear-ſhaped, an acute corolla, and bifid upper lip.

*Varieties are*] With ſmall yellow flowers—with large yellow flowers——with narrow leaves and ſmall yellow flowers.

[3]DIGITALIS *Ferruginea.*

*Ferruginous, or Iron-coloured Fox Glove.*] Digitalis, with an upright ſtalk five or ſix feet high, adorned with narrow leaves three inches long, and terminated by a very long erect ſpike of iron-coloured flowers, having oval leaves to the calix, and the lower lip of the corolla very long.

[4]DIGITALIS *Thapſi.*

*Thapſi, or Purple Spaniſh Fox Glove.*] Digitalis, with an upright ſtalk a foot and a half high, garniſhed with very long, woolly, rough, veined, decurrent leaves, and terminated by a ſhort ſpike of purple flowers.

Shrubby and tender.

[5]DIGITALIS *Canarienſis.*

*Canary Shrubby Fox Glove.*] Digitalis, with a ſhrubby, upright, branchy ſtalk riſing five or ſix feet high, ſpear-ſhaped, rough leaves four or five inches long, and half as broad, and with all the branches terminated by looſe ſpikes of flowers, having the calycinal leaves ſpear-ſhaped, and an acute two-lipped corolla.

The flowers of all theſe ſpecies of Digitalis are of one bell-ſhaped petal, moderately large, and moſtly ranged along one ſide of the ſtalk. See the *Characters.*

Of theſe ſpecies the firſt ſort grows wild in moſt parts of Britain, but all the others are of foreign growth. All the herbaceous kinds are hardy, and proſper any where, but the ſhrubby ſort requires ſhelter of a green houſe in winter.

The four herbaceous ſpecies are biennial and perennial, all of them riſe firſt with a large tuft of leaves, crowning the root, and amidſt them riſe the ſtalks in ſpring, flower in June, ripen ſeeds in autumn, and the ſtalks and leaves ſoon after decay, and ſometimes alſo the root, eſpecially of the firſt ſort, which is ſeldom more than biennial.

All the herbaceous ſpecies may be employed as plants of ornament in the embelliſhing the different compartments of the pleaſure-ground, and will proſper in any common ſoil and expoſure.

The ſhrubby ſort claims a place among the green-houſe exotics, is a very pretty flowering plant, often continuing its bloom from May till October.

*Propagation, &c.*

The herbaceous ſorts are raiſed from ſeed in the common ground, ſown in autumn or ſpring, but which if ſown in autumn are commonly more ſucceſsful; when the plants are come up three inches high, prick them out at ſix inches diſtance, to remain till autumn, then tranſplant them where they are to flower.

The ſhrubby ſort is alſo raiſed from ſeed, ſowed in pots of rich earth in autumn, &c. and placed in a garden-frame to have occaſional protection from froſt, exceſſive rains, and cold; and when the plants are two or three inches high, plant them ſeparate in ſmall pots, and afford them ſhelter during cold weather, and place them in the green-houſe in winter.

DIOSMA, African Spiræa.

This genera compriſes ſeveral low ſhrubby exotics for the green-houſe, garniſhed with ſmall entire leaves, and numerous, ſmall, quinquepetalous flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is five-parted, plane at the baſe, and perſiſtent. COROLLA, five oval, obtuſe, erect petals, and a coronated quinquefid nectarium. STAMINA, five filaments, and oval, erect antheræ. PISTILLUM, a germen crowned by the nectarium, ſimple

ſimple ſtyle, and obſolete ſtigma. PERICARPIUM, five united capſules, each having one oblong, depreſſed, ſmooth ſeed.

The ſpecies are,

[1]DIOSMA *Oppoſitifolia.*

*Oppoſite-leafed Dioſma* ] Dioſma, with a ſhrubby ſtem, branching irregularly three or four feet high, garniſhed with awl-ſhaped, acute leaves, placed oppoſite, and numerous, ſmall, white flowers all along the ſides of the branches.

[2]DIOSMA *Hirſuta.*

*Hairy Sweet-ſcented Dioſma.*] Dioſma, with a ſhrubby ſtem, branching regularly five or ſix feet high, narrow hairy leaves, placed alternate, and cluſters of white flowers at the ends of the branches.

[3]DIOSMA *Rubra.*

*Red Flowering Dioſma* ] Dioſma, with a ſhrubby ſtem branching three feet high, narrow, acute, ſmooth leaves, keel-ſhaped underneath, and ſpotted on both ſides, and red flowers.

[4]DIOSMA *Ericoides.*

*Heath-leafed Dioſma.*] Dioſma, with a ſhrubby ſtem branching three or four feet high, narrow ſpear-ſhaped leaves, convex underneath, and imbricated two ways.

All theſe plants are natives of Africa, and require the ſhelter of a green-houſe here in winter. They are all very ornamental during their bloom, and moſt of them impart a fragrant odour, ſo are worthy of a place in every curious green-houſe collection.

*Propagation, &c.*

All the ſorts are propagated plentifully by cuttings in ſpring or ſummer, planting them in pots, ſeveral in each, and plunge them in a hot-bed, they will be well rooted in two months, and may then be potted ſeparately, and managed afterwards as other green-houſe ſhrubs. See GREEN-HOUSE PLANTS.

DODECATHEON, American Bear's-ear, formerly *Meadia.*

It furniſhes one low, flowery perennial for the pleaſure ground, adorned with umbellate cluſters of monopetalous flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX, a many-leafed involucrum, and each floret having a monophyllous, five-parted, permanent cup. COROLLA, many florets, forming a ſort of umbel, each floret monopetalous, cut into five retroflexed ſegments. STAMINA, five ſhort filaments, and arrow-pointed antheræ, connected into a beak. PISTILLUM, a conical germen, ſlender ſtyle, and obtuſe ſtigma. PERICARPIUM, an oblong, oval, unilocular capſule, containing many ſmall ſeeds.

The ſpecies is,

DODECATHEON *Meadia.*

*Virginian Dodecatheon, formerly called Meadia.*] Dodecatheon, with a yellow perennial root, crowned by ſeveral long ſmooth leaves, ſix inches long and two or three broad, and between them erect flower-ſtalks eight or ten inches high, each terminated by an umbellate cluſter of quinquefid, retroflexed, purple flowers. See the *Characters.*

This is a hardy perennial, flowers very ornamentally in May, ripens ſeeds in July, and the ſtalks and leaves decay in autumn, ſo are renewed from the root annually in ſpring.

It will ſucceed in any of the common borders, but is the moſt proſperous in a ſomewhat ſhady ſituation.

*Propagation.*

Its propagation is by ſeed, and by off-ſets of the roots.

By Seed.—Sow the ſeed in autumn, ſoon after they are ripe, in a ſhady border, or in pots, moving them to occaſional ſhade in hot weather, the plants will come up in the ſpring, and when their leaves decay, plant them on a ſhady border, ſix or eight inches apart, to ſtand a year; then tranſplant them into ſhady flower-borders.

By Off-ſetts.—In Auguſt or September, when the leaves decay, is the propereſt time to remove the roots, and take off the ſlips for encreaſe, planting them again directly, and each off-ſet will flower the following ſummer.

DORONICUM, Leopard's-Bane.

The plants are hardy, herbaceous perennials, for the large departments of the pleaſure-ground, they obtaining from eighteen inches to three feet ſtature, terminated by large compound flowers.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX compound radiated flower, having the general cup formed of a double ſeries of long narrow leaves. COROLLA, many tubular hermaphrodite florets form the diſc, and ligulated females the radius. STAMINA, five filaments and cylindric antheræ. PISTILLUM, a germen, ſmall ſtyle, and in the hermaphrodites an indented ſtigma, in the females two, which are reflexed. PERICARPIUM, none. SEMEN, a ſingle furrowed downy ſeed under each floret.

The material ſpecies are,

[1]DORONICUM *Pardalianches.*

*Greateſt Leopard's-Bane.*] Doronicum, with thick, fleſhy, knotty, penetrating roots, crowned by a cluſter of heart-ſhaped hairy leaves on long foot-ſtalks, and amidſt them upright channelled ſtalks, three feet high, garniſhed with a few amplexicaule leaves, and each terminated by one large compound radiated yellow flower.

[3]DORONICUM *Plantagineum.*

*Plantain-leafed Leopard's-bane.*] Doronicum with thick fleſhy roots crowned by oval acute-pointed leaves; and between them upright ſtalks two feet high, and alternate branches, ſurmounted by large compound yellow flowers.

[2]DORONICUM *Bellidiaſtrum.*

*Bellidiaſtrum, or Wild Daiſy leaved Leopard's Bane.*] Doronicum with ſhort hairy leaves, and upright ſimple naked ſtalks a foot high, terminated by one white and yellow flower.

*Variety.*—With broad leaves, taller ſtalks, and red and white flowers.

All theſe plants are hardy and perennial in root, but annual in ſtalk, which riſe in ſpring, flower in May, ripen ſeeds in July, and decay to the root in autumn.

The flowers are univerſally compound and radiated. See the *Characters.*

Theſe plants may be employed in the large departments of the pleaſure ground, where many plants of eaſy culture are required to encreaſe the variety; for they will grow any where, and where the ſeeds ſcatter many young plants will riſe naturally.

*Propagation.*

They are eaſily propagated by ſeed, and by their ſpreading roots; either of which may be performed in autumn or ſpring.

Sow the ſeed on the ſurface, and rake it in, and when the plants are two or three inches high prick them in beds nine inches diſtance, which tranſplant in autumn where they are to remain.

Off-ſets of the roots taken off in autumn, or early in ſpring, will flower in May following.

## DRACOCEPHALUM, Dragon's-head.

It conſiſts of herbaceous perennials and annuals for the pleaſure-ground and greenhouſe, riſing with upright ſtalks, from about eighteen inches to three feet high, garniſhed moſtly with entire leaves, and whorled ſpikes of ſmall monopetalous ringent flowers.

Claſs and order, *Didynamia Gymnoſpermia.*

*Characters.*] CALIX is monophyllous, tubular, and permanent. COROLLA is monopetalous and ringent, with large inflated chaps, having an obtuſe arched upper lip, and the lower one trifid. STAMINA, two long and two ſhort filaments, and heart-ſhaped antheræ. PISTILLUM, a four parted germen, ſlender ſtyle, and bifid reflexed ſtigma. PERICARPIUM, none. SEMEN, four naked ſeeds lodged in the Calix.

The principal ſpecies are,

[1]DRACOCEPHALUM *Virginianum.*

*Virginian Perennial Dracocephalum.*] Dracocephalum with upright, four-cornered ſtalks a yard high, adorned with ſpear-ſhaped ſawed leaves, oppoſite at each joint; and terminated by erect ſpikes of purple flowers in July and Auguſt.

[2]DRACOCEPHALUM, *Ruyſchiana.*

*Ruyſchiana, or blue-ſpiked perennial Dragon's-head.*] Dracocephalum with an upright ſquare ſtalk two feet high, garniſhed with very narrow ſmooth entire leaves; and terminated by whorled ſpikes of large blue flowers, having ſmall bractæ under each whorl; it flowers in June, and the ſeeds ripen in autumn.

[3]DRACOCEPHALUM, *Moldavica.*

*Moldavian annual Dracocephalum*, or *Moldavian Balm.*] Dracocephalum with upright branchy ſtalks a foot and half high, garniſhed with oblong deeply-ſawed leaves, and terminated by whorled ſpikes of blue flowers; and the whole plant emits a very balſamic fragrance:

*Variety.*—With white flowers.

Both the varieties flower in July, and the ſeed ripens in September.

DRACOCEPHALUM, *Canarienſe.*

*Canary ſweet-ſcented perennial Dracocephalum, commonly called Balm of Gilead.*] Dracocephalum with upright ſquare perennial ſtalks three or four feet high, garniſhed with compound leaves of three or five ſawed lobes, and ſhort ſpikes of pale blue flowers, appearing moſt part of ſummer, and the whole plant emits a ſtrong balſamic odour.

The firſt three ſpecies are hardy, the firſt two of which are perennial, but the third is annual, all of them may be employed as plants of ornament, of which the firſt and ſecond have the moſt merit as flowering plants, though they may be all employed to good advantage in forming variety in extenſive grounds, and will proſper in any common ſoil.

The

The fifth ſort, *Balm of Gilead* is ſomewhat tender, requiring ſhelter of a green-houſe or garden-frame in winter, by which care it will retains its ſtalk and leaves the year round, ſo may be conſidered as an herbaceous-ſhrubby evergreen; it will however ſometimes live in the full ground in a warm dry border, in mild winters, but this is not always to be depended on, therefore ſhould keep them principally in pots, to move to occaſional ſhelter in winter, but they only want protection from froſt; great quantities of this plant are cultivated by the ſetting gardeners about London for the markets, where they are ready ſale, at ſix pence or nine pence per pot.

*Propagation.*

The firſt ſort may be raiſed from ſeed, and by parting the roots, but it propagates plentifully by the latter method, which may be performed in autumn, or early in ſpring.

The ſecond ſort is raiſed plentifully from ſeed ſown in a bed of light earth in April, and when the plants are two or three inches high, prick them out at ſix inches diſtance, giving occaſional water, and ſhade from the ſun till rooted, ſo to remain here till October; then tranſplant them with balls into the borders, and other compartments of the pleaſure-ground, obſerving, that it is proper to raiſe ſome freſh plants every two years, to ſucceed the old ones.

The third ſort and variety, being annual, are raiſed every year from ſeed, ſown in ſpring in ſmall patches in different parts of the borders where the plants are to remain to flower. See HARDY ANNUALS.

The fourth ſort is propagated eaſily by ſeed and by cuttings.

By Seed.—It may be ſowed in autumn or ſpring, the autumn ſowing will ſometimes riſe the ſame ſeaſon, or if not, they will ariſe early in ſpring, and be forwarder than the ſpring ſowings; they ſhould be ſown in pots of light rich earth a quarter of an inch deep, and ſheltered in a frame, or glaſs caſe, occaſionally in cold weather; and when the plants are two inches high, tranſplant them into ſeparate ſmall pots

By Cuttings.—Cuttings of the ſtalks and branches about five or ſix inches long, planted any time in ſummer, either in a ſhady border, or plant ſeveral in large pots, moving them to occaſional ſhade, and give waterings in dry weather, they will readily take root, and towards autumn may be planted in ſeparate pots.

DRILL-SOWING, &c. In gardening, drills are ſtraight narrow openings, formed in the earth with a hoe, from half an inch to five or ſix deep, for the reception of the ſeeds and roots of certain plants, which ſucceed beſt by that mode of culture.

Many ſorts of eſculents ſucceed by this method, as for example, all ſorts of peas, and kidney-beans ſhould always be cultivated in drills, for as the ſeed being rather large, by forming drills an inch or two deep for their reception, they are more conveniently ſowed, and covered regularly at a proper depth with earth; and that the drills being in ſtraight ranges two or three feet aſunder, the plants conſequently riſe in rows that diſtance, whereby there is due room between the rows, to hoe the ground, to deſtroy weeds, and to looſen the ſoil, and draw it up occaſionally on each ſide of the plants to ſtrengthen them, and forward their growth; likewiſe when their produce is ready, their ſtanding diſtant in drills allows room to go in between, to gather the crops without damaging the plants: broad-beans are alſo ſometimes drilled in, though they are more commonly planted with a dibble; however, in drills two or three inches deep they may be planted to great exactneſs, and covered all an equal depth, allowing the drills three feet diſtance at leaſt: aſparagus plants are alſo planted more commodiouſly in drills ſix inches deep, than by any other method. Parſley, coriander, chervil, and all ſmall ſallad-herbs, ſuch as creſſes, muſtard, &c. ſhould alſo be ſown principally in drills half an inch deep, as in which, the herbs are more eaſily cleaned, and more readily gathered for uſe. Spinach is alſo ſometimes ſowed in ſhallow drills, but more eſpecially when cultivated between rows of other plants, as that of broad-beans, early cabbages, &c. it however ſhould be ſowed thin, otherwiſe the plants will draw each other weak; but I would rather adviſe the main crops of this plant to be ſowed principally broad-caſt over the ſurface of the ground, and raked in, and the plants hoed out to four or five inches diſtance. Beet having large ſeed, may be ſown in inch-deep drills, in order, that they may be more effectually buried an equal depth. See the reſpective articles.

Many ſorts of the larger ſeeds, nuts, &c. of trees, ſhrubs, and herbaceous plants, may alſo be ſowed in drills an inch or two deep, in proportion to their ſeveral ſizes.

Bulbous, and tuberous flower-roots are al-

ſo planted with great facility and exactneſs in drills of due width and depth; but theſe kind of roots are moſt commonly planted with a dibble; I ſhould however, rather recommend the drilling, eſpecially for ſuch that are to be cultivated in continued rows, or in beds, proportioning the width and depth of the drill to the ſize of the reſpective roots; as for example, if for crocus, ſnow-drop, winter-aconite, anemone, ranunculus and the like, two or three inches wide and deep is ſufficient; but for the larger kind, ſuch as hyacinths, narciſſus, tulips, lilies, &c. from three or four, to five or ſix inches depth is neceſſary, and from ſix to twelve inches between the rows; placing the roots bottom downward plump in the bottom of the drills at the ſame diſtance, and draw the earth evenly over them; but for more particulars, ſee the reſpective articles.

With reſpect to the method of drawing or forming drills, this ſhould generally be performed by hoe and line; that is, ſet a line as tight as poſſible, then with a common hoe held corner-ways, with the edge cloſe to the line, draw the drill along accordingly, from half an inch to five or ſix deep, as the different ſorts of ſeeds and roots ſhall require, as exhibited in the reſpective articles.

Though drills for ſome particular ſmall ſeeds, may be drawn with the hoe flat-ways, i. e. the edge downward, ſo as to make a broad flat-bottomed drill, half an inch, or an inch deep; which, for inſtance, may be more particularly neceſſary for the different ſorts of ſmall-ſallad herbs, ſpinach, &c. when intended to raiſe them in drills, and for many kinds of flower ſeeds ſown for tranſplantation.

But for ſeeds of tender plants, which may require the aid of hot-beds, and if neceſſary to ſow them in drills, as a hoe cannot be introduced, the ends of the two firſt fingers, or that of a ſhort flat ſtick, an inch or two broad, will form a proper drill.

As ſoon as the ſeeds or roots of any ſort are ſowed or planted in drills, draw the earth over them evenly, either with a hoe or rake, or with the hand for the very ſmall or more delicate ſorts; though for the large kinds, ſuch as peas, kidney beans, broad-beans, &c. may turn the earth in upon them expeditiouſly with the feet alternately, being careful to cover all an equal depth, and trim the top of each drill clear from ſtones and clods, ſo as to leave a ſmooth ſurface.

DUNGS. In gardening there are two admirable properties in Dungs, viz.

The one is to repair the decays of worn-out or exhauſted ſoils, and to meliorate and fatten the earth and render it fertile: the other is to produce a certain degree of heat when formed into hot-beds; which, in ſome meaſure ſupplies the office performed by the heat of the ſummer's ſun, by producing crops of choice plants, fruits, and flowers in winter, or early in ſpring, that could not be obtained in the natural ground before ſummer; the former of which properties, (as manure) is effected both by new and old or rotten Dungs; and that of various ſorts, but the latter property (for hot beds) is only to be found in one particular ſort, i. e. horſe-dung, including the wet litter and Dung together, as it comes from the ſtables, and while it is newly made, before it rots and loſes its heat.

Dungs for Manure.—Various ſorts are recommended and uſed, according to the qualities of the ſoil they are deſigned to reſtore, meliorate, and enrich.

As for example; ſome lands are very moiſt, heavy, ſtubborn, and cold; to improve which, ſome Dungs are of a hot light quality, as that of horſes, ſheep, and pigeons, &c. tho' for gardens, horſe or ſtable Dung, tolerably rotted, either alone, or mixed with light materials, is the beſt of all to uſe in any conſiderable quantity for ſuch land: on the other hand, ſome ground is light, dry, and hot, and requires moiſt, fat, and cooling Dungs, as that of oxen, cows, hogs, &c. to render the ſoil fatter, and more compact to retain its virtue. However, a mixture of all theſe, i. e. horſe, and neat or cow Dung, &c. tolerably rotted, will ſuit almoſt every ſort of ſoil, or either of them alone, eſpecially if thoroughly rotten, will prove beneficial to moſt kinds of garden land.

Horſe-dung, however, is certainly the beſt improvement for cold land that can be procured, and may be uſed ſucceſsfully both new and rotten; not however uſed new or ſtrawey for carrots, parſnips, or other eſculent roots of ſimilar growth, but for any other above-ground crops; new horſe-dung juſt as it comes from the ſtable, may be uſed to much advantage in cold moiſt land, which in ſuch ſoils frequently ſucceeds better than that which is quite rotten, as that of old hot-beds, or of the like nature.

We may alſo conſider horſe-dung the moſt uſeful of any for gardens, and is the moſt common Dung uſed as manure in many places, eſpecially after having rotted in dunghills, or having

having been previouſly uſed for hot-beds in winter and ſpring, for early and tender crops; which crops being all gone by autumn, or winter following, when the Dung of the hot-bed will have become rotten and buttery, and is then carried off as manure, into the different departments of the garden, &c. and when thus rotted, is beneficial for all ſorts of ſoils, and is very enriching.

And as to cow or oxen Dung, although it is particularly beneficial in light looſe ſoils, yet, when well rotted it will alſo prove good manure for any; and with this and horſe or ſtable-dung, as alſo hogſtye-dung together, mixed, makes an excellent manure for moſt ſorts of land.

Hogs Dung being very fat, is by ſome recommended as the moſt beneficial of all ſorts of Dungs, and, when well rotteed, has often proved excellent for fruit trees, in a light ſoil, eſpecially for apples and pears, but when thoroughly rotted, may be uſed to advantage for all ſorts, in light dry land.

Sheep and deer Dung have been found great improvers of cold clayey land.

The Dung of pigeons and other poultry being hot and full of ſalts, is found good for cold wet clayey lands, but before uſing, it would be an advantage, if expoſed abroad in the dung-hill ſome conſiderable time to rot, ſweeten, and to mollify the fiery heat natural to thoſe Dungs; and if then mixed with light earth, ſand, or aſhes, to keep it from clinging, and then, after having lain ſix, eight, or twelve months, ſtrew it over the ground in autumn or winter in moderate quantities, being dug in lightly, it will tend much to facilitate vegetation in cold heavy ſoils.

Human ordure, mixed with other Dungs, and earths, by way of compoſt, and expoſed to the air ſome time, will prove beneficial to cold, ſour, ſtubborn land.

For other ſorts of Dungs, &c. uſed as manure, ſee MANURE.

All Dungs uſed as manure, ſhould be applied principally, either in autumn, winter, or ſpring; and if it is horſe or neats Dung or a mixture of both, or of hog's Dung, or the like, it ſhould be laid at leaſt from about three to ſix inches thick all over the ſurface; but on poor land, if double that thickneſs it will prove the more beneficial to the ground; but the hot fiery Dung of poultry ſhould be uſed more ſparingly, and that, only to cold, heavy land.

In digging or trenching dunged ground, the Dung ſhould be buried one ſpade, not more, ſo that if you trench two ſpades deep, always bury the Dung betwixt the firſt and ſecond ſpit.

Dungs for hot beds.—Horſe-dung, together with the wet litter of their ſtalls, is the only ſort capable of producing the effect of heat requiſite for hot-beds, but which property is found only in that which is newly made, or at leaſt that have not laid ſo long on the dung-hill as to begin to rot conſiderably, and has quite expended its heat. Preparatory to forming this Dung into hot-beds, the neceſſary quantity ſhould be caſt up in a heap, ſhaking and mixing the long and ſhort well together, and here it ſhould remain a week, twelve days, or a fortnight, to prepare all the parts to an equal quality, obſerving, if the Dung is new and ſtrawey, it will require to lie longer than older or ſhort Dung; and if the heap is turned over once or twice, the rank, unwholeſome ſteam and burning quality, will evaporate more effectually. See HOT-BEDS, &c. &c.

DWARF TREES, theſe are fruit trees graſted near the root, that they may form heads, not more than from about four to ſix or eight feet high.

Under this head may be conſidered not only Drawf-ſtandards, but alſo all ſorts of Dwarfs for eſpaliers, and walls, which are alſo graſted or budded low, to provide branches near the ground, ſo as to cover every part of the eſpalier or wall, from the bottom upward, moſt of which ſort of Dwarf-trees are graſted or budded upon Dwarf ſtocks, or ſuch as are but moderate ſhooters, particularly for Dwarf-ſtandards, to preſerve them as dwarfiſh as poſſible. See STOCKS. And in which, the graft or buds are inſerted, within about ſix, eight, or twelve inches of the bottom, and the firſt ſhoots from the graft or bud, are in ſpring, when a year old, headed down to five or ſix eyes, to force out lower ſhoots to form the firſt ſet of branches near the root, as a foundation for the upper part, and by ſhortening theſe alſo, as above, if neceſſary, a farther ſupply is produced, to give the tree its firſt regular form, whether as a Dwarf-ſtandard, or for eſpaliers, or walls. But as in this article we ſhall only treat of Dwarf-ſtandards, ſo for the other ſorts of Dwarfs, ſee ESPALIERS and WALL TTEES.

Dwarf ſtandards therefore, are formed at firſt as above, not trained fan-faſhion like eſpaliers,

eſpaliers, or wall trees, but promoted to branch out low every way into a circular head, without being trained to any kind of fence, and are therefore properly ſtandards, though of dwarfiſh ſtature.

Theſe were formerly in great eſtimation, and trained in three different ways or ſhapes, viz. 1. Concave Dwarfs; being trained concave or hollow in the middle, having all the branches ranged circularly around the ſtem in an aſcending direction, ſo as to form the heart of the tree hollow or concave. 2. Convex or conical Dwarfs, being trained convex or full in the middle, ſo as to form a cloſe conical head. 3. Horizontal Dwarfs, being trained horizontally, i. e. all the branches trained flat, or in a horizontal poſition, all around parallel to the ſurface of the earth; but the concave form is the moſt eligible; but neither of the methods are at preſent in much practice, and the mode of training Dwarfs in eſpaliers, is now almoſt univerſally adopted in their ſtead; which indeed, are every way preferable, both for convenience and bearing; however, a few trees ſhould be admitted in large grounds for variety, and may be diſpoſed ſingly, one here and there, upon large borders, or on open ſpaces of graſs ground.

They ſhould be no where planted nearer together than twenty feet, particularly the concave and horizontal Dwarfs.

The ſorts of fruit trees commonly uſed for Dwarf-ſtandards, are apples, pears, plums, cherries, and ſometimes apricots; but any ſort of fruit-trees may be trained in that form, as one direction ſerves for all.

The method of forming them is, and firſt of the concave Dwarfs.

To have proper concave Dwarfs, it is neceſſary to graft them upon Dwarf ſtocks, as before obſerved, that they may be moderate ſhooters, and be of as dwarfiſh ſtature as poſſible; as for example, apples ſhould be graſted upon paradiſe ſtocks, and pears upon quince ſtocks, &c. See STOCKS. And the graft or bud, to be inſerted within ſix or eight inches of the ground; ſo as the ſtem may not exceed a foot or fifteen inches in height, and may form branches within that diſtance of the ſurface of the earth.

Having therefore grafted or budded them as above, obſerve, that the firſt ſhoots from the graft or bud, are to be ſtopped or ſhortened in ſpring, when a year old, to about five or ſix inches in length; or to ſo many eyes or buds, from which to procure from four at leaſt, to ſix or eight ſtout lateral ſhoots, to give the tree its firſt regular formation. When theſe laterals are a year old, and about two feet long, they ſhould be then trained in a horizontal poſition in different directions on each ſide of the ſtem, by means of ſtakes; at the ſame time top the end of each ſhoot, and trim off the lower buds or eyes, to promote a farther ſupply of three, or more ſhoots only towards the ends of each of them; and this ſupply of ſhoots thus again procured, are, after having one ſummer's growth, to be trained gradually in an aſcending direction, at equal diſtances all around, ſo as to form the heart of the tree into a regular concave or hollow; to aſſiſt which, and effect a more regular concavity, ſome wide hoops muſt be placed within-inſide, ſupported by ſtakes; and as the branches advance in length, train them up to the hoops, ſuffering no branch to croſs its neighbour, but train them all parallel to each other, ſix or eight inches diſtance, in an aſcending poſition as aforeſaid; obſerving, if a farther ſupply of ſhoots are ſtill neceſſary to form the tree all around, at the above diſtance, then, ſhortening the laſt produced ſhoots muſt again be practiſed, either wholly or in part, as ſhall appear expedient, to force out, in the proper places, the quantity wanted; afterwards train the whole at full length as directed below in their general pruning, and they will then form all along their ſides, ſhort thick ſhoots ſcarce an inch long, called fruit-ſpurs, as hereafter mentioned.

As to their general pruning, obſerve, in the courſe of that operation, that after the tree is furniſhed with a proper quantity of branches to form the tree into its proper figure all around, as above-noticed, the ſhoots or branches are not afterwards to be ſhortened; obſerving however, that when neceſſary to ſhorten any, either to force out a farther ſupply of young wood to train up for bearers, or to preſerve uniformity, always make the cut on the inſide, ſo as to preſerve the uppermoſt eye, or that immediately next the cut, outward, that the leading ſhoot may advance in that direction, as hereby the concave form of the tree will be better maintained.

However, the ſhortening the ſhoots of theſe trees ſhould be ſparingly practiſed, particularly apples, pears, plums, and cherries, eſpecially after having obtained branches enough to form the tree all around, at ſix or eight inches diſtance, as before obſerved; for ſhortening promotes a great ſuperfluity of

ſtrong

ſtrong ſhoots, and prevents the branches from forming ſpurs or fruit-buds, i. e. ſhort thick ſhoots half an inch, or an inch long; for all theſe ſort of trees above ſpecified, moſtly produce their fruit upon ſpurs, ſee PYRUS and PRUNUS, which generally firſt form themſelves towards the extremity of the ſhoots or branches; ſo that by ſhortening, you cut away the parts where they would have firſt appeared, and inſtead thereof, ſtrong unneceſſary wood will ſhoot forth, and greatly retard the tree in forming for bearing.

Therefore obſerve the caution, never to practiſe ſhortening the branches of theſe kinds of Dwarf trees, but to promote a ſupply of more ſhoots when wanting, as above hinted, or take off cankered parts, or ſuch as are grown much too long, or that grow a-croſs the others; and which ſhould be done in the winter pruning, cutting ſuch parts down to the next moſt ſuitable ſhoot, properly ſituated to ſupply the place of the part cut away.

No branch muſt be ſuffered to grow a-croſs another, but when ſuch appears, let it be cut out, or ſo far retrenched as to preſerve due regularity.

All ſhoots riſing in the middle of the tree, that may interfere with the concavity, ſhould be annually taken off cloſe, either in the ſummer as they are produced, or in the winter pruning. Likewiſe, after the tree is formed and furniſhed with a proper quantity of branches all around at equal diſtances, all ſhoots ariſing from the ſides of the branches ſhould be alſo diſplaced annually, unleſs any ſhall appear neceſſary, to fill any preſent or apparent future vacancy, or to ſupply the place of any irregular, or worn-out branch; in which caſe, leave in the proper places ſome of the moſt promiſing beſt placed young ſhoots, training them up between the old branches; obſerving however, that all ſhoots evidently ſuperfluous, or unneceſſary, ſhould, if poſſible, be diſplaced in ſummer, according as they are produced, which will prove more beneficial both to the form and proſperity of the trees and fruit, than if wholly deferred till the winter; however, do not omit that operation annually, either in ſummer or winter, at either time cutting off all the above-hinted ſuperfluities quite cloſe, and not leave any ſtump, as from every eye of which ſhoots would ariſe and cauſe a great confuſion of wood.

If the tree produce vigorous ſhoots at its extremity, it is neceſſary to leave in ſummer ſome ſtrong lower ſhoots till winter, to check the luxuriance of theſe at top, then take them off according to the above rules.

Be careful at each pruning, to obſerve if there is any appearance of a vacancy, or any very irregular, ill-bearing, or old worn-out branch, or other wood that may want renewing; in which caſe, leave occaſionally ſome well placed young ſhoots towards the lower parts, training them up between the older branches to be coming on gradually to a bearing ſtate, to ſupply the place of bad ones, or any accidental vacancy.

Obſerve alſo at each pruning, to preſerve with the utmoſt care all the fruit-ſpurs, i. e. thoſe ſhort robuſt ſhoots of half an inch, or an inch or two long, for it is from theſe only we are to expect the fruit, which will be evident by obſervation; but if any of theſe are become very long, ragged, or ſtumpy, or crowd others of more eligible growth for bearing, it is proper to thin or regulate them occaſionally as you ſhall ſee neceſſary.

The principal pruning ſeaſons are, the ſummer pruning, which is performed any time in June or July, to clear out all evident ſuperfluous ſhoots of the year; and the winter pruning is any time from November to March, to clear out alſo all ſuperfluous ſhoots omitted in ſummer; and is alſo the only proper ſeaſon to prune out all large branches where neceſſary, either by being ſuperfluous, irregular, bad bearers, or decayed.

Convex or conical Dwarfs. To form theſe, they muſt be grafted or budded low, as directed for the concave Dwarfs, and the firſt ſhoots to be alſo ſhortened in ſpring, when a year old; to procure a further ſupply of ſeveral ſtout lower ſhoots, to form the firſt courſe of branches at about a foot or fifteen inches from the ground; and that, inſtead of forming the heart of the tree concave, like the former kind of dwarf, train the centre-ſhoot up the middle for a ſtem, and ſuffer it to branch out at every twelve or fifteen inches as it advances in height, training each ſet of branches a little horizontally.

Thus the tree may be formed into ſeveral ſets of branches, one above another, which ſhould be ſo ordered, that the lower-moſt ſet be extended the wideſt, and the next ſet immediately above it be a little ſhorter, the next ſhort than that, and ſo on to the uppermoſt ſet, whereby the tree will aſſume a beautiful conic form; and by obſerving nearly the ſame rules of general pruning, as laid down for the

the concave dwarfs, they will produce plenty of fine fruit.

Horizontal Dwarfs.—Theſe are graſted, within from about twelve or eighteen inches, to two feet of the ground, and their firſt ſhoots ſhortened, as for the concave and conical Dwarfs, to promote a regular ſupply of branches at that diſtance from the bottom; which, when about a yard long, are to be trained in a horizontal poſition, ſuffering no upright to advance in the middle, but train the whole perfectly flat or horizontal on every ſide of the ſtem, continuing them as they advance in length always in the ſame poſition, and thus they will ſpread themſelves circularly many feet each way, and produce abundance of fruit.

The ſame mode of pruning is to be here obſerved as directed for the concave Dwarfs, ſo that a repetition here would be ſuperfluous.

---

# E.

EARTH.—Earth may be divided into three claſſes, ſandy, loamy, and clayey.

A good garden Earth may be either of a blackiſh, hazelly; or cheſnut-brown colour neither too light looſe and ſandy, nor partake too much of loam or clay, but is fattiſh, light pliant, and eaſy to work at all ſeaſons; and if three ſpades deep, it will be ſtill more beneficial for the purpoſe, though if there be eighteen inches or two feet depth of good ſtaple, it will do for moſt ſorts of eſculent plants, and others. as well as for almoſt all ſorts of fruit trees.

Sandy Earth.—All the light, looſe, open, and gravelly ſoils, whether black, grey, hazelly, or yellowiſh coloured, till the loam or clay is come at, may be deemed of the ſandy kind, and is capable of raiſing ſome certain plants; but having a mixture of loam or clay, and enriched with dung, it will produce all ſorts; for a vegetable planted either in ſand alone, or in a fat coherent glebe or Earth alone, receives ſcarce any growth, but where there is a juſt mixture of both, the maſs becomes fertile.

By means of ſand or ſandy Earth, ſtrong loam or clay is fertilized, the Earth being thereby rendered porous, and interſtices or ſpace maintained, by which the juices are prepared, and thrown off into the roots of the plants, and the fibres finds room to extend themſelves.

Sandy or gravelly ground eaſily admits both of heat and moiſture, and are apt to puſh ſeeds and plants much earlier in ſpring than ſtrong loamy or clayey ſoils.

But ſandy land is liable to theſe inconveniencies, that being ſometimes very light and open, it either does not retain a due portion of moiſture, or ſometimes retains it too long, eſpecially where there is clay at bottom; ſo in theſe caſes, is apt either to parch or chill too much.

Loamy Earth.—This is that ſort of Earth which is a mixture of clay and ſand, commonly of a yellowiſh or hazelly colour, and of a ſoft, fat, and ſlippery temperament, not ſo cloſe a texture as clay, nor too looſe and ſandy, but of a middle nature between, and is at all times eaſy to dig and rake, and will readily diſſolve by froſt and rain.

But ſome diſtinguiſh a true loam, or brick-earth, as that which partakes more of clay than ſand.

A good garden loam however ſhould be ſuch a juſt conſiſtence as is pliable to work, and ſuch as will not ſtick obſtinately to the ſpade, rake, and fingers, &c. at every flaſh of rain, nor cruſt or chap in dry weather.

Loamy Earths, anſwering the above deſcriptions, are in many places the moſt common ſuperficial or top Earth, going frequently one, two, or three ſpades deep, and is one of the moſt beneficial ſoils for almoſt all ſorts of plants and trees. See COMPOSTS and LOAM.

Clayey Earth.—Clay is a ſtrong, cold, heavey, moiſt Earth, liable to coaleſce, and gather into a coherent and compact maſs, having but

but little ſpace or interſtice, and Earth thus embodied, and as it were, glued together; does not eaſily give out thoſe ſalts contained in it, nor can the fibres of plants make their way through it in queſt of proper nutriment, and therefore, ſuch a ſoil of itſelf, is no ways diſpoſed to nouriſh vegetables; but if with ſuch an Earth, ſome ſharp indiſſolvable ſand, or ſome other body of ſimilar quality, and light hot dungs be added, and well intermixed by proper digging, and breaking into ſmall particles, they will keep the pores of the clay open, and render the whole looſe and incompact, whereby the juices will have room to aſcend, and the plants thereby receive proper nouriſhment.

All binding Earths, from the loam, till the ſtiffneſs of chalk may be come at, may be reckoned of the clayey kind, and require the aid of light Earths, aſhes, and light dungs to meliorate them for the buſineſs of vegetation.

If the Earth of your garden is of a ſandy looſe temperature, add loam and other heavy ſubſtances by degrees, and a good portion of moiſt rotten dung, particularly the dung of oxen, cows, and hogs, and of old hot-beds, &c. but any good moiſt rotten dung will improve this kind of ſoil.

And if your garden is ſtrong, ſtubborn, loamy, or clayey, meliorate it by ſand, and other light materials, of a fiery, ſprightly nature, together with plenty of dry rotten dung.

EBENUS, Ebony.

It conſiſts of one ſhrubby exotic for the greenhouſe.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, and five-parted at top. COROLLA is papilionaceous, the vexillum roundiſh and erect, the wings ſmall and roundiſh, and ſhort aſcending keel. STAMINA, ten diadelphous filaments, and ſimple antheræ. PISTILLUM, an oblong germen, riſing ſtyle, and ſimple ſtigma. PERICARPIUM, an oval pod, and kidney-ſhaped ſeed.

The ſpecies is,

EBENUS, *Cretica.*

*Cretan Ebony.*] Ebenus with a ſhrubby ſtem, branching three or four feet high, hoary five-lobed hand-ſhaped leaves, and all the branches terminated by thick ſpikes of purple papilionaceous flowers, in June and July, and ſometimes ripe ſeeds in autumn.

It ſhould be kept always in pots, to move to the greenhouſe in winter.

It is propagated by ſeeds ſown in autumn or ſpring, in pots of light earth, which ſhould be placed in a frame during cold weather, and when the plants are two or three inches high, plant them in ſeparate pots, and manage them as other exotics of like quality. See GREENHOUSE PLANTS.

ECHINOPS. Hedge-hog thiſtle, commonly called globe-thiſtle.

This genus furniſhes ſome hardy herbaceous perennials for the pleaſure-ground, producing annual ſtalks, from two to four or five feet high, divided leaves, and terminated by globular heads of flowers.

Claſs and order, *Syngeneſia Polygamia Segregatus.*

*Characters.*] CALIX a polyphyllous, ſcaly general cup, and the partial one of the florets, is oblong, imbricated and perſiſtent. COROLLA, each floret monopetalous, funnel-ſhaped, five-parted at the top, and reflexed. STAMINA, five filaments and cylindric antheræ. PISTILLUM, an oblong germen, ſlender ſtyle, and double ſtigma. PERICARPIUM, none. SEMEN, one oval-oblong ſeed, lodged in the calix.

The principal ſpecies are.

[1]ECHINOPS, *Spherocephalous.*

*Spherical-headed Echinops, or greater Globe-Thiſtle.*] Echinops with perennial roots, upright annual ſtalks four or five feet high, garniſhed with long, jagged, deeply-divided, ſpinous, woolly leaves, white underneath, and the ſtalks ſurmounted by blue flowers, collected into large globular heads in June and July.

*Variety.*] With white flowers.

[2]ECHINOPS *Ritro.*

*Ritro, or Smaller Globe-Thiſtle.*] Echinops with creeping perennial roots, upright ſtrong annual ſtalks two feet high; deeply divided, many-pointed prickly leaves, ſmooth on the upper ſide, and the ſtalks and branches terminated by ſmalliſh globular heads of deep blue flowers.

*Variety.*] With white flowers.

Theſe two perennials and varieties may be employed in large gardens to encreaſe the variety; they will proſper in any ſoil: they are propagated abundantly by ſeed ſown in autumn or ſpring, in any common earth, and raked in: the plants may be tranſplanted into the different compartments.

If the ſeed is ſuffered to ſcatter, many plants will riſe naturally.

EDGINGS. Theſe are ranges of very ſmall dwarfiſh ever-green plants, as box, thrift,

thrift, &c. clofely planted along the edge of borders or beds, ſerving both for uſe and ornament.

Edgings are particularly neceſſary to the edges of ſuch borders or beds as immediately verge walks or alleys of gravel, ſand, ſhells or other looſe materials; and are uſeful to form and preſerve a boundary diſtinction betwixt the borders and walks, and to preſerve the earth of the borders from being forced out upon the walks or alleys, and the ſoil of the walks from the borders; both of which would otherwiſe be the caſe, leſs or more, every time of doing the neceſſary work, and at every hard ſhower of rain: Edgings are therefore particularly neceſſary in flower-gardens, and to the borders immediately verging principal walks, to maintain uniformity and neatneſs, and, conſidered as ornamental, that being evergreen, and if planted in a cloſe neat range along the edge of the border, all of an equal width, not more than two inches broad, and one or two high, and always kept within the compaſs of about three inches in width and height, without gaps and irregularities, but all the way cloſe, and even at ſides and top, they have a pretty effect, whether box or thrift, &c. and as ſome ſorts of plants proper to be employed for Edgings, are of the flowery tribe, ſuch as thrift, daiſies, pinks, &c. they, beſides the property of being evergreen, are very ornamental in their flowers, which, of each ſort, are numerous, and continue ſix weeks or two months in great beauty.

But the beſt Edging in the world is the dwarf ſhrubby box. (*Buxus Suffruticoſus,*) it being the moſt effectual, moſt eaſily kept in order, and the moſt durable, retains its leaves and full verdure at all ſeaſons, proſpers in all ſoils and ſituation, is never hurt by any weather, and will endure many years, always cloſe and regular, with the culture of ſhearing or clipping once or twive every ſummer at top and ſides. See Buxus.

The next to box for Edgings, is thrift, (*Statice Armeria*), which alſo grows very cloſe, low, and in verdure all the year; and flowers beautifully two months in ſummer, but being rather apt to ſpread ſoon out of bounds, requires to be reduced, by cutting in conſiderably on each ſide, or by replanting it a freſh every two or three years; and its general culture as an Edging is, to trim it a little with garden-ſhears on each ſide and top every ſummer, as ſoon as done flowering, cutting off alſo all the withered flower-ſtalks, performing it always in moiſt weather. See Statice.

Daiſies, pinks, catchfly, and ſeveral other low herbaceous evergreen flowery perennials are alſo ſometimes employed for Edgings, which have a pretty effect when in flower; but as in one year they ſpread greatly out of compaſs as Edgings, ſhould be taken up and replanted every ſpring or autumn, but more particularly the daiſies; and the others, if they ſtand longer than one year, ſhould be cut in on each ſide annually after flowering, to preſerve uniformity.

Sometimes ſome ſorts of dwarf buſhy annuals are ſowed for ſummer Edgings in ſmall gardens, ſuch as the dwarf Virginia ſtock, hearts-eaſe, or *viola tricolar*, candy tuft, and ſeveral other low buſhy annual flowers; but the former of them is the moſt ſuitable for an Edging, as it grows low, buſhy, and does not ramble, is very flowery, and continues long in bloom.

Several ſorts of ſhrubby aromatics are alſo uſed for Edgings, as thyme, ſavory, hyſſop, ſage, lavender, and rue, all of which are evergreens, and may be kept low by cloſe ſhearing; but then they become woody, ſtubbed, and naked; but theſe are alſo ſometimes planted as Edgings in kitchen gardens, for oeconomical purpoſes.

Parſley alſo forms a good evergreen Edging, for the edges of the quarters and borders of kitchen gardens; and if the true curled ſort is ſowed, it will be very ornamental, as well as profitable.

As to the method of planting or forming Edgings; if box, the plants are generally planted in ſmall perpendicular trenches, placing them cloſe together, as at once to form a complete Edging. See Buxus. Thrift, daiſies, pinks, &c. are commonly planted by dibble, at about two or three inches diſtance in the line, though, to form a compact Edging at once, they may be planted ſo cloſe as to touch each other; pink Edgings may alſo be formed by ſowing the ſeed in a drill along the edge half an inch deep, ſo ſuffer the plants to remain. Annual flower Edgings are alſo formed in the ſame manner: thyme, ſavory, and hyſſop Edgings may alſo either be formed by ſowing the ſeed, or by plants or ſlips; ſage and lavender, chiefly by planting young ſlips; and rue the ſame, or by ſeed.

All Edgings, the ſhrubby kinds in particular, ſhould be neatly ſhorn or clipped with

with garden-ſhears, at top and ſides every year in ſummer, and ſome ſorts require it twice in that time, to preſerve them perfectly neat, ſuch as box, and moſt other ſhrubby kinds.

Never ſuffer box Edgings to exceed two or three inches in width, nor above three or four high; and thriſt and the other herbaceous Edging to get more than three or four inches wide.

Nor ſuffer the aromatic kinds, if in pleaſure-grounds, to exceed five or ſix inches high, and three or four broad.

For particulars in the different ſorts here mentioned, ſee their reſpective genera.

ELÆAGNUS, Oleaſter or Wild-Olive. It furniſhes two ornamental, deciduous ſhrubs for the ſhrubbery and ſtove, garniſhed with narrow ſilvery leaves, and ſmall apetalous flowers.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX is monophyllous, bell-ſhaped, quadrifid, and the inſide coloured. COROLLA, none. STAMINA, four filaments, and oblong incumbent antheræ. PISTILLUM, a roundiſh germen, ſimple ſtyle, and ſingle ſtigma. PERICARPIUM, an oval drupaceous fruit, incloſing an oblong obtuſe nut.

The ſpecies are,

[1]ELÆAGNUS *Anguſtifolia.*

*Narrow-leaved Oleaſter.*] Elæagnus, with an upright woody ſtem, branching twelve or fourteen high; narrow, ſpear-ſhaped, ſhining, ſattiny leaves, three or four inches long, and ſcarce half an inch broad; and from the axills, ſmall flowers having ſilvery ſtudded cups, yellow within, ſucceeded by ſmall olive-ſhaped fruit.

[2]ELÆAGNUS *Spinoſus.*

*Thorny elliptic-leaved Oleaſter.*] Elæagnus, with an upright woody ſtem, branching twelve or fourteen feet high; elliptical, ſilvery, downy-leaves, two inches long, and near one broad, ſharp thorns under each leaf; and ſmall flowers, having the calix yellow within, ſucceeded by olive-ſhaped fruit.

Both theſe trees merit culture, the firſt for the ſhrubbery, the ſecond for the ſtove; their ſilvery-leaves render them very conſpicuous, and effects a delightful variety.

Their propagation is eaſily effected by layers of their young ſhoots, alſo by cuttings, which will be rooted in one year, and may then be tranſplanted, placing the hardy kinds in the nurſery, to have two or three years growth, when they will be fit for the ſhrubbery.

EPHEDRA, Shrubby Horſe-tail.

There is but one ſpecies, a low ſhrubby ruſhy-leaved evergreen for the ſhrubbery.

Claſs and order, *Dioecia Monodelphia.*

*Characters.*] Male and female flowers on ſeparate plants, the males collected into an amentum; but they rarely flower in England.

The ſpecies is;

EPHEDRA *Diſtachya.*

*Shrubby Horſe-tail.*] Ephedra with a low ſhrubby ſtalk, branching two feet high, having many ſwelling joints, ſending forth oppoſite, narrow ſhoots, branching out into long ruſhy tufts, opening like leaves, there being no other.

This ſhrub may be employed in the fronts of ſmall ſhrubbery clumps; its ſingularity will encreaſe the variety.

It is propagated plentifully by ſuckers or off ſets, ariſing from its creeping roots, which may be tranſplanted in February or March.

EPILOBIUM, Willow-herb, or French Willow.

This genus furniſhes two herbaceous flowery perennials for the full ground, producing annual ſtalks of three or four feet ſtature, narrow leaves, and terminated by long ſpikes of quadripetalous flowers.

Claſs and order, *Octandria Monogynia.*

*Characters.*] CALIX, four oblong, pointed, coloured leaves. COROLLA, four roundiſh cruciforme petals. STAMINA, eight filaments alternately ſhorter, and compreſſed antheræ. PISTILLUM, a long cylindric germen under the corolla, ſlender ſtyle, and quadrifid revolute ſtigma. PERICARPIUM, a long, cylindric, furrowed, quadrilocular capſule and oblong ſeeds crowned with down.

The ſpecies are.

[1]EPILOBIUM *Anguſtifolium.*

*Narrow-leaved Epilobium.*] Epilobium with very creeping perennial roots, upright flower-ſtems, branching erectly four feet high, long ſpear-ſhaped leaves placed irregularly, and all the branches and main ſtem, terminated by long erect ſpikes of purple flowers, of very ornamental appearance.

*Varieties.*] With white flowers,—white purple-ſtriped flowers—with broad leaves and white flowers.

EPILOBIUM *Hirſutum.*

*Hairy Epilobium.*] Epilobium with very creeping perennial roots, upright hairy ſtalks, branching erectly, three feet high, ſpear-ſhaped, ſawed, decurrent, hairy leaves placed oppoſite, and all the branches and main ſtem terminated by erect ſpikes of purple flowers.

Both theſe ſpecies of *Epilobium* grow naturally in ſhady moiſt places in many parts of Britain, &c. the firſt are inhabitants of ſhady woods, the other, the ſides of watery ditches, and are great ramblers both by root and ſtalks; but being ornamental in their mode of flowering, have been long admitted into gardens to encreaſe the collection of flowery perennials, and are good furniture for large borders, but are peculiarly adapted for ſhady moiſt places; they flower abundantly in July and Auguſt, continuing a month or ſix weeks.

They obtained the name of willow-herb from the great reſemblance of their leaves to thoſe of the willow.

Both ſpecies are propagated in great plenty by their creeping roots, in ſpring or autumn, which may be divided and planted at once, where they are to remain, and they will flower at their uſual ſeaſon.

EPIMEDIUM, Barrenwort.—It furniſhes one low herbaceous flowery perennial.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX, tetraphyllous and deduous. COROLLA, four cruciform oval petals, and four large cup-ſhaped nectariums. STAMINA, four filaments, and bilocular antheræ. PISTILLUM, an oblong germen, ſhort ſtyle, and ſimple ſtigma. PERICARIUM, an oblong unilocular capſule and many oblong ſeeds.

The ſpecies is,

EPIMEDIUM *Alpinum.*

*Alpine Epimedium.*] Epimedium with creeping perennial roots, crowned by many ſtalks eight or nine inches high, dividing at top by threes, each diviſion garniſhed with heart-ſhaped ſtiff folioles, and flower-ſtalks ſix inches high, dividing into ſmaller, each ſupporting three reddiſh cruciform flowers in May.

It delights moſt in ſhady borders, and may be propagated at pleaſure by its creeping roots.

ERYNGIUM, Eryngo, or Sea Holly.

This genus compriſes ſeveral hardy, herbaceous, flowery perennials, producing ereſt ſtalks, from one to three feet high; ſimple, entire, and divided prickly leaves; and the ſtalks terminated by roundiſh aggregate heads of quinquepetalous flowers.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, a conical receptacle, common to many florets, having a five-leafed general involucrum, and each floret a pentaphyllous calix coloured above. COROLLA, each floret is of five inflexed petals, collected into a roundiſh uniform head. STAMINA, five filaments and oblong antheræ. PISTILLUM, hairy germen, two ſtyles, and ſimple ſtigmas. PERICARPIUM, an oval two-parted fruit to each floret, having each one taper ſeed.

The principal ſpecies are:

ERYNGIUM *Maritimum.*

*Maritime Eryngo, or Sea Holly.*] Eryngium with creeping, penetrating, fleſhy, perennial roots crowned by roundiſh, plaited, ſtiff, ſpinous-edged leaves, and between them upright ſtalks a foot high, garniſhed with ſmall roundiſh leaves, and terminated by roundiſh heads of whitiſh blue flowers.

ERYNGIUM *Amethyſtinum.*

*Amethyſtine-coloured Eryngo.*] Eryngium, with perennial roots, crowned with trifid, hand-ſhaped, many-pointed leaves, ſomewhat pinnated at the baſe; upright ſtalks two feet high, garniſhed with many-parted ſpinous leaves, and terminated at top by roundiſh heads of amethyſtine or purple violet-coloured flowers.

*Variety.*] With pale amethyſtine heads of flowers.

ERYNGIUM *Planum.*

*Plane leaved Eryngo.*] Eryngium with downright perennial roots, crowned with oval plane leaves, crenated on the edges, upright blue ſtalks two or three feet high, garniſhed with many-pointed ſpinous leaves, and terminated at top by oval heads of amethyſtine blue flowers.

*Variety.*] With ſtalks white upward, and white heads of flowers.

ERYNGIUM *Alpinum.*

*Alpine Eryngo.*] Eryngium with perennial roots, crowned with oblong heart-ſhaped leaves, upright ſtalks branching each way two or three feet high, adorned with deeply divided, many-pointed leaves, all ending in ſpines, and all the branches and main ſtalk terminated by conical light blue heads.

ERYNGIUM *Aquaticum.*

*Aquatic American Eryngo.*] Eryngium with perennial roots, crowned with long ſword-ſhaped, ſtiff, ſawed, ſpinous leaves a foot long, and between them an upright ſtalk two feet high, terminated by oval, whitiſh-blue, heads of flowers.

All theſe ſpecies of *Eryngium* are hardy perennials, the root durable, but annual in ſtalk; the firſt of which is a maritime plant, growing naturally on the ſea ſhores in many parts of Britain, &c. the ſecond, third, and fourth inhabit mountainous places of the continent;

tinent, and the fifth is of America; all of which are retained in curious gardens, as plants of ſingularity and ornament.

The flowers of all the ſorts are collected into cloſe roundiſh heads at the top of the ſtalks, each head compoſed of many florets. See the *Characters*.

They all flower principally in July, and the ſeeds ripen in September.

All the ſorts ſucceed in any of the borders, or other compartments, though the firſt ſort is the moſt proſperous in gravelly or ſandy ſoils.

They are propagated by ſeeds, ſowed either in autumn or ſpring, in a bed or border, and raked in, the autumn ſowing generally comes up ſtrongeſt in ſpring following; and in autumn after tranſplant the plants into the places where they are to remain to flower.

ERYTHRINA, coral-tree (*Corallodendron.*)

This genera conſiſts of ſhrubby, flowery, exotics for the ſtove, adorned chiefly with trifoliate, or three-lobed leaves, and ſcarlet ſpikes of papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX is monophyllous, tubular, and entire. COROLLA, is papilionaceous, and of five petals, the ſtandard ſpear-ſhaped and very long; the wings oval and ſhort; and the keel dipetalous. STAMINA, ten diadelphous filaments, and arrow-headed antheræ. PISTILLUM, a pediculated ſubulate germen, and ſtyle, and ſimple ſtigma. PERICARPIUM, a long ſwelling, unilocular pod, and kidney-ſhaped ſeeds.

The principal ſpecies:

[1]ERYTHRINA *Corallodendrum.*

*Corallodendron, or Smooth Coral-tree.*] Erythrina with a tree-like woody ſtem, branching irregularly ten or twelve feet high, ſmooth trifoliate leaves, having heart-ſhaped lobes, and from the ends of the branches ſhort thick ſpikes of beautiful ſcarlet flowers.

[2]ERYTHRINA *ſpinoſa.*

*Spinous Coral-tree.*] Erythrina, with a tree-like woody ſtem, branching ten or twelve feet high, armed with ſpines, trifoliate prickly leaves, and red ſpikes of flowers.

[3]ERYTHRINA *picta.*

*Black thorned Coral-tree.*] Erythrina with ſhrubby ſtalks, dividing into branches, five or ſix feet high, ſtrongly armed with black ſpines; trifoliate ſmall leaves, and pale ſcarlet ſpikes of flowers.

[4]ERYTHRINA *herbacea.*

*Herbaceous Erythrina.*] Erythrina with a thick woody root, ſending up herbaceous ſtalks annually in ſpring, two feet high, garniſhed below with trifoliate narrow-pointed leaves, and terminated by long ſcarlet ſpikes.

All theſe plants being natives of hot countries, in Africa and America require the conſtant ſhelter of a ſtove in England, ſo muſt always be kept in pots, and retained in that department.

They flower here in our ſtoves, in ſummer are extremely beautiful, but are not ſucceeded by ſeeds in this country.

All the ſorts are propagated by ſeed, which are annually imported hither from Africa and America. Sow them half an inch deep in pots of light rich earth, which plunge in the bark-bed of the ſtove, &c. and when the plants are two inches high, prick them in ſeparate ſmall pots, plunging them alſo in the bark-bed; give frequent waterings, and as they encreaſe in growth ſhift them into larger pots.

ERYTHRONIUM, Dog's Tooth.

*(Dens Canis.)* or Dog's Tooth Violet.

The plants are low, herbaceous, flowery perennials for the full ground, riſing four or five inches high, terminated by hexapetalous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, ſix oblong petals, reflexed and ſpread open to their baſe. STAMINA, ſix ſhort filaments and oblong antheræ. PISTILLUM, a turbinated germen, ſimple ſtyle, and triple ſtigma. PERICARPIUM, a ſub-globoſe trilocular capſule, and many oval flat ſeeds.

There is but one ſpeces, which however, admits of ſeveral varieties, all of the flowery tribe.

The ſpecies is,

ERYTHRONIUM *Dens Canis.*

*Dog's Tooth,* (*Dens Canis.*) Erythronium with oblong, tooth-ſhaped, fleſhy, white perennial roots, crowned by two oval, purple and white ſpotted leaves, united at their baſe, and between them, an upright naked purple ſtalk, four inches high, terminated by one drooping flower, having ſix ſpear-ſhaped reflexed petals, of different colours in the varieties.

*Varieties are.*] Dog's Tooth with white flowers—with purple flowers—with pale red flowers—dark red flowers—crimſon flowers—yellow flowers, but rare—and dog's tooth with narrow leaves and flowers of the above colours.

All theſe varieties are hardy, durable in root, but annual in leaf and ſtalk, which riſe early in ſpring, and flower in April, but rarely furniſh good ſeeds in England; they may be all employed to adorn the fronts of

borders,

borders, planting them in ſmall patches, in which they will make a good appearance.

Their propagation is by off-ſets from the roots, when their leaves decay, from June till September.

ESPALIERS, ranges of dwarf fruit trees, trained to a trillage of wood-work in ſuch order as to form a kind of hedge.

Eſpaliers are commonly arranged in a ſingle row round the boundaries of the quarters or principal diviſions of the kitchen garden, there ſerving a double or treble purpoſe, both profitable, uſeful, and ornamental; they produce plentifully of large fine fruit, without taking up much room, or any ways incommoding the ground, and being in a cloſe range, hedge-like, they wonderfully ſhelter the eſculent crops in the quarters; and having borders immediately under them on each ſide, afford different aſpects for different plants, as they ſhall require at different ſeaſons of the year; as in the winter for ſhelter; the ſpring for forwardneſs; and the ſummer for ſhade; and as to the ornament and variety, what can be more delightful in ſpring, in the excurſion of the walks, than the charming appearance the trees make when covered with their ſnowy bloom, differing in themſelves, in thoſe of different genera, ſpecies, and varieties; in ſummer, to ſee the fruit of the different ſorts advancing gradually to perfection; and in autumn, how pleaſing to find the various kinds arrive ſucceſſively at maturity: and as the trees are arranged all of an equal height, not exceeding ſix or ſeven feet, cloſely furniſhed with branches ranged at regular diſtances one above another, from the very ground upward, the fruit hereby exhibits itſelf to great advantage, and being low, and the branches fixed, is not liable to be blown down by wind.

An Eſpalier has this advantage over a wall tree, that it has liberty to form branches or fruit ſpurs on both ſides, which in the wall-tree cannot be effected but on one.

The ſorts of fruit uſually employed to form Eſpaliers, are principally apples, pears, and plums; but ſeveral other ſorts may alſo be uſed to encreaſe the varieties, as quinces, apricots, cherries, almonds, mulberries, vines, figs, filberds, &c.

Obſerve always however, to contrive all thoſe trees in the ſame line or range, that are nearly of the ſame growth, for the ſake of uniformity.

They ſhould be planted principally on thoſe borders ſerving as the immediate outer boundary to the quarters of the kitchen garden, and immediately verging the principal walks; they may alſo be planted in pleaſure grounds, &c. if thought convenient. The width of the borders may be about ſix feet, and the line of Eſpaliers placed four feet at leaſt, from the outer edge, and eighteen or twenty diſtant in the row, eſpecially for apples, pears, and plums, though twenty-five feet is not too much; but the trees planted at that diſtance, taking a long time before they approach each other to fill the Eſpalier, they appear ſtraggling and irregular, that few perſons plant them more than eighteen or twenty feet aſunder; if however they are planted only fifteen or eighteen feet diſtance, they will meet and form a cloſe Eſpalier ſooner by ſome years, and when they begin to interfere and incommode each other, the interfering branches of every other tree may be gradually cut away annually in winter-pruning, to give the intermediate trees room to advance and meet each other, and at laſt the others may be taken quite away, and the remaining trees ſtanding at thirty or ſix and thirty feet diſtance will have full ſcope to ſpread.

*Their general training and planting.*

All trees intended for Eſpaliers, that are propagated by grafting and budding, ſhould be grafted or budded within ſix inches of the ground, to procure lower branches to furniſh the Eſpalier, quite from the bottom regularly upward; and the firſt ſhoots from the graft or bud, ſhould alſo in ſpring, when a year old, be headed down within five or ſix inches of the graft, to force out a ſupply of five, ſix or more good ſhoots at that part, for the reaſon juſt mentioned; and whether the trees are then in the nurſery or planted in the Eſpalier, its ſhoots or branches ſo obtained, ſhould, the ſame ſummer or autumn, when eighteen inches or two feet or more long, be trained along as they advance to ſtakes placed for that purpoſe, laying the ſhoots to the right and left horizontally in the poſition proper to give them the firſt neceſſary form as Eſpalier-trees; if the trees are raiſed in nurſeries for ſale, the above practice is eligible, whereby the trees are rendered more ſaleable, and their value encreaſed; and if the firſt heading does not furniſh the ſupply of lower branches required, you may practiſe a ſecond heading, either in whole, or only ſome of the middle-moſt ſhoots, as you ſhall judge neceſſary; afterwards they muſt be trained all principally at full length.

When the trees in the nurſery are from two

to four or five years old from the graſting or budding, being furniſhed with ſix, eight, ten, or more good branches near the bottom, properly ſituated for ranging two ways, according to the line of the Eſpalier, they are then fit for planting out finally for that purpoſe, obſerving the diſtances as before-mentioned. If apples and pears upon dwarf ſtocks, fifteen or eighteen feet may be ſufficient; but if upon free ſtocks, twenty-one feet at leaſt is neceſſary: plums ſhould alſo be planted eighteen feet diſtance at leaſt, in the line; cherries, apricots, figs, mulberries, vines, &c. never leſs than fifteen diſtance, but if eighteen the better: as ſoon as they are planted, place ſtakes, ranging the way of the row, and to which tie the branches with oſier twigs, thoſe of each tree horizontally to the right and left, keeping an equal number on each ſide, at ſix or eight inches diſtance one above another, and at full length; except a farther ſupply of more branches may be wanting, to furniſh the bottom and middle of the tree, then ſhortening is to be practiſed according to the rules afore-mentioned, to obtain the proper ſupply; afterwards train all the branches at full length, till all thoſe of each tree meet, and all redundant ſhoots more than the allotted horizontals are to be diſplaced.

Another method of forming Eſpaliers, ſometimes practiſed, is, after having headed down the firſt ſhoots, as above ordered, and ſuppoſe the trees in conſequence furniſhes about three bottom ſhoots, the two ſide ones are trained horizontally, the way of the Eſpaliers, and the middle one is trained upright; if five ſhoots, two muſt go to each ſide, and the middle one perpendicular: this perpendicular ſhoot muſt ſtill be directed upwards, to furniſh more lateral ſhoots for horizontals, which muſt be trained horizontally to each ſide, as above, ſtill continuing your upright in the middle; obſerving however, if the upright ſhoot ſhould not throw out horizontals low enough, it ſhould be ſhortened, whereby it will furniſh freſh ſhoots at any deſired height, two or four of which, according to the number produced, are to be uſed for horizontals, and one ſtill directed up the middle for a ſtem, and ſo continue encreaſing your number of horizontals annually, ranging from each ſide of the ſtem, at ſix or eight inches one above another, from bottom to top of the Eſpalier.

In planting Eſpaliers, in reſpect to the treillage for training the branches upon, you may either only place four or ſix common ſtakes to each tree, in a line, juſt to train the branches the firſt two or three years, till the trees are ſomewhat advanced; then taking theſe away, form a regular treillage-work, as directed below; or if you are anxious to preſerve uniformity, a general treillage may be formed at once, at firſt planting of the trees.

Theſe treillage-works for the above purpoſe, may be of different degrees of taſte for uſe and ornament, according to your fancy or convenience: the cheapeſt and the ſooneſt made, is that of ſtraight ſtakes driven into the ground a foot diſtance, and ſawed level at top, five or ſix feet high; and ſlips of deal, or poles arranged along the top the whole length, and ſo train the branches of the trees along, from ſtake to ſtake.

But for the ſake of ornament, a regular frame or treillage may be formed of ſquare timbers, and to have it more durable, the principal poſts might be of oak, two or three inches ſquare, and rails carried from poſt to poſt, the firſt about eighteen inches from the bottom, one at top, and a third in the middle ſpace; then thin ſquare ſlips of lath, or ſmall aſhen poles, or the like, are fixed upright to the rails on the ſide next the trees, a foot aſunder, and paint the whole with oil-colour, to render it more ornamental and durable.

To either of the above treillage-work, the Eſpalier-trees are to trained in a regular manner, bringing the lowermoſt branches down horizontally within eight or ten inches of the ground, tying them to the uprights of the treillage; the next courſe ſix or eight inches above theſe, in the ſame poſition; the ſame of the next and every ſucceeding courſe all the way up, preſerving an equal number on each ſide, ranging exactly in the ſame horizontal poſition, and diſtance from bottom to top, training them always along at full length, except, as aforeſaid, there be a want of wood in any part; then, to force out the ſupply wanted, ſhorten ſome contiguous ſhoots to five or ſix inches, either the ſame ſummer it is produced, in June, otherwiſe not till ſpring following, and ſo continue every year encreaſing the number of horizontals, and place them properly till the trees are furniſhed with branches one above another, from bottom to top of the treillage.

*Their general pruning.*

As to the general pruning of Eſpalier-trees, obſerve for one thing, the branches are for the general part to be trained always at full length, for ſhortening more than juſt

neceſſary

neceſſary to procure an occaſional ſupply of wood, would not only produce a confuſion of branches, but as the trees always produce their fruit upon ſpurs, as obſerved in the article DWARF TREES, which, if the branches are trained at full length, generally firſt form themſelves toward the upper part, and gradually along the ſides at each eye; that by ſhortening, it would cut away the ſaid firſt fruitful parts, and from the lower eyes, that inſtead of forming ſpurs, force out ſtrong unneceſſary wood, and ſcarce any fruit; and this is the reaſon we ſee ſo many ill-formed Eſpalier-trees, many people thinking ſhortening the ſhoots is neceſſary to ſtrengthen them as they call it, and hereby the tree throws out vaſt quantities of wood every ſummer, which they either then, or in winter, or ſpring pruning, cut out, generally leaving a ſtump of each ſhoot about an inch or two long, and from every eye of theſe ſtumps, more ſtrong ſhoots riſe the year following, and theſe are alſo ſtumped off in the ſame manner, and ſo they continue from year to year, by which means the tree is filled with large cluſtering ragged ſpurs, formed entirely of the ſtumps of ſhoots: therefore, always keeping in mind to continue all the ſhoots and branches principally at full length; and when neceſſary, to cut out any ſuperabundant wood, always take it off quite cloſe, never leaving any ſtump, and conſtantly encourage the fruit ſpurs, which are natural ſhoots of from about half an inch to one or two in length; obſerving however, when any of theſe are worn out, or grown cankery, or become very long, as to project conſiderably foreright, they ſhould be cut out cloſe, to make room for thoſe of better growth.

Eſpaliers ſhould have two principal dreſſings annually, i. e. ſummer and winter pruning.

In ſummer the trees often produce numbers of ſhoots more than are wanted, or that can be trained in; therefore, keeping in mind the proper diſtances and general poſition of the neceſſary branches to form each tree, begin early in June, and clear off all ſuperfluities, as they are produced, that is, all ſore-right ſhoots iſſuing from the front and back of the branches; and thoſe of very luxuriant growth, ſhould always be diſplaced, rubbing or cutting them off cloſe; not however reducing any of thoſe ſhoots produced immediately from the end of the branches, which muſt be left entire, to extend the branch in length, and form a further ſupply of fruit-ſpurs. All other ſhoots, however good and well placed, ariſing from the ſides of the horizontals, and that are evidently ſuperabundant, i. e. more than what can be trained in, conſiſtent with the allotted diſtances, and regular poſition of the general horizontals or bearing-branches, ſhould alſo be taken off; obſerving however, to preſerve here and there a good ſhoot towards the lower part of the branches, in the moſt vacant ſpaces, or where bad branches occur, training them up between at full length till winter pruning; and if then not wanted, may be cut out: for it is neceſſary always, at any rate, to leave ſome as a reſerve till winter, in caſe of any unforeſeen vacancy happening. In the above manner go over the Eſpalier-trees of all ſorts twice every ſummer at leaſt, the firſt time early in June as aforeſaid, and again in July. In the firſt dreſſing in June, which if there are any vacancy want filling, you may pinch any contiguous ſtrong young ſhoot of the year, to three or four eyes, whereby it will furniſh the like number of ſhoots the ſame ſeaſon, which you may train into the vacant ſpace.

The above ſummer dreſſings are not only beneficial to the trees, but, clearing out uſeleſs wood, admits the ſun and air to effect the growth and ripening of the fruit.

In performing the ſummer dreſſings, if you begin betimes, before the young wood becomes long and woody, all redundances may be rubbed off cloſe by hand; but if the ſhoots are firſt ſuffered to be of conſiderable length, and hardened, the knife muſt be uſed, always rubbing or cutting cloſe.

Winter pruning. This may be performed any time from the fall of the leaf in November till March; in this pruning, a general regulation is to be obſerved both to old and new branches when neceſſary, therefore examine firſt the ſtate of all the main horizontals, if any are decayed, or much cankered, take them out, either to their origin, or to ſome healthful young branch ariſing from them below the defect; likewiſe any old naked branch, not furniſhed with bearing ſpurs, nor ſupport-branches, that are, ſhould alſo be cut out, where there are large cluſtering ragged ſpurs, formed by the remaining ſtumps of ſhortened ſhoots as before obſerved; cut them alſo off cloſe, being careful to preſerve all the natural fruit-ſpurs already deſcribed. Examine alſo ſuch young ſhoots that were trained up in the ſummer dreſſing, ſuch of them that

are well placed, and towards the lower parts of the main branches, and are likely to be wanted to fill any preſent or future vacancy, are to be left and trained up regularly at full length; for it is neceſſary always to have ſome young branches in training between the principal ones, in different parts, where you ſhall judge neceſſary, without crowding, to be coming forward gradually to a bearing ſtate, to ſupply the place of ſuch as are apparently in a decaying ſtate, or but bad bearers; all other young ſhoots left in ſummer, that are not wanted for the above purpoſe, ſhould now be cut out cloſe, obſerving, as in the ſummer pruning, that all ſhoots ariſing ſingly, immediately from the ends of the horizontals, muſt now alſo be left entire, that is, leaving only one to each branch as a leader, and to extend the reſpective branches in length, to fill the extent of Eſpalier allotted; ſo that every branch and ſhoot ſo reſerved for training in, muſt, except in caſe of a vacancy, alſo ſtill be continued along at full length, they will then naturally form fruit-ſpurs at almoſt every eye or bud all along their ſides.

For the branches of apples, pears, plums, cherries, &c. always produce their fruit upon ſpurs, which generally begin to form when the branches are two or three year old, provided the branches are left entire, but if ſhortened, they never form properly.

Having winter-pruned the trees, you muſt then proceed to freſh tye all the horizontals, old and new, in a neat manner to the treillage, ſtill preſerving nearly an equal number on each ſide of every tree, and all at regular diſtances of ſix or eight inches, and their poſition ſo much horizontal, as their extremities may not be above ſix or eight inches higher than the bottom parts, training every branch as ſtraight as an arrow, clean from the bottom to the extremity, tying them neatly to each upright of the treillage.

The beſt material for tying the branches of Eſpaliers, is oſier, chuſing the ſmall twigs of about eighteen inches, or two feet long, which, if you have none of your own growing, may purchaſe them cheap enough at the baſket-makers, the yellow oſier is the beſt if it can be obtained. See SALIX.

The mode of tying is, put the twig around behind the treillage, keeping the biggeſt end faſt, bring the other end round the branch, to meet it, twiſting it about the big end once or twice, cloſe to the branch, and turn the point in betwixt that and the tying, draw it tight, then cut both ends even, to about an inch; in this manner every branch muſt be tyed to all the uprights of the treillage its length reaches.

EVER-GREENS, *(Sempervirens.)*

All ſorts of trees, ſhrubs, and herbaceous plants that retain their green leaves the year round, may be denominated Ever-greens, though it is moſt commonly underſtood of trees and ſhrubs, of which there are great numbers in our gardens and plantations, employed both for ornament, variety, and as foreſt trees for timber, many of which are adapted to grow in any part of the habitable world, and in general their leaves are harder and leſs ſucculent than thoſe of deciduous trees; they are not in the leaſt influenced by the clemency or inclemency of ſeaſons, but preſerve them in conſtant verdure through the year; the old leaves remaining a long time after the formation of the new ones, and do not drop them at any determinate time.

Many herbaceous perennials enjoy the ſame privilege with the Ever-green trees in retaining their leaves, and reſiſt the ſeverities of winter; ſome even can diſpenſe with earth for ſome conſiderable time, ſuch are the houſe-leeks, navel-worts, aloes, &c. being replete with juices, which the leaves imbibe from the humidity of the atmoſphere, ſufficient for effecting the purpoſes of vegetation.

Notwithſtanding all the principal Ever-green trees and ſhrubs are fully treated of, as they occur in the courſe of this work, we think it eligible to collect into one point of view, a liſt of all the principal ſorts commonly cultivated in the nurſeries for ſale, and which are proper for uſe and ornament in gardening.

In this place however we ſhall only exhibit the hardy ſorts; for the others, ſee GREEN-HOUSE, HOT-HOUSE, &c.

Each ſort is arranged according to its *generical* title, viz.

ARBUTUS, or ſtrawberry-tree—common Arbutus, with oblong fruit—with round fruit—with red flowers—double bloſſom common Arbutus—oriental Arbutus, or andrachne—curled-leaved andrachne.

ARTEMISIA, Mugwort—tree wormwood.

ATRIPLEX, ſee purſlane-tree,—broad-leaved—narrow-leaved.

BUPLEURUM, ſhrubby Æthiopian hart-wort.

BUXUS, the box-tree—broad-leaved tree box—narrow-leaved—gold-ſtriped—ſilver-ſtriped—gold-edged—curled-leaved ſtriped—dwarf ſhrubby box.

CELASTRUS, ſtaff-tree—Virginia upright celaſtrus—climbing celaſtrus.

CISTUS, rock-roſe—poplar-leafed—willow-leafed—bay-leafed—waved-leafed—round-leafed—ſea purſlane-leafed—oblong white-leafed—hoary-leafed—Montpelier white gum ciſtus—ladaniferous ciſtus—Cretan ciſtus.

CLEMATIS, virgins bower—Ever-green Spaniſh climber.

CNEORUM, widow-wail, but one ſort.

CUPRESSUS, cypreſs-tree—common cypreſs, with upright branches—with ſpreading branches—with ſmall fruit—blue-berried cypreſs.

CYTISUS, tree trefoil—Ever-green Neapolitan cytiſus.

DAPHNE, ſpurge-laurel—common ſpurge-laurel—variegated ſpurge-laurel.

EPHEDRA ſhrubby horſe tail, but one ſort.

EUONYMUS, ſpindle tree—Ever green ſpindle-tree.

HEDERA, ivy-tree—common ivy-tree—yellow-berried—gold-ſtriped—and ſilver-ſtriped common ivy.

ILEX, the holly-tree—common; of which there are the following varieties—Common green prickly-leafed—ſmooth green-leafed—green-leafed yellow-berried—box-leafed—gold-ſtriped common prickly-leafed—ſilver-ſtriped common prickly-leafed—gold-ſtriped ſmooth-leafed—ſilver-ſtriped ſmooth-leafed—narrow-leafed ſtriped—cream-coloured ſtriped ſawed-leafed—hedge-hog-leafed, having the whole ſurface covered with ſhort ſpines, of which there are, green hedge-hog—ſilver-ſtriped hedge-hog—gold-ſtriped hedge-hog—and ſilver-edged hedge-hog—blotched-leafed yellow-berried—Hertfordſhire white leafed—copper-coloured; with ſeveral other leſs material varieties—Dahoon broad-leafed holly.

JUNIPERUS, Juniper tree—common juniper—taller Swediſh common juniper—Spaniſh large-berried juniper—red Virginia and Carolina cedar—Bermudas cedar—Phœnician cedar—Lycian cedar—great cypreſs-leaved Jamaica cedar. Savins, ſpreading ſavin—upright ſavin—ſtriped ſavin: all the above are ſpecies and varieties of *Juniperus*.

KALMIA, broad-leafed—narrow-leafed.

LAURUS, bay-tree—common bay—broad-leafed—narrow-leafed.

LIGUSTRUM, privet—Ever-green privet.

PHLOMUS, Jeruſalem ſage-tree—broad-leafed yellow phlomus—narrow-leafed yellow phlomus—purple phlomus, or Portugal ſage-tree.

PINUS, pine-tree, fir-tree, and cedar of Lebanon:—pine kinds are, wild pine, called Scotch fir—pineaſter, or long-leafed wild pine—Weymouth pine—great-coned ſtone pine—long three-leafed ſwamp pine—cembro pine—frankincenſe large-coned pine—dwarf pine:—fir kinds are, ſilver yew-leafed fir—Norway ſpruce fir—Newfoundland white ſpruce fir—Newfoundland black ſpruce fir—Newfoundland red ſpruce fir—hemlock fir—long-coned Corniſh fir—balm of Gilead, or ſweet-ſcented fir—oriental fir—cedar of Lebanon.

LONICERA, honey-ſuckle—Ever-green honey ſuckle.

MAGNOLIA, Ever-green magnolia, called laurel-leafed tulip-tree.

MEDICAGO, moon trefoil—ſhrubby, hoary, Ever-green medicago.

MESPILUS, the medlar—Evergreen meſpilus, pyracantha, or Ever-green thorn.

PHILLYRIA, mock privet—the common, oval-leaved, privet-leafed, and olive-leafed—the broad-leafed, with ſmooth leaves, prickly-leafed, and ſawed-leafed—the narrow-leafed, with roſemary-leaves, lavender-leafed, and ſtriped-leafed.

PRINOS, winter berry—Ever-green winter berry, Yappon, or South-ſea thea, formerly *Caſſine*.

PRUNUS, plum-tree—Ever-green prunus, or laurel-tree; of which are, common green laurel—gold-ſtriped laurel—and ſilver-ſtriped laurel—Portugal laurel.

PYRUS, pear-tree—Ever-green ſweet-ſcented Virginia crab-tree.

QUERCUS, oak-tree, and cork-tree—common Ever-green oak, with broad leaves, narrow leaves, and holly-leafed—cork-tree with broad leaves, and narrow leafed—dwarf kermes oak—live oak.

RHAMNUS, including alaternus and buck-thorn—common alaternus—broad-leafed alaternus—jagged-leaved alaternus—blotched-leafed alaternus—gold-ſtriped-leafed alaternus—ſilver-ſtriped alaternus—Ever-green buck-thorn with narrow leaves—olive-leafed.

RHODODENDRON, dwarf roſe bay.—The common dwarf-roſe bay—large American.

ROSA, roſe-tree—Ever-green roſe.

RUSCUS, butchers broom—common myrtle-leafed, prickly butchers broom—broad-leafed hypogloſſum, or tongue-upon-tongue laurel, Alexandrian laurel.

SALSOLA, ſtone-crop-tree, formerly *Chenopodium*.

TAXUS

TAXUS yew-tree—common yew-tree—ſhort-leafed—variegated-leafed.

THUYA, *Arbor Vitæ*, or tree of life—common arbor vitæ—Chineſe arbor vitæ—American ſweet-ſcented—variegated.

VIBURNUM, *Lauruſtinus*—common lauruſtinus—broad-leafed—hairy-leafed—ſhining-leafed—white-ſtriped-leafed—yellow-ſtriped-leafed.

ULEX, furze, gorſe, or whins—common wild furze—white-flowered—long narrow-ſpined—ſhort-ſpined—large French furze—dwarf-furze.

All the above liſt of Ever-green trees and ſhrubs, are ſo hardy, that they proſper in almoſt any common ſoil and ſituation: ſeveral of the large ſorts may be employed both as foreſt trees, and for ornament, and the ſorts in general are choice furniture for all kinds of ſhrubbery works, which, for the general part ſhould be ſtationed in clumps or plantations by themſelves, and not too generally intermixed with trees of the deciduous tribe, except here and there one towards the fronts of clumps, and borders of principal plantations, where they may be conſpicuous; but they have a fine effect when they are ſtationed in clumps alternately with thoſe of the deciduous kinds, either on the boundaries of grand lawns, or any other principal part of pleaſure-grounds, parks, or fields, or ſides of hills, &c.

Theſe plants, both of the tree and ſhrub kind, in all plantations, whether in ſmall or large clumps, or in any running ſhrubbery works, ſhould all be ſuffered to retain their natural growth, only juſt to cut out or ſhorten any very rambling or irregular ſhoot or branch, and broken and decayed wood.

Formerly hedges of Ever greens were in great eſtimation for purpoſes of ornament, but the prevailiug taſte of rural deſigns in gardening has almoſt aboliſhed every thing of that kind from the Engliſh gardens; Ever-greens were alſo in great repute for effecting various pieces of rural architecture, both in hedges and other works, forming cabinets, pavillions, porticoes, pilaſters, niches, arcades, cornices, pediments, amphitheatres, and various other figures, which in ancient gardening were often ſo arranged, and curiouſly trained, as to effect an air of grandeur and art, but becoming at laſt too general, and ſo predominant, that ſcarce any thing elſe was to be ſeen, the taſte created diſguſt, and is now almoſt univerſally ſupplanted by the introduction of deſigns entirely rural; though, for the ſake of variety, ſomething of theſe regular works might ſtill be admitted with propriety in ſome particular parts of large pleaſure-grounds, which, if judiciouſly diſpoſed, not to obſtruct views, &c. they may be uſeful both to effect variety and ornament, in contraſt with rural deſigns, as well as afford an opportunity for the gardener to diſplay his ingenuity in ſuch kind of works.

The ſorts of Ever-greens commonly uſed for the above kind of work in hedges, &c. are yew, holly, phillyrea, alaternus, lauruſtinus, and Ever-green oak; ſometimes laurel, bay, tree-box, pyracantha, ſea purſlane ſhrub, juniper, Virginia cedar, and roſemary; but yew and holly are ſuperior for any general work, they growing very cloſe and firm, and always retain their poſition, though, ſeveral of the other ſorts appear very beautiful in any kind of hedge-work, particularly the phillyrea, alaternus, lauruſtinus, Ever-green oak, and laurel; but for ſingle detached figures, yew is the beſt calculated, ſometimes holly, and the tree-box is alſo uſed for that purpoſe.

All hedge-work and figures of any of the above kind, ſhould always be clipped once every ſummer at leaſt; but, to have them perfectly neat, ſhould have that operation performed twice, the firſt in June, and the ſecond in Auguſt. See HEDGES.

EUONYMUS, Spindle tree.

This genus furniſhes two hardy deciduous and ever-green flowering ſhrubs for the ſhrubbery, of ten or twelve feet ſtature, ornamented with ſimple leaves, and bunches of ſmall pentapetalous white flowers.

Claſs and order, *Pentandria Monogynia.*

*Characters.*] CALIX is monophyllous, and five-parted. COROLLA four or five oval, plane ſpreading petals. STAMNIA, five ſhort filaments, and twin antheræ. PISTILLUM, an acuminated germen, ſhort ſtyle, and obtuſe ſtigma. PERICARPIUM, a ſucculent pentagonous, quinquangular, quinquelocular, coloured capſule, having one oval ſeed in each cell.

There are but two real ſpecies, viz.

1 EUNONYMUS *Europæus.*

*European deciduous Spindle tree.*] Euonymus with an upright woody ſtem, dividing into many branches, riſing ten or fifteen feet high, garniſhed with oblong oppoſite leaves; and from the ſides of the branches, ſmall bunches of greeniſh quadrifid flowers, ſucceeded by pentagonous capſules, diſcloſing their ſeeds in a beautiful manner in autumn.

*Varieties.*] Narrow leaves and deep red berries—with pale red berries—with white berries—with broad leaves—with variegated leaves.

[2]EUONYMUS *Americanus.*

*American Ever-green Spindle-tree.*] Euonymus with a ſhrubby ſtem, dividing into many oppoſite branches, riſing ſix or eight feet high; garniſhed with ſpear-ſhaped ever-green leaves, growing oppoſite, and from the ſides and ends of the branches; ſmall cluſters of quinquifid whitiſh flowers, ſucceeded by roundiſh, rough, protuberant capſules, ſeldom ripening ſeeds in England.

*Variety.*] With variegated leaves.

Both theſe ſpecies and varieties are hardy, and ſucceed in any common ſoil and expoſure.

The firſt grows wild in hedges and woods in many parts of Britain, and other parts of Europe; but has been long an inhabitant of gardens, eſteemed for the ornamental appearance of its ſeeds, particularly the red ſorts, in October and November, when the capſules ſpread open, and expoſe the berry-like ſeeds, form a fine variety, the branches of which being uſed for making ſkewers and ſpindles, derives the name ſpindle-tree.

The ſecond is of American growth, and is a very pretty ever-green, for any ornamental plantation.

*Propagation of both Species.*

The *Euonymus Europæus*, and varieties, may be propagated plentifully by ſeeds, layers, and cuttings.

By Seed—Sow it in a bed or border of common earth, in October or November, covering with earth near an inch deep, and the plants will riſe in ſpring following, though ſometimes many of them not till the ſecond ſpring; keep them clear of weeds till autumn, then tranſplant them in nurſery-rows, and in two or three years they will be of due ſize for the ſhrubbery.

By Layers—Lay down the young ſhoots in autumn, or winter, or early in ſpring, giving them a ſlit at a joint, and they will be rooted by autumn following.

By Cuttings—In autumn take off cuttings of the young ſhoots eight or ten inches long, plant them in a ſhady border, and they will be rooted in one year.

Either of the two latter methods, or budding, or grafting, are the only certain way of continuing the varieties, which vary from one to the other by ſeed.

The ſecond ſort, and variety, is propagated chiefly by layers of the young branches in autumn, giving each a ſlit, and they will be rooted and fit to tranſplant by that time twelvemonth.

EUPATORIUM, Hemp Agrimony.

Of this genus, are ſeveral herbaceous flowery perennials for the pleaſure-ground, producing annual ſtalks from two to four or five feet high, adorned chiefly with ſimple leaves, and terminated by cluſters of compound flowers.

Claſs and order, *Syngeneſia Polygamia Æqualis.*

*Characters.*] CALIX, a ſcaly, imbricated general cup. COROLLA, ſeveral funnel-ſhaped hermaphrodite florets, five-parted, and ſpreading at the brim. STAMINA, five filaments, and cylindric antheræ. PISTILLUM, a ſmall germen, long bifid ſtyle, and narrow ſtigma. PERICARPIUM, none. SEMEN, an oblong downy ſeed under each floret.

[1]EUPATORIUM *Cannabinum.*

*Common European Hemp Agrimony*] Eupatorium with upright reddiſh ſtalks, three feet high, fingered-leaves, having oblong indented lobes, and the ſtalks terminated by large cluſter of pale red flowers.

[2]EUPATORIUM *Maculatum.*

*Spotted-ſtalked American Eupatorium.*] Eupatorium with upright dark purple-ſpotted ſtalks two feet high, garniſhed with ſpear-ſhaped, equally ſerrated, rough leaves by fives, and the top terminated by a corymbus cluſter of purpliſh flowers.

[3]EUPATORIUM *Aromaticum.*

*Aromatic White Penſylvanian Eupatorium.*] Eupatorium with upright ſtalks three feet high, oval obtuſe, trinervous, ſerrated leaves, and the ſtalks terminated by corymbus cluſters of white flowers.

[4]EUPATORIUM *Purpureum.*

*Purple-ſtalked Canada Eupatorium.*] Eupatorium with upright ſtalks four feet high, garniſhed with long, ſpear-ſhaped, unequally ſerrated, rough leaves by fours, and terminated at top by cluſters of purple flowers.

[5]EUPATORIUM *Altiſſimum.*

*Tall, long-leaved Penſylvanian Eupatorium.*] Eupatorium with upright ligneous ſtalks, four or five feet high, garniſhed with very long, ſpear-ſhaped, nervous, ſlightly ſawed leaves, and terminated at top by corymbus cluſters of white flowers.

[6]EUPATORIUM *perfoliatum.*

*Perfoliate Virginia Eupatorium.*] Eupatorium with upright ſtalks three feet high, garniſhed

niſhed with long rough leaves, connected at their baſe and perforated by the ſtalk, which is terminated by cluſters of white flowers.

All theſe plants have perennial roots, and annual ſtalks riſing in ſpring, flower in July and Auguſt, and produce ripe ſeed in autumn; the firſt grows wild in England, by water-ſides, but all the others are of American growth, and they are very hardy.

They are proper furniture for the compartments of large pleaſure-grounds, to encreaſe the variety of flowery perennials, and will ſucceed any where, but delight moſt in moiſt ſhady places.

Their propagation is by ſeed, and by parting the roots in autumn or ſpring.

Sow the ſeed on a bed or border of common earth, either on the ſurface and raked in, or in ſhallow drills half an inch deep; and when the plants are two or three inches high, prick ſome of them out five or ſix inches apart, to ſtand till autumn, then tranſplant them where they are to remain.

By parting the roots.—The roots furniſh off-ſets plentifully, which may be ſeparated in autumn, and planted out ſeparately, either into nurſery-beds for a ſeaſon, or at once in the places where they are to ſtand.

Their principal culture is, the keeping clean from weeds, digging about them annually, and cutting down the decayed ſtalks in autumn.

EUPHORBIA, burning thorny plant, including alſo *Tithymalus* (*Euphorbia.*)

This genus compriſes many ſhrubby and herbaceous ſucculents, moſtly tender exotics, for the ſtove and green-houſe; conſiſting chiefly of thick, fleſhy, ſucculent ſtalks and branches, frequently armed with thorns, obtaining in ſtature ſome ten or twelve feet, others ſcarce ſo many inches, of various ſingular growths, often entirely devoid of leaves, and with quadripetalous cloſe-fitting flowers.

Claſs and order, *Dodecandria Trigynia.*

*Characters.*] CALIX is monophyllous ventricoſe, four or five-parted, and perſiſtent. COROLLA, four or five thick truncated petals. STAMINA, twelve or more filaments, and globular didymous antheræ. PISTILLUM, a roundiſh trigonous germen, three ſtyles, and obtuſe ſtigmas. PERICARPIUM, a roundiſh trilocular capſule, and three roundiſh ſeeds.

The ſpecies chiefly cultivated in the Engliſh gardens, are.

[1]EUPHORBIA *Antiquorum.*

*Euphorbia of the Ancients.*] Euphorbia, with an upright, triangular, ſucculent, perennial ſtalk, riſing ſix or eight feet high, armed with crooked ſpines, and emitting on every ſide, many triangular irregular ſpreading branches, having at their extremities roundiſh leaves, that ſoon drop off, and ſometimes a few whitiſh flowers.

*Variety.*] With upright, three and four-angled, jointed, very thorny ſtalks, and erect branches.—(*Trigonum.*)

[2]EUPHORBIA *Neriifolia.*

*Oleander-leaſed Euphorbia.*] Euphorbia, with an upright, ſtrong, ſucculent, angular ſtalk, ſet with oblique tubercles, branches out near the top, and grows five or ſix feet high; the branches armed with crooked ſpines, and garniſhed with roundiſh deciduous leaves, ſucceeded by greeniſh white cloſe ſitting flowers.

[3]EUPHORBIA *Canarienſis.*

*Canary leafleſs Euphorbia.*] Euphorbia with an upright, four or five-angled, ſucculent, perennial, green ſtalk, branching out ſtrongly all around, armed with ſpines by pairs, and all the branches turning upward towards their extremities, no leaves, but ſmall whitiſh flowers at the ends of the branches.

[4]EUPHORBIA *Officinarum.*

*Officinal Euphorbia.*] Euphorbia, with ſeveral many angled, ſucculent, perennial ſtalks from the bottom, emitting irregular horizontal branches, gradually turning upward, armed with ſpines, and from the upper parts, greeniſh white flowers.

[5]EUPHORBIA *Tithymaloides.*

*Tithymaloides, or Myrtle-leaſed Baſtard Spurge.*] Euphorbia with ſhrubby, ſlender, ſucculent ſtalks and branches; riſing eight or ten feet high, oval acute-pointed leaves, ranged alternately on two ſides of the branches, and from the end of the branches ſeveral ſcarlet flowers.

*Variety.*] Laurel-leafed baſtard ſpurge—and with variegated leaves.

[6]EUPHORBIA *Caput Meduſæ.*

*Caput Meduſæ, or Meduſa's Head Euphorbia.*] Euphorbia with thick, roundiſh, ſucculent, ſcaly ſtalks, roundiſh ſcaly branches, twiſting over one another, appearing like many-headed ſerpents, narrow, thick, ſucculent leaves, and from the upper parts of the branches, white, cloſe-ſitting flowers.

*Varieties.*] Little Meduſa's head, having a ſhort ſtalk, ſix or eight inches high, and ſlender trailing branches, twiſting over one another—dwarf-trailing Meduſa's head, with ſwelling ſcales—low ſpreading Meduſa's head, without

without ſcales—deciduous, low ſpreading Meduſa's head, with leaves falling ſoon off—double branching, low, ſpreading Meduſa's heads.

All theſe ſpecies of Euphorbia, are very ſucculent in ſtalks and branches, abounding with a milky juice, ſo extremely acrid, as to burn linen, or bliſter the hand or any part of the ſkin, where applied; and the branches being ſo ſucculent, cuttings thereof, if preſerved dry, may be kept out of the ground ſeveral months if neceſſary, and then planted, will readily emit roots and grow.

They are all natives of the hot parts of Africa, Aſia, and America, and retained here in our ſtoves, as plants of curioſity, for the great ſingularity of their ſtrange growth.

In their culture here, they muſt be kept always in pots of very light, ſandy, or rubbiſhy poor ſoil, and placed upon the ſhelves in the hot-houſe.

They are all eaſily propagated by cuttings of their branches any time in ſummer; take off the cuttings with a knife, from three to five or ſix inches long; lay them on a dry ſhelf till the wound is dried up and ſkinned over, as for other ſucculent cuttings; when this is effected, plant them ſingly in ſmall pots of dry ſandy ſoil, and plunge them in the bark-bed, give a little water once or twice a week, and they will ſoon be well rooted, and may then be placed upon the ſhelves in any part of the ſtove.

They muſt be allowed larger pots occaſionally, once every year or two, but never put them in any too large; waterings will be neceſſary now and then, which in winter once a week is ſufficient, and not oftener than twice in ſpring and autumn, and about two or three times a week in the heat of ſummer.

---

# F.

FAGUS, the Beech-tree, and the *Caſtanea*, or cheſtnut tree.

This genus retains three hardy deciduous trees, two of them of large and beautiful growth, valuable to cultivate for timber, and for ornamental plantations; the other is a dwarf ſhrub-like tree for the ſhrubbery, all of them adorned with beautiful ſimple foliage, and monoecious amentaceous flowers.

Claſs and order, *Monoecia Polyandria.*

*Characters.*] Male and female flowers on the ſame tree, collected into globular and cylindric amentums, having monophyllous cups, five-parted in the males, and four in the females. COROLLA none. STAMINA, many filaments in each cup, and oblong antheræ. PISTILLUM, a germen, three ſtyles and ſimple ſtigmas. PERICARPIUM, a large roundiſh ſpinous capſule, formed of the calix, containing two nuts.

The ſpecies are;

[1]FAGUS *Sylvaticus.*

*The Beech tree.*] Fagus, with an upright, ſtraight, ſmooth trunk, riſing ſixty or ſeventy feet high, and of proportionable bulk, branching upward, into a fine regular head, garniſhed with oval, ſerrated leaves; flowers in globular katkins, ſucceeded by angular fruit called maſt.

*Varieties.*] With yellow ſtriped leaves—white ſtriped leaves—with purpliſh leaves.

[2]FAGUS *Caſtanea.*

*Caſtanea or Cheſtnut-tree.*] Fagus, with an upright large trunk, growing forty or fifty feet high, branching regularly around, into a fine ſpreading head, garniſhed with large, ſpear-ſhaped, acutely ſerrated leaves, naked on the under ſide, flowers in long amentums, ſucceeded by round prickly fruit, containing two or more nuts.

*Variety.*] Gold ſtriped-leafed-cheſtnut-tree.

FAGUS *Pumila.*

*Dwarf Cheſtnut-tree, or Chinquepin.*] Fagus with a ſhrub-like ſtem, branching eight or ten feet high, oval, ſpear-ſhaped, acutely ſerrated leaves, hoary on the under ſide.

The flowers of all theſe trees are very inconſiderable in appearance, thoſe of the beech-tree are collected into roundiſh heads appearing in May and June, ſucceeded by the maſt, an angular

angular fruit, in autumn; and the flowers of the two ſpecies of cheſtnuts are gathered into long katkins, appearing in May, ſucceeded by the nuts in autumn, in large, round, prickly covers, each containing one, two, or more nuts.

The firſt two ſpecies may be ranked with the firſt claſs of timber trees, both for their ornamental appearance when growing, and their various uſes when felled as timber; no trees are more ſuitable for parks, extenſive lawns, large wilderneſs works and clumps, or on the ſides of woods, fields, avenues, and by the ſides of large ridings; that beſides their ornamental appearance when growing, and expectation of their valuable timber, they afford a plentiful annual crop of fruit for ſwine, deer, and other animals, and the fruit of the cheſtnut tree is often eaten at table, and is greatly eſteemed by many when roaſted; the fruit do not however, always arrive at ſuch perfection here as in Spain, from whence great quantities are annually ſent hither in winter.

The beech was formerly much employed to form hedges, to ſurround the quarters of the pleaſure-grounds, according to the ancient mode of dividing the ground into regular ſquares, angles, &c. it forms a very handſome hedge, when neatly ſheared twice every ſummer, i. e. about Midſummer, and again in Auguſt.

The timber of thoſe trees are va'uable for many purpoſes; that of the beech is eſteemed by the turners, as alſo by joiners, for making bedſteads, chairs, ſtools, dreſſer-boards, coffins, &c. and as to the cheſnut, the uſes of its timber are almoſt univerſal, not only for building, but for many other ſtrong purpoſes, as well as for making fine tables, chairs, bedſteads, &c. and all ſorts of veſſels to hold liquor; as under-wood, it is alſo ſuperior for poles for hops, and various other uſes.

As to the dwarf cheſtnut, it is only employed for variety in ſhrubberies, and other ornamental plantations.

All the ſorts will thrive on almoſt all ſoils and ſituations, in ſandy, gravelly, loamy, or clayey land, either on plains, declivities, or ſides or tops of hills.

*Propagation and Culture.*

Firſt of the beech tree. This is eaſily raiſed from the maſt or ſeed, which ripens abundantly in September, and which may either be ſown then, or in a month or two after, or towards ſpring; for which prepare beds four feet wide, and raking the earth evenly from off the ſurface, about an inch deep, then ſow the maſt, and beat it gently down with the back of the ſpade, and cover it over with the earth the above depth; in ſpring many plants will come up, others not till a year after, and when they are two years old, plant them out in nurſery rows, two feet and half aſunder, to remain till they are four or five feet high, or more, and then tranſplant them, where they are to remain.

Second, the cheſtnut tree. This tree is alſo propagated by ſeeds, i. e. the nuts, which ſometimes ripen perfectly in England, but in default of this, there are vaſt quantities imported annually from Spain and Portugal, which are rather preferable, either of which are to be preſerved in ſand till February, then ſow them in drills; let the drills be made a foot aſunder, and near three inches deep, in which place the nuts two or three inches diſtance, and earth them over, they will ſoon germinate, and come up freely the ſame ſpring; all the culture they require, is to be occaſionally hand-weeded, and when two years old, tranſplant them in February in the nurſery rows, at which time, previous to planting, ſhorten their roots and trim off all ſide-ſhoots, then plant them in lines two feet and half diſtance, and half that diſtance in the rows; and after having four or five years growth, they will be of due ſize to plant out for good, either for ornamental plantation, or as foreſt trees.

If a wood or plantation of theſe trees are deſigned for profit, they may be planted any where not too wet, placing them ſix feet diſtance, which is ſufficient room to grow for poles, when they may be cut down within a foot of the ground, leaving a ſufficiency of the moſt promiſing at twenty feet diſtance, to grow up for timber.

The dwarf-cheſtnut, or chinquepin, is alſo raiſed from the nuts, which are procured from America by the ſeedſmen, and are to be planted in drills, and in every reſpect as the common ſort.

The variegated-leafed kinds are continued by budding, grafting, or inarching in ſtocks of the common ſorts.

FEMINEUS *flos*, a Female Flower.

A Female Flower, according to the ſexual ſyſtem, is that which is furniſhed only with the *piſtillum*, or female organs of generation, i. e. the germen, ſtyle, and ſtigma, but wants the ſtamina, or male organs altogether.

They

They, the Female Flowers, are produced apart from the males either on the ſame plant, as in cucumber, melon, gourd, mulberry, and other plants of the claſs *monoecia*; or on diſtinct plants, as in all the genera in the claſs *dioecia*. See CLASSIS.

FEMINA *planta*, a Female Plant, a plant which produces female flowers only, as ſpinach, hemp, poplar, juniper, *meniſpermum*, *myrica*, and other genera of the claſs *dioecia*.

FERULA, Fennel-giant.

The plants are large, herbaceous, flowery perennials, producing annual ſtalks eight or ten feet high, terminated by yellow umbels of flowers.

Claſs and order, *Pentandria Digynia*.

*Characters*.] CALIX, umbellate flowers, having a caduous general involucrum, and a many-leaſed partial one, and ſcarce any calix to the florets. COROLLA, a globular general umbel, compoſe of many quinquepetalous florets. STAMINA, five filaments and ſingle antheræ. PISTILLUM, a turbinated germen, two ſtyles, and obtuſe ſtigma. PERICARPIUM, an elliptical, plane, two-parted fruit, and two ſeeds.

The principal ſpecies are:

[1]FERULA *Communis*.

*Common Fennel-giant*.] Ferula, with long thick, juicy roots, crowned by very long many-parted leaves, compoſed of numerous very long, narrow, undivided ſegments, ſpreading widely on the ground, upright, ſtrong, jointed, hollow ſtalks, ten or twelve feet high, garniſhed with divided leaves, and terminated by roundiſh umbels of yellow flowers.

[2]FERULA *Ferulago*.

*Ferulago, or Pinnatifid Galbanum Fennel-giant*.] Ferula with long, thick, juicy roots, crowned by long pinnatifid leaves, of numerous plane three-parted ſegments, ſpreading widely on the ground; upright, ſtrong, jointed, hollow ſtalks, ſeven or eight feet high, terminated by roundiſh umbels of yellow flowers.

Of the juice of the roots of them is prepared the drug *galbanum*.

[3]FERULA *Tangitana*.

*Tangier ſhining Ferula*.] Ferula, with very thick juicy roots, crowned by many-parted, ſhining leaves, compoſed of numerous jagged unequally three-parted ſegments, ſpreading widely on the ground; upright, ſtrong, hollow, ſtalks, eight or ten feet high, terminated by large umbels of yellow flowers.

[4]FERULA *Glauca*.

*Glaucous Fennel-giant*.] Ferula with a thick juicy root, crowned by large many-parted glaucous, or grey leaves, of many narrow plane ſegments, upright, ſtrong, jointed, hollow ſtalks, ſix or eight feet high, terminated by yellow umbels.

All theſe ſpecies of *Ferula* have thick, fleſhy, perennial roots, ſpreading and penetrating deep into the ground, leaves ſpreading widely around; and ſtalks an inch and half thick, are perennial in root, but annual in leaf and ſtalk, which riſe in ſpring, flower in June and July, ripen ſeeds in September, and decay ſoon after.

They are proper furniture for the large compartments of extenſive pleaſure-grounds, they will grow any where, but grow talleſt and ſtrongeſt in deep ſoils.

Their propagation is effected by ſeed, in autumn or ſpring, in drills twelve inches aſunder, ſowing it thinly, and cover it near an inch deep, and when the plants are a year old, tranſplant the largeſt into the places where they are to remain.

FICUS, the Fig-tree.

The common fig-tree of our gardens conſiſts only of one ſpecies, very comprehenſive in the varieties of its fruit, is of the deciduous tribe, moderately hardy, producing fruit in great perfection againſt walls, alſo tolerably in eſpaliers and ſtandards; but beſides this ſort, there are ſeveral other tender exotic ſpecies, ſometimes retained in our hot-houſes, for variety; we ſhall however firſt exhibit the culture of the common kind.

Claſs and order, *Polygamia Trioecia*.

*Characters*.] CALIX androgynous, male, and female flowers upon three diſtinct plants, included in great numbers within the fruit, which ſerve as a general calix, or receptacle, each floret having, in the males a three, and the females a five-parted cup. COROLLA, no petals to the florets. STAMINA, three briſtly filaments in the males, and didymous antheræ. PISTILLUM, in the females, an oval germen, reflexed ſtyle, and two reflexed ſtigmas. PERICARPIUM, none, but the numerous ſeeds are lodged in the general calix, and which become the fruit.

The fruit of the fig-tree, in the vulgar acceptation of the word, is the common calix, to the flowers, which are numerous very ſmall florets, that line its internal ſurface, ſo that

that they are not viſible without opening the fruit or common receptacle.

Theſe flowers are in ſome trees female only, in others male, and ſome male and female within the ſame receptacle.

The ſpecies of the common fig-tree is;

FICUS *Carica.*

*Common cultivated Fig-tree.*] Ficus, with an upright ſtem, branching fifteen or twenty feet high, garniſhed with large palmated or hand-ſhaped leaves.

The leaves are generally more or leſs divided into five principal parts.

This tree always produces its fruit upon the young ſhoots of the former year, riſing immediately from the eyes of the ſhoots, appearing firſt like ſmall buds, which encreaſe gradually in ſize till July, Auguſt, and September, when they arrive at full growth, are large, ſomewhat pear-ſhaped, and as it approaches to ripeneſs, the ſkin changes gradually from a greeniſh to blueiſh, purpliſh, blackiſh, whitiſh, or yellow colours in different varieties, full of a purpliſh, reddiſh, whitiſh, or yellow pulp, becomes very ſoft, juicy, and extremely rich and luſcious.

The principal *Varieties* of this fruit are:

*Common Fig.*—A large oblongiſh, dark, purple-blue fruit; the tree a great bearer, and ripens in great perfection in Auguſt, either on ſtandards or walls.

*Brown or Cheſtnut Fig.*—A large globular, ſhortiſh, cheſtnut-coloured fruit, having a purpliſh delicious pulp, ripen in July and in Auguſt.

*Black Iſchia Fig.*—A middle-ſized, ſhortiſh, flat-crowned, blackiſh fruit, having bright pulp; ripe middle of Auguſt.

*Green Iſchia Fig.*—A large oblong, globular-headed greeniſh fruit, ſlightly ſtained through by the pulp to a reddiſh brown colour; ripe end of Auguſt.

*Brown Iſchia Fig.*—A ſmall pyramidal, browniſh, yellow fruit, having a purpliſh very rich pulp; ripe in Auguſt and September.

*Malta Fig.*—A ſmall flat-top'd brown fruit; ripe the middle of Auguſt and September.

*Round Brown Naples Fig.*—A globular, middle ſize, light brown fruit, and browniſh pulp; ripe end of Auguſt.

*Long Brown Naples Fig.*—A long dark-brown fruit, having a reddiſh pulp; ripe in September.

*Great Blue Fig.*—A largiſh blue fruit, having a fine red pulp.

*Black Genoa Fig.*—A large pear-ſhaped black-coloured fruit, and bright red pulp; ripe in Auguſt.

*Divided-leafed Fig-tree,*—having the leaves deeply divided into many narrow ſegments, valuable principally for the ſhrubbery for the variety of its leaves.

There are many other varieties, but it is unneceſſary to recount them, ſome of them being nearly alike, and many of them will not ripen perfectly in our gardens.

Moſt of the above varieties of figs will bear plentifully againſt walls of a ſouth, eaſt, or weſt aſpects, and will alſo bear very well in eſpaliers; they will likewiſe in fine dry ſummers, produce tolerable good crops on ſtandards, in a full expoſure, either as full ſtandards, half ſtandards, or dwarfs, and ſometimes produce greater crops of fruit than thoſe trained againſt walls.

Having remarked above, that in fig-trees, it is the year-old ſhoots only that produce the fruit, this however is often formed upon the ſhoots the preceding ſummer, appearing in autumn like very ſmall buds, as aforeſaid, at the places of the leaves; many alſo come out in ſpring, from which we are principally to expect our beſt crops: let it alſo be remarked, that in autumn after the main crop of ripe fruit is gone, you will generally ſee many green fruit remaining, quarter or half grown, theſe are ſuch that are produced early upon the ſame ſummer's ſhoots, which in warm countries arrive alſo to perfection the ſame ſeaſon; ſo that they have two crops annually, but theſe rarely ever attain perfection in England, unleſs aſſiſted by hot walls, nor will they ſtand the winter to come to perfection the ſucceeding year, therefore all theſe ſorts ſhould be pulled off at the fall of the leaf in autumn.

Fig-trees are the moſt uncertain of any in producing good crops of fruit in England, their young ſhoots and fruit being both very liable to ſuffer by froſt; for in ſome ſeaſons the young ſhoots do not ripen or harden, but remain ſoft, pithy, and full of juice, and the winter froſts often kill their upper parts, in which caſe but little fruit can be expected the ſucceeding ſummer, as the fruit is always principally produced towards the extremities of the ſhoots; therefore, to preſerve the ſhoots in ſevere winters, ſome of the choiceſt ſorts againſt walls, may be matted during the inclemency of the weather.

It is the robuſt, ſhort-jointed ſhoots that are the principal bearers; the long, ſtraight,

ſmooth ſhoots, ſeldom bear much; the former ſorts ſhould therefore be chiefly retained for bearing. See their *Culture*.

All the varieties of theſe trees proſper in any common ſoil of a garden, prepared by common digging, or trenching one or two ſpades deep.

They may be planted at fifteen or twenty feet diſtance, againſt walls and eſpaliers; and as ſtandards, any diſtance not leſs than fifteen feet from one another.

*Propagation.*

The propagation of fig-trees is effected with great eaſe three different ways, viz. by ſuckers ariſing from the root, by layers, and by cuttings.

By Suckers.—The trees commonly ſend up many ſuckers annually in ſummer, which, in autumn following, may be tranſplanted: in taking them off, go as low as poſſible to the old root; trim off any ragged part at bottom, leaving their tops intire, eſpecially if for ſtandards, and plant them in nurſery lines, two or three feet diſtance, or may be planted at once, where you deſign they ſhall remain to produce their fruit; obſerving, if they are deſigned for dwarfs, for walls, or eſpaliers, they, if long may be headed to ſix or eight inches in March, the more effectually to force out lateral ſhoots near the bottom, as obſerved of eſpalier and wall trees; but if intended for ſtandards, they muſt not be topped, but trained with a ſtem, not leſs than fifteen or eighteen inches for dwarf-ſtandards, a yard for half-ſtandards, and four, five, or ſix feet for full ſtandards, and then muſt be ſuffered to branch out to form a head, obſerving, that whether againſt walls, eſpaliers, or ſtandards, the branches or ſhoots muſt never be ſhortened, unleſs to procure a neceſſary ſupply of wood, for the fruit being always produced upon the upper parts of the young ſhoots, that if cut off, no fruit can be expected.

By Layers.—Autumn is the beſt ſeaſon, though it may be done any time from October till March or April. Chuſe the young pliable lower ſhoots from the fruitful branches, lay them in the uſual way, covering the body of the layers three or four inches deep in the ground, keeping the top entire, and as upright as poſſible, and they will be rooted, and fit to ſeparate from the parent in autumn, then plant them either in the nurſery, or where they are finally to remain, managing them as ordered above for the ſuckers.

By Cuttings.—Autumn, at the fall of the leaf, or any time in March, is the time to plant them: chuſe well ripened ſhoots of the preceding ſummer, ſhort, and of robuſt growth, from about twelve to fifteen inches long, having an inch or two of the two-years wood at their baſe, the tops left entire, and plant them ſix or eight inches deep, in a bed or border of good earth, in rows two feet aſunder: and when planted in autumn, it will be eligible to protect their tops in time of hard froſt, the firſt winter, with any kind of long looſe litter, managing them afterwards as the ſuckers.

*Culture as wall and eſpalier trees.*

Conſidered as wall and eſpalier trees, they ſhould be allowed a ſunny ſituation, being neceſſary to forward the ripening of the fruit, and promote a rich flavour: they ripen earlieſt in a full ſouth expoſure, but they will alſo ſucceed very well in an eaſt and weſt aſpect; and as to diſtance, fifteen or twenty feet is neceſſary; againſt a high wall the former diſtance is ſufficient, but if they are rather low, twenty feet ſhould be allowed.

With reſpect to training, that having headed down the firſt ſhoots, to procure bottom branches, as for other wall and eſpalier trees, the branches muſt be laid in a ſomewhat horizontal poſition, preſerving an equal number on both ſides of the tree, ranging to the right and left, at eight or ten inches diſtance, one above another; for the leaves being large, the branches ſhould be laid wide accordingly, training each alſo at full length, for reaſons before laid down, unleſs there is an immediate want of wood; a ſupply of branches, either to give the tree its firſt due formation for the wall or eſpalier, or as a farther ſupply to furniſh the wall, &c. in which caſes, ſome convenient ſhoots contiguous may be ſhortened to five, ſix, or eight inches, to force out laterals for the neceſſary ſupply; though theſe trees for the general part, naturally furniſh wood enough to render the work of ſhortening unneceſſary.

For, as I before obſerved, theſe trees always producing their fruit upon the upper parts of the young wood, the branches ſhould conſequently, in the general courſe of culture, be always trained at full length, as ſhortening would cut away the only bearing parts, and force out innumerable unneceſſary ſhoots; and it will be found, that the trees ſeldom fail to furniſh a natural ſupply of ſucceſſive young wood annually for each year's bearing; obſerve likewiſe, that in conſequence of the

trees

trees bearing fruit upon the year-old wood only, particular attention is requiſite to preſerve an annual ſupply of each ſummer's ſhoots in every part of the tree, not only one at the extremity of every branch, but likewiſe occaſionally in the lower parts, quite from the bottom, coming up in ſucceſſive order, one after another, at proper intervals, between all the principal branches; that every part of the wall or eſpalier may be occupied with bearing wood; and, as the lower young branches advance upward, the old naked ones that ſupport ſcarce any young wood, or ſuch that are too high for the wall, muſt be cut away either to their origin, or to ſome convenient young lower branch or ſhoot that they may ſupport, training that up to ſupply the place of the part cut out. By obſerving as above, you will be able to have every part of your wall and eſpalier tree full of fruitful wood, quite from the bottom to top, and ſide extremities.

With reſpect to pruning, two principal dreſſings is requiſite annually, to thoſe againſt walls, &c. that is, a ſummer and winter pruning and training.

Summer Dreſſing.—The trees commonly produce great numbers of young ſhoots every ſummer, frequently many more than are neceſſary; ſome of the moſt irregular and ill-placed ſhould be taken off, and the reſt trained in cloſe and at full length for next year's bearing, that by this regulation the ſun and air may be more effectually admitted, to promote the free growth and regular ripening of the fruit, the main object. June, July, and Auguſt for this work of ſummer dreſſing, obſerving, that in performing the operation, I would adviſe to take off only ſuch ſhoots that are very irregular, and ſuch others that cannot be poſſibly trained in; for in theſe trees, it is proper to retain in ſummer, when practicable, three times more than may ſeem neceſſary for the winter or ſpring training, becauſe the ſhoots being rather of a ſucculent, pithy nature, many of them are often killed in winter, ſo that by reſerving them all till the general pruning in ſpring, there may be a ſufficiency eſcape to chuſe from, to furniſh the tree, and if more than neceſſary, they are eaſily cut out, therefore in this dreſſing, take off principally only the foreright and other very irregular, and evidently uſeleſs ſhoots, rubbing or cutting them off quite cloſe; let the others be trained to the wall or eſpalier, between the main branches at full length, ſtill continuing them ſo, as they advance.

Obſerve however in the ſummer dreſſing, that if there is any great want of wood in any part, you may in June pinch or top any contiguous young ſhoots, whereby it will furniſh a ſupply of collaterals the ſame ſeaſon, to ſupply the vacancies.

If the above operation of ſummer dreſſing is begun early, before the ſhoots become woody, the redundant young wood may be rubbed off without employing a knife.

Winter or general Pruning.—Having obſerved above, that many of the young branches of Fig-trees are liable to be more or leſs damaged in ſevere winters, in conſequence thereof, it is adviſable to defer this general pruning till ſpring, reſerving till then all the ſhoots retained in the ſummer dreſſing, and out of the whole, enough may eſcape the froſt for our purpoſe, and if more than enough, the better, there will be the more to chuſe from; but if the general pruning was performed in autumn, or early in winter, and no more ſhoots left than what is juſt neceſſary to furniſh the wall or eſpalier, and many of theſe ſhould be deſtroyed by the inclemency of the weather, there is no reſerve left to ſupply the deficiencies; I would therefore adviſe the general pruning to be deferred till February or March.

This work of winter pruning, conſiſts of regulating the branches in general, old and young, taking out crowding and naked old branches, thining and ſelecting the proper ſupply of young ſhoots, cutting out all weak and ill ripened ones, and all dead wood.

With reſpect to the regulation of the principal branches, theſe ſhould be about eight or ten inches diſtance, that where they have been trained conſiderably cloſer, they ſhould now be thinned, and the contiguous ones all unnailed, that the whole may be trained regular at the proper diſtance, at the ſame time examine if there are any old naked branches, i. e. ſuch; that have advanced a conſiderable length, without furniſhing hardly any proper bearing ſhoots, or young branches furniſhed with ſuch and that, provided there is proper young wood favourably ſituated to ſupply their place; ſuch old naked branches ſhould be occaſionally cut out at this pruning, to the place from whence they proceed, or at leaſt down to the firſt beſt young ſhoot or branch, cutting them quite cloſe, never leaving any ſtump, ſo train the proper branches and ſhoots in its ſtead; having particular attention that every branch terminates in a young ſhoot, either ariſing immediately from its extremity,

or in default thereof, or that the end of the extreme ſhoot is dead, or that the branch is too long for its allotted ſpace, it may be ſhortened to the next firſt, ſecond, or third good ſhoots below, if any, as ſhall ſeem convenient, leaving each ſhoot at full length, unleſs its end is dead, when it muſt conſequently be cut down to the live wood.

From the principal branches paſs to the ſupply of young wood, produced and trained in the preceding ſummer, which, if they have eſcaped the froſt, there will be probably many more than is neceſſary now to be retained; and keeping in view, as we formerly hinted, that they are the only bearers, and a proper ſupply muſt be trained now for next ſummer's fruit: every branch muſt not only terminate in one at full length, by the rules elucidated above, but collateral ones ſhould alſo be here and there retained, ſome towards the bottom of the branches, others nearer the middle, and ſome more towards the extreme parts, &c. advancing at proper diſtance one after another, as it were in ſucceſſive order, between the principal branches; and that beſides the ſupply of fruit they will thus furniſh in every part, you will alſo have your wall or eſpalier ſo regularly filled with advancing young branches, that as old branches become naked, or two extenſive for the ſpace of walling or eſpalier allotted, as may be the caſe in ſome part or other of the tree every ſeaſon, there is always a reſource of theſe young branches coming up gradually to ſucceed them; therefore at every general winter or ſpring pruning, ſelect in the different parts of the tree, as above, a proper ſupply of the beſt ſhoots, ſuch as are robuſt, and their buds near together, and ariſe from the upper or under ſides of the branches convenient for training in, at the ſame time cutting off all long foreright and other ill-placed ones, and all others however good, that are redundant or ſuperfluous, cutting every thing quite cloſe to the ſurface of the branches, leaving all the ſelected ſhoots at full length, where practicable, for the reaſons already aſſigned; never ſhortening any only in caſe of dead parts, or want of an immediate further ſupply of ſhoots in any part to fill a vacancy.

Having therefore finiſhed this general pruning, let all the branches and ſhoots be faſtened in regular order to the wall or eſpalier, each at full length, and as ſtraight as poſſible, preſerving all the main branches eight or ten inches diſtance.

*Their Culture as Standard Trees.*

Standard Fig-trees, whether dwarfs or half or full ſtandards, after being trained to their proper form, as already directed in the article of propagation, may be planted either in the borders or open quarters of the kitchen garden, or in the pleaſure-ground, detached from other trees, and not nearer than fifteen or twenty feet to each other.

As to culture, they, in ſtandards require very little training or pruning, all that is neceſſary, is only taking out any very irregular branch, or when their general branches are too much crouded, to thin them diſcretionally, taking out the worſt and moſt irregular growing; obſerving alſo the ſame of the young ſhoots, where they are greatly crowded, thin out ſome of the ill-placed ones, and ſuch as are weak and ill-ripened, obſerving, that the ſhoots and branches are always to be left entire, except in caſes exhibited in the wall and eſpalier culture, as that of cutting off the dead ends of ſhoots, &c. and thus they will often bear plentifully, and ripen their fruit frequently in as great perfection as againſt walls.

*The Tender Species of Ficus.*

FICUS, &c. The following tender ſpecies of *Ficus* are preſerved in ſome of our hot-houſes, viz. by way of curioſity.

[1]FICUS *religioſa.*

*Sacred Fig, or Indian God-tree.*] Ficus with a woody ſtem, branching twenty or thirty feet high, heart-ſhaped entire leaves, ending in long acute points.

This is held in great veneration in India, where it is called the religious tree.

[2]FICUS *Sycomorus.*

*Sycamore and Mulberry-leaved Egyptian Fig-tree.*] Ficus with a robuſt ſtem, branching twenty or thirty feet high, and large, roundiſh, heart-ſhaped, entire leaves.

[3]FICUS *Benghalenſis.*

*Bengal Fig-tree.*] Ficus with ſeveral ſtems, dividing into many implicated branches, riſing twenty or thirty feet high, ſtriking root from their lower parts, and large, oval, obtuſe, entire leaves.

[4]FICUS *Indica.*

*Long-leaved Indian Fig-tree.*] Ficus with a robuſt ſtem, branching twenty or thirty feet high, and long, ſpear-ſhaped, entire leaves.

[5]FICUS *Pumila.*

*Dwarf Indian Fig.*] Ficus with trailing rooting ſtalks and branches, and oval, acute-pointed, entire leaves.

All

All theſe ſpecies are natives of hot countries, where moſt of them form large trees, but in our ſtoves appear as ſhrubs, and their fruit is of no value.

To preſerve them here they muſt be kept in pots and retained in the ſtove. Their propagation is by cuttings, in ſummer, planted in pots of light ſandy earth, and plunged in the bark-bed.

FILAMENTUM, Filaments, or thread-ſhaped parts of the ſtamina, which elevate the antheræ. See ANTHERÆ and STAMEN.

Filaments are in figure either ſlender like a hair, awl-ſhaped, wedge-ſhaped, or flat, ſometimes twiſted like a ſcrew, and ſometimes bent backwards, as in ſuperb lily, &c. and in many plants are covered with a fine cottony down; and as to proportion, Filaments in ſome plants are very long, in others very ſhort; of equal lengths, as in moſt flowers, or irregular and unequal, as in the lip and cruciform flowers, which two laſt circumſtances conſtitute the claſſes *Didynamia* and *Tetradynamia*. See CLASSIS.

The ſituation of the Filaments is, in flowers of one petal (*monopetala*), generally inſerted into the baſe of the corolla; in flowers that conſiſt of more than one petal, they are attached either to the calix, as in the claſs *icoſandria*; or to the receptacle, as in the claſs *polyandria*; but in ſome genera, the Filaments are neither inſerted into the calix, corolla, nor receptacle, but into the piſtil or ſtyle, as in all the genera of the claſs *gynandria*.

From the number of Filaments in flowers, is founded the firſt thirteen claſſes. See CLASSIS.

FLOS, the Flower, or parts of fructification of plants, &c.

A Flower is defined to be formed of all the parts of fructification neceſſary for the generation of all trees and plants, and conſiſts of the following principal parts.

The *Calix*, empalement or cup; the outer green leaves immediately ſurrounding the corolla or petals. See CALIX.

The *Corolla*, petals; or flower-leaves the fine-coloured leaves placed within the calix, and which immediately ſurround the ſtamina, &c. See COROLLA.

The *Stamina*, or male organs; the ſlender thread-ſhaped parts, ſupporting the antheræ, placed immediately within the corolla, and ſurround the piſtillum. See STAMEN.

The *Piſtillum*, or female organs; conſiſting of the germen, ſtyle, and ſtigma, and are placed within the antheræ, and commonly occupy the centre of the flower. See PISTILLUM.

The *Pericarpium*, the fruit or ſeed-veſſel, formed of the germen of the femal organ, and ſucceeds to maturity after all the other parts of the Flower are decayed. See PERICARPIUM.

The *Semen*, or ſeeds, lodged within the pericarpium, or in default thereof, in the bottom of the calix, &c. See SEMEN.

Each of the above parts of a flower is fully explained under its reſpective head, which ſee.

But as many Flowers have neither calix nor corolla, they are ſtill to be conſidered as a Flower, provided it is furniſhed with the *antheræ* or tops of the male organ, and the *ſtigma* or ſummit of the ſtyle, the female organ, for the eſſence of a Flower conſiſts in theſe two principal organs *antheræ* and *ſtigma*.

In many plants however we have not been able to diſcover any reſemblance of Flower or fruit, ſuch as the ferns, moſſes, muſhroom, &c. but it is probable they are all furniſhed with ſimilar parts, although their minuteneſs or concealed ſituation within the plant, prevents any diſcovery thereof.

FOLIOLA, Folioles, the leſſer Leaves or lobes of a compound Leaf.

FOLIUM, a leaf, or leaves, defined to be the organs of vegetation, and principal ornament of plants.

Leaves are ſuch uſeful and neceſſary organs, that they attract and tranſpire the air for the vegetable ſupport and life of the plants, as well as promote the growth of the flowers, fruits and ſeeds of every ſort. Trees periſh when totally diveſted of them at an improper ſeaſon, witneſs thoſe which have undergone the depredations of inſects and blights; likewiſe the practice of ſtripping off ſome leaves from plants, when we would ſuſpend their growth; and ſometimes in cold years, to admit the ſun to accelerate the ripening of choice wall fruit; but in this caſe, it ſhould not be practiſed till the fruit have acquired nearly their full bulk, and then only juſt thin out ſome where they too cloſely ſhade the fruit, for the leaves contribute greatly to their growth.

Far the greater number of plants are furniſhed with Leaves, though in ſome they are totally wanting, as in the *fungi* or muſhroom tribe, ſhrubby horſe-tail, and ſeveral kinds of fleſhy ſucculent plants.

All foliated plants and trees however, are not always adorned with Leaves, as for example, all the deciduous tribe are totally diveſted

veſted of them during the winter; but moſt ſorts both deciduous and ever-greens, produce new Leaves every year.

Leaves are of various figures, but generally extended into a plane membranaceous or ſkinny ſubſtance, and formed by the expanſions of the veſſels of the foot ſtalk, which divide into many ramifications or branches, croſſing each other, form a kind of net, the meſhes or interſtices, of which are filled up with a tender pulp or pith; this pulpy ſubſtance being ſometimes conſumed by certain inſects, whilſt the net-work remaining, exhibits the ſkeleton of the Leaf.

All leaves have one ſide very diſtinguiſhable from the other, an upper and under ſurface, the former turned towards heaven, the latter downward, and this diſpoſition is ſo eſſential to the vegetable oeconomy, that if a branch is overturned in ſuch a manner as to deſtroy the natural direction of the Leaves, they will, of themſelves, in about a week or little more or leſs time reſume their former poſition, and that as often as a branch is overturned; it is alſo obſervable, that from the time the Leaves are turned into a contrary direction, till they have recovered the natural poſition, the fruit makes hardly any progreſs in growth, which ſhews how neceſſary it is to preſerve all the branches of wall and eſpalier-trees firmly in their proper places, and when any is overturned by wind or other accidents, no time ſhould be loſt in faſtening them up again, before the Leaves take a wrong direction.

Leaves conſidered with reſpect to their form and diſpoſition, may be divided into three claſſes, Simple, Compound, and Determinate.

*Simple Leaves.*

Simple Leaves are ſuch as grow ſingly on a foot-ſtalk, or a foot-ſtalk terminated by a ſingle expanſion only, either entire or divided; that however deep the diviſions, if they do not reach the middle rib, it is ſtill a ſimple leaf; and as their different ſhapes, both entire and divided, are numerous, we will here exhibit the moſt material, each according to the botanic term or name.

*Aceroſum*, chaffy; ſuch as are very narrow and ever-green, as yew, pine, fir, and cedar.

*Acinaciforme*, ſcymitar-ſhaped; being fleſhy, ſpear-pointed, having one edge narrow and convex, the other broad, as in *Meſembryanthemum Acinaciforme*.

*Aculeatum*, aculeate or prickly; as in ſome of the thiſtles.

*Acutum*, acute; terminated by a ſharp point.

*Acuminatum*, acuminate; having the extremity ſharp, like the point of an awl.

*Anceps*, two-edged.

*Bullatum*, bullated; bliſtered, or ſtudded.

*Bifidum*, bifid; divided into two parts.

*Canaliculatum*, channelled or fluted.

*Carinatum*, carinate, or keel-ſhaped; as in keel-ſhaped *aloe*.

*Carnoſum*, carnoſe, or fleſhy.

*Cartilagineum*, cartilaginous; having a griſtly, thick, fleſhy edge, different from the other part of the Leaf.

*Ciliatum*, ciliated or eye-laſhed; having the edge ſurrounded longitudinally with parallel hairs.

*Cirrhoſum*, cirrhoſe; ending with cirrhi, tendrils, or claſpers.

*Coloratum*, coloured; as in *Amaranthus tricolor*.

*Compreſſum*, compreſſed; having a mark of impreſſion equally on both ſides.

*Concavum*, concave, hollow; the ſurface hollow in the middle, oppoſed to convex.

*Convexum*, convex; the middle riſing higher than the ſides.

*Cordatum*, *Cordiforme*, } cordated, cordiform, or heart-ſhaped, as in the lime-tree.

*Cordatum-obverſe*, obverſely cordated, or heart-ſhaped reverſe.

*Crenatum*, crenated or notched; having the border indented or notched, that the indentings turn neither towards the top nor baſe, and are termed

——— *acutum*, when acutely or ſharply crenated; having the indentures ſharp at the ends.

——— *obtuſum*, obtuſe or bluntly crenated; having the ends of the indentures rounded.

——— *duplicato*, doubly crenated; having ſmall notches on the larger crenatures.

*Criſpum*, criſped, curled; as in curled-mallow, curled-parſley, &c.

*Cuneiforme*, wedge-ſhaped; being much longer than broad, narrowing gradually from the top.

*Deltoide*, deltoid, quadrangled; having four angles, thoſe at the extremities more diſtant from the centre than thoſe of the ſides, as in *Meſembryanthemum deltoides*, and *atriplex Halamus*.

*Dentatum*, indented; toothed, or having the borders ending in horizontal points.

*Depreſſum*, depreſſed; having a mark of impreſſion on one ſide.

*Delabriforme*,

*Dolabriforme*, hatchet-ſhaped, is compreſſed, projecting outward with a ſharp edge.

*Emarginatum*, emarginated; notched at the top, and are termed

——— *acutum*, when acutely emarginated; having the parts on each ſide, ending in ſharp points.

——— *obtuſum*, obtuſely emarginated; having the two ſides ending in blunt points.

*Integerrimum*, entire; having the borders entire, or free from all intendings or notches.

*Enſiforme*, ſword-ſhaped; being compreſſed and edged like a ſword.

*Eroſum*, eroſe, gnawed; the border ſeems to be gnawed.

*Gibbum*, gibbous, ſwoln; both ſurfaces ſwelling to a convexity.

*Glabrum*, glabrous, ſmooth.

*Glaucum*, glaucous, grey, or of a ſea-green colour.

*Haſtatum*, halbert-ſhaped; triangular, extended wide at the baſe, narrowing to a long ſharp point at top.

*Hirſutum*, hairy and briſtly; having the ſurface covered with hairs like ſhag.

*Hiſpidum*, ſtinging; being covered with hairs, which ſtrike into the fleſh.

*Laceratum*, lacerate, or with a rent, or ragged, irregular border.

*Lanatum*, woolly.

*Lanceolatum*, lanceolate, lancet-ſhaped, or ſpear-ſhaped; narrowing gradually from the middle to each end.

*Laciniatum*, lacinate, or jagged; having ſinuſes or cuts down to the middle, divided, as it were, into ſegments, which are jagged on the edges.

*Lineare*, very narrow, and equally broad; as in roſemary, pine, fir, and the graſſes.

*Linguiforme*, tongue-ſhaped; being commonly fleſhy and compreſſed.

*Lobatum*, lobed; divided into two, three, or more lobes, termed,

——— *biloba*, two-lobed.

——— *triloba*, three-lobed.

——— *quadriloba*, four-lobed.

——— *quinqueloba*, five-lobed, &c.

*Lunulatum*, lunulate or moon-ſhaped; being ſhaped like a half moon.

*Lyratum*, lyre-ſhaped; divided into tranſverſe ſegments, the upper ones the largeſt.

*Membranaceum*, membranous; without pulp between the two ſurfaces, as in moſt.

*Nervoſum*, nervoſe; having nerves or veſſels, extending ſingly from the baſe to the extremity.

*Nitidum*, ſhining and gloſſy.

*Nudum*, naked; without any kind of hair or pubeſcence.

*Oblongum*, oblong; twice as long as broad.

*Obtuſum*, obtuſe; blunt, rounded at the extremity.

*Orbiculatum*, orbicular, round; being orbicularly round, as in *Craſſula orbiculatum*.

*Ovale*, oval, or eliptic.

*Ovatum*, egg-ſhaped.

——— *obverſe*, obverſely egg-ſhaped, by the ſmall end being affixed to the ſtalk.

*Palmatum*, palmated, or hand-ſhaped; being deeply divided longitudinally down to the baſe into ſeveral parts, ſpreading out like an open hand.

*Panduriforme*, fiddle-ſhaped.

*Papilloſum*, papilloſe, covered with pimples or veſicles, as in *Meſembryanthemum cryſtalinum*, or diamond ficoides.

*Parabolicum*, parabolical; half egg-ſhaped.

*Partitum*, partite; being divided down to the baſe, which if into two, three, four, five, or many parts, are termed.

——— *bipartite*, divided into two parts.

——— *tripartite*, divided into three parts.

——— *quadripartite*, divided into four parts.

——— *quinquepartite*, divided into five parts.

——— *multipartite*, divided into many parts.

*Peltatum*, peltate, target-ſhaped; having the foot-ſtalk inſerted into the centre of the lower ſurface, and not into the baſe, or margin, exemplified in Palma Chriſti and water-lily.

*Pentangulare*, pentangular, or five-angled.

*Pentagonum*, five-ſided; having five flat ſides.

*Piloſum*, piloſe; covered with diſtinct hairs.

*Pinnatifidum*, pinnatifid; being divided horizontally into many long ſegments, reſembling a pinnated, or winged-leaf.

*Pinnatum*, pinnated. See *Compound Leaves*.

*Planum*, plane, flat; having an even plane ſurface.

*Plicatum*, plicate, plaited, or appearing like folds, by the ſurface riſing and falling in angles, as in *Alchimella*.

*Punctatum*, punctate; dotted, or ſet with hollow points.

*Quadrangulare*, quadrangular; four-edged, or four-angled.

*Quinquangular*, five-angled; the ſame as pentangular.

*Reniforme*, kidney-ſhaped; as in common *Aſarabacca*.

*Repandum*,

*Repandum*, repand, or ſerpentine; having the edges ſinuated in a ſerpentine manner.

*Retuſum*, retuſe; blunted at the end.

*Rugoſum*, wrinkled; having the veins ſunk, ſo that the ſurface appears uneven.

*Sagittatum*, ſagittate, arrow-ſhaped; being ſhaped like the head of an arrow.

*Scabrum*, rough, rugged; having the ſurface covered with little irregular tubercles.

*Serratum*, ſerrated, or ſawed; having the edges notched like a ſaw, the indentings bending towards the top of the leaf: there are alſo,

——— *retrorſum*, ſawed backward.

——— *obtuſo*, obtuſely ſawed; having the indentings obtuſe and weak.

——— *duplicato*, doubly ſawed; having ſmall ſerratures upon the greater.

*Seſſile*, ſitting cloſe. See *Determinate Leaves*.

*Sinuatum*, ſinuated; having ſinuſes or hollows along the border or margin.

*Spatulatum*, ſpatula-ſhaped; being oblong, widening and rounded upward, but narrow below.

*Striatum*, ſtreaked, or with many ſlight longitudinal furrows or ſtripes on its ſurface.

*Spinoſum*, ſpinous or thorny; as *Acanthus ſpinoſus*, &c.

*Sulcatum*, furrowed or ridged; having a number of longitudinal ridges.

*Subrotundum*, roundiſh; almoſt orbicular, only being a little broader or larger, in ſome part or other.

*Subulatum*, ſubulate, awl-ſhaped; being broadeſt at the baſe, contracting gradually to the extremity, into a ſharp point.

*Succulentum*, ſucculent; generally thick, fleſhy, and full of moiſture, as in *Aloe*, *Cotyledon*, &c.

*Teres*, cylindric, and tapering.

*Tomentoſum*, tomentoſe; downy, cloſely covered with fine velvety down.

*Trilobatum*, trilobed, or three lobed; divided into three lobes or ſegments.

*Triangulare* triangular; forming three angles, the two loweſt being level with the baſe.

*Trigonum*, trigonal, three-ſided, or three-edged; having three ſides, and as many ſharp edges, and grow narrow from the baſe to the extremity.

*Triquetrum*, three-ſided like the former, but the ſides are flatter, and the edges not ſo prominent.

*Tetragonum*, four-ſided.

*Truncatum*, truncate; when the points ſeems to be cut off tranſverſly, as in *Liriodendron tulipifera*, tulip-tree.

*Tubuloſum*, tubuloſe, or hollow within; as in *Allium*, *Cepa*, the onion.

*Venoſum*, venoſe, veined; having many branched veſſels, like veins running through the ſurface.

*Viſcidum*, viſcid; viſcous, clammy or glutinous.

*Undulatum*, undulate, waved; riſing and falling in convexities towards the margin.

### *Compound Leaves.*

A compound Leaf, is that which is compoſed of two, three, or many ſmaller Leaves or *foliola*, ſupported on one common foot-ſtalk, which aſſemblage of folioles or lobes, if ever ſo large or numerous, on one petiola, or general foot-ſtalk, conſtitute but one Compound Leaf, *folium compoſitum*; theſe ſmaller leaves or folioles, conſtituting the compound, are, ſingly of themſelves, ſmall ſimple Leaves, varying in their form, according to the diſtinction already given, and are ſometimes furniſhed with ſhort foot-ſtalks (*petiolatum*) iſſuing from the main one, ſometimes ſeated cloſe (*ſeſſile*) to the middle rib, without any proper foot-ſtalk of their own.

Compound Leaves may be divided into three claſſes or diviſions.—1. The compound properly ſo called, being only once compounded, the *foliola* being ſupported immediately on the main foot-ſtalk.—2. Decompound, twice compounded; the foot-ſtalk dividing into leſſer, and on which the *foliola* are ſupported.—3. Supradecompound, ſeveral times compounded; the main foot ſtalk dividing into others, theſe ſubdividing into ſmaller, and on which are ſupported the folioles: each of which three claſſes of compound, admit of a variety of modifications, which gives riſe to as great a variety of terms, viz.

*Binatum*, binate; two, formed of two folioles on one foot-ſtalk.

*Ternatum*, ternate; three, having three folioles.

*Digitatum*, digitate, fingered; having ſeveral long lobes attached to the top of the foot-ſtalk, and ſpread out like the fingers of a hand.

*Quinatum*, quinate, five-lobed.

*Pinnatum*, pinnated or winged; having many folioles arranged along each ſide of the rib, or prolongation of the common foot-ſtalk like wings, as in Acacia, Sumach, and hence called pinnated or winged leaves, of which are the following modifications,

——— *cum impari*, completely pinnated; a winged-leaf terminated by an odd foliole,

liole, proceeding from the extremity of the middle rib.

*Pinnatum abrupta*, abruptly pinnated; not terminated by an odd lobe.

——— *oppoſita*, oppoſitely pinnated; the folioles ſtanding oppoſite to each other.

——— *alternæ*, alternately pinnated; the lobes placed alternately.

——— *interrupta*, interruptedly winged; the folioles being alternately larger and ſmaller.

——— *cirrhoſum*, cirrhoſe pinnated; the extremity terminated by a *cirrhi*, or claſper.

——— *decurrens*, decurrently pinnated; having the folioles running along the mid-rib from one to the other.

——— *conjugata*, conjugate pinnated; paired, the winged-leaf compoſed of one pair of folioles only.

*Decompoſitum*, decompound leaves, or twice compound; having the main foot-ſtalk divided into ſmaller, and theſe ſmaller ones ſupport the lobes.—And of this kind of compound leaves are:

*Biternatum*, or *ternatum-duplicato*, doubly three-lobed; the foot-ſtalk dividing into three ſmaller, each ſupporting three *foliola*.

——— *pinnatum duplicato*, doubly pinnated; the main foot-ſtalk, having ſmaller ones arranged on each ſide, and on theſe are arranged the folioles.

——— *bipinnatum*, doubly-winged, as the former.

——— *pedatum*, pedate, or foot-ſhaped; the foot-ſtalk divides, and has the folioles ranged on the inſide.

*Supradecompoſitum*, ſupradecompound, or ſeveral times compounded; the main foot-ſtalk, dividing into others, theſe dividing into ſmaller, and upon which are ſupported the lobes or *foliola*. And admits of the following varieties:

——— *ternatum triplicato*, triple three-leaved; the foot-ſtalk divides into three ſmaller, each of theſe into three others, and each of which ſupport three lobes or *foliola*.

——— *pinnatum triplicato*, triple-pinnated, or triple-winged; the main foot-ſtalk ſupporting ſmaller along each ſide, theſe alſo have ſmaller ones iſſuing from both ſides, and upon each ſide of theſe latter are ranged the *foliola*.

*Determinate Leaves.*

By Determinate Leaves, whether ſimple or compound, is not conſidered their figure, or ſtructure, but their place, ſituation, and inſertion on the parts of the plant, and their direction.

*Adpreſſum*, appreſſed; laid cloſe to the ſtem.

*Adverſum*, adverſe; turns its ſide towards the ſouth, not upward.

*Alternatum*, alternate; the reverſe of oppoſite, being placed ſingly one above another, gradually on each ſide of the ſtem.

*Amplexicaule*, its baſe embraces the ſtem quite round.

*Axillare*, axillary; ariſing from the angle between the branch and the ſtem, or that between the greater and ſmaller branches.

*Articulatum*, articulate, or jointed; one leaf growing on the top of another.

*Caulinum*, cauline, or ſtem Leaves; ſuch as grow immediately on the ſtalk or ſtem.

*Confertum*, confert; growing in cluſters.

*Connatum*, connate; Leaves growing oppoſite, connect or unite at their baſe appearing as one, as in ſome ſpecies of honeyſuckle.

*Decurrens*, a decurrent or running Leaf; having the baſe running along the ſtem, as in ſome thiſtles.

*Demerſum*, demerſe; ſunk under water.

*Dependens*, dependent; pointing downward to the earth.

*Diſtichum*, diſtich, two rowed; being ranged along two ſides of the branches only.

*Erectum*, erect; upright, ſo as to make an acute angle with the ſtem.

*Faſiculatum*, faſiculate; cluſters from the ſame point, as in the larch-tree.

*Florale*, floral; placed near the flower.

*Horizontale*, extended flat or parallel to the horizon; forming an exact right-angle with the perpendicular.

*Imbricatum*, imbricate; growing over one another like tiles, or ſcales of fiſhes.

*Inflexum*, inflex; turning the point towards the plant.

*Natans*, natant; floating on the ſurface of the water.

*Obliquum*, oblique; the baſe riſing upward, and the point towards the horizon.

*Oppoſitum*, oppoſite leaves; the reverſe of alternate; being ſuch as grow in pairs exactly oppoſite.

*Patens*, patent, ſpreading; recedes from the ſtem ſo as to form an acute angle therewith.

*Perfoliatum*, perfoliate; ſurrounds the ſtem or branch, without touching it with its margin or border, appearing as if perforated by the ſtem running through its diſk or middle.

*Peltatum*, peltate, ſhield-ſhaped; having the foot-ſtalk attached to the middle of its

diſk, not to the edge; reſembling the form of a ſhield, or target.

*Petiolatum*, petiolate, foot-ſtalked; having a foot-ſtalk.

*Quaternate*, four ſurrounding the ſtalk at a joint.

*Quinternate*, five ſurrounding the ſtalk at a joint.

*Radicale*, radical; ariſing directly from the root.

*Radicans*, radicant, rooting; ſtrikes root in the ground.

*Ramoſum*, rameous, a branch leaf; placed on the branches.

*Reclinatum*, reclined, bending downward; the extremity lower than the baſe.

*Revolutum*, revolute; rolled back.

*Semi-amplexicaule*, half embrace the ſtalk or branch, with its baſe.

*Seminale*, ſeminal, or ſeed-leaf; ſpringing directly from the ſeed.

*Seſſile*, ſeſſil; ſitting cloſe to the ſtem or branch, without any foot-ſtalk.

*Sparſum*, ſparſed, ſcattered; placed irregular, without any order.

*Stellatum*, ſtellate, ſtarry; ſeveral ſurrounding the ſtalk at each joint, expanding in a ſtar-like manner.

*Ternatum*, ternate; three ſurrounding the ſtem at a joint.

*Vaginans*, vaginant, ſheath-like; ſurrounding the ſtalk like a ſheath, as in the graſſes and many liliaceous plants.

*Verticillatum*, verticellate, whorled; many leaves, placed round the ſtalk at the joints, in whorls or whirls.

The foregoing liſt of the botanic terms, and ſhort deſcriptions of the various kinds of leaves, will aſſiſt in conveying an idea of their forms and determination, &c. according to the terms uſed in deſcribing them in the various ſpecies and varieties in each genera.

The Leaves furniſh very elegant and natural marks in deſcriminating the ſpecies of plants; in no part is nature more various than in the ſtructure of the Leaves, by which very numerous ſpecies are determined, and ought always to be ſtudied by the young botaniſt.

FORCING FRAME, a ſort of glaſs-caſe, or light building, fronted with glaſs Frames, in which to force flowers and fruits to early perfection, by aid of artificial heat, either of dung, tanner's-bark, or actual fire.

The general acceptation or meaning of a Forcing Frame is, a fixed erection full to the ſouth ſun; the length may be from ten to fifty, or one hundred feet; the width from five to fifteen, and from five to ten high; having an upright back wall, of wood or brick; and a front of glaſs-work, made ſometimes in one continued range of ſlope to the top of the back wall; and ſometimes with upright glaſs-work, head high, ranging immediately along the front, and from the top of which a glaſs roof is carried to the top of the back or main wall; either of which may be for univerſal uſe, for the reception of various ſorts of flower-plants, ſmall flowering ſhrubs, and dwarf fruit-trees, &c. occaſionally, to force into bloom or fruit in winter, or early in ſpring and ſummer; whereby many ſorts of the more curious flowers and fruits may be obtained ſome months before their natural ſeaſon, which will be a great curioſity, and which is effected, as aforeſaid, by aid of dung, bark, or fire-heat; the former (dung-heat) by applying it principally againſt the outſide of the back wall; the ſecond (bark heat) by forming it into a bed, in a pit within-ſide, and the third (fire-heat) by having ſeveral returns of flues againſt the inſide of the back wall for the heat to paſs along; each of which hereafter deſcribed: for theſe kind of Frames are of different conſtruction, according to the ſorts of plants chiefly intended to be forced; and the materials of heat, as dung, bark, or fuel, moſt convenient to be obtained for forcing them; ſo that the conſtruction of each kind of Frame is ſeparately exhibited.

Many of theſe Frames are employed in the vicinity of London, for forcing various plants early for market, particularly for Covent-garden, where, in early ſpring, in March, April, and May, we ſhall ſee exhibited for ſale various ſorts of flowers, fruits, and other eſculents, that would not, in their natural ſtate of growth, have appeared till June or July.

But, for private uſe, where there is a roomy pine-apple ſtove, it may alſo be uſed occaſionally, for forcing many ſorts of plants, flowers, and fruits, with equal ſucceſs, ſufficient for the ſupply of a family.

However, where conſiderable ſupply is required for market, Forcing Frames diſtinct from the pine-ſtove are alſo neceſſary.

In either of theſe departments may be introduced for forcing, pots of ſtrawberries, kidney-beans, roſes, honeyſuckles, jaſmines, and any other flowering ſhrubs; likewiſe carnations, pinks, ſweet-williams, wall-flowers, ſtock-gilliflowers, narciſſuſes, jonquil, and

and early tulip roots, and any other kind of flower-plants or roots, that may be required early for curiosity; also several kinds of curious annuals, as balsamines, gomphrenas, &c. and may likewise have several sorts of dwarf fruit-trees, as early May and May-duke cherries, peaches, nectarines, apricots, figs, grapes, gooseberries, currants, raspberries, &c.

The general construction of each sort of these Frames is exhibited under separate heads, according to the materials of heat used in forcing them, viz. by dung-heat, bark-bed heat, and by fire-heat.

*By Dung-heat.*

By Dung-heat.—This is not only the most simple and cheapest kind of Forcing Frame in its construction, but also considerably the cheapest in working, with respect to the article heat, as it may be forced effectually by substantial linings of hot-dung against the back and ends.

This Frame is formed with an upright back and ends of deal planking, and a sloping front of moveable glass-lights; the length may be ten, twenty, or thirty feet, or more; the width, from three to five, and five or six high; let the Frame work be of inch deal planking, tongued, and closely joined, that no steam from the dung may penetrate into the Frame; raised five or six feet high behind, and but ten or twelve inches high in front, raising both ends answerable to the front and back; the glass-work to range, from the upright in front, sloping upward towards the back wall, to about a foot width at top, there resting the ends upon proper Frame-work of wood, and bars or bearers three inches width, must range from the back to front, for the support of the lights, as in common hot-bed frames, and the top of all to be boarded wind and water tight; within-side may be two or three ranges of narrow shelves along the back and ends, for pots of small plants, and the bottom levelled, on which to place pots of larger kinds; or you may have shelves rising one behind another quite from the front half way up the back wall, so may place the lowest plants in front, the others in order behind them, rising gradually to the tallest in the back row.

From the above general sketch, you will easily form an idea of the proper construction of a dung-heat Forcing Frame; you may improve as you shall see convenient.

This kind of Frame is much used about London, where dung is so plenty, and easily obtained; and is there particularly used for forcing roses, or any other small flowering plants, whose flowers have merit in beauty or fragrance—may also try pots of dwarf-cherries, peaches, &c. also pots of gooseberries, currants, and strawberries, carnations, pinks, and the like; having all the sorts in pots separately, and in which they are to be placed in the Frame.

The season to begin to work this Frame, is January and February, and may be continued occasionally till May; but for any kind of fruit trees, the beginning of February is time enough, though those plants of any kind, that are designed to be forced, may be placed in the Frame a month or two before forcing time, to be occasionally protected with the glasses in hard frosts, but at other times, let them enjoy the full air till you begin forcing.

The method of working this Frame is, thus: after having placed the pots of plants in regular order, the tallest behind, and the lowest in front, &c. then put on the lights, and having a due quantity of fresh stable-dung, full of heat, prepared as for common dung hot-beds, let it be piled up close against the back and ends a yard wide at bottom, drawing it gradually into a foot width at top of the Frame, finishing it somewhat sloping, to through off wet; observing, that according as the dung settles or sinks down, a fresh supply must be added at top, to maintain the lining to the full height of the Frame.

This lining will effectually throw in a fine growing heat, and soon set all the plants in motion; observing to give air in the middle of fine days, by sliding one or more of the lights a little down; give also moderate watering occasionally in mild sunny weather, and cover the glasses in cold nights with mats.

In three or four weeks, when the heat begins to decrease considerably, it must be renewed, either by entire fresh dung, or if new dung is scarce, by shaking up the old, taking the worst away, and mix the remainder with a due quantity of new, working the whole again in a pile close against the back and ends as before, which work must be repeated every three weeks or month, or as often as you shall see occasion; for the heat must be constantly preserved to a regular brisk temperature.

A Frame of the above construction may be appropriated entirely for fruit trees, planting them in a border prepared within the Frame

againſt the back wall, and trained in the manner of wall-trees to a trellis, ranged five or ſix inches from the back erection; in which may be planted early dwarf-cherries, peaches, nectarines, apricots, grapes, figs, currants, &c. ſo may be worked by dung-heat againſt the back of the Frame as above directed; beginning in February, and continuing the glaſſes on, as well as ſupport the dung-heat until May, and there is no doubt, with good management, but that the different ſort of fruit may be brought to perfection early.

*By Bark-bed heat.*

By Bark-bed heat.—This kind of Forcing Frame is worked by aid of tanners bark hot-bed, formed in a pit within-ſide the whole length. See BARK-BED and BARK-PIT.

This Frame may be formed either of wood or brick-work, and fronted, &c. with ſaſhes of glaſs like the former; the length may be ten, twenty, or thirty feet, or more; eight or ten wide, and ſix or eight high: and may be conſtructed either nearly like the dung-heat Frame, ſix or eight feet high behind, and one in front, the ends conformable, and ſloping Frames of glaſs-work raiſed from the front, ſloping either quite to the top of the back wall, or to incline only about one half towards that part, meeting a tyled roof at top half way, which ſhould be raiſed high enough in front to throw the water off behind, as well as to admit as much ſun as poſſible to every part of the Frame; or it may be conſtructed with an upright front of glaſs, head high, and a ſloping roof of glaſs-work, ranging from the upright front, to the top of the back wall, which is rather the moſt eligible form, both for convenience and benefit of the plants; either of which conſtructions may be erected detached, or againſt a ſouth wall already built, which will ſerve for the back, and ſave ſome expence; the ends may either be of wood or brick, but would be much better if glazed like the front, &c. and the glaſs-work in every part ſhould be made to move on and off, as well as to ſlide backward and forward to give air, and to do other neceſſary work; and at one end next the back wall, may be a door to enter occaſionally; and within-ſide muſt be a pit for the bark-bed, three feet deep, continued the whole length, and width, except about a foot and half alley to go in to perform the neceſſary culture, as well as to view and gather the produce of different plants.

The pit within is to be filled with new tan any time in winter or ſpring, you intend to begin forcing, though January is ſoon enough, and the beginning of February is not too late; the bark will ſupport a growing heat three months, and if then ſtirred up to the bottom, will renew its heat, and continue it two months longer.

In this Frame may plunge in the bark-bed, pots of roſes, or any other choice flowering ſhrubs you would force into an early bloom; likewiſe may place pots of ſtrawberries towards the front and top glaſs, and pots or troughs of kidney-beans may be placed in any part of the Frame; alſo pots of dwarf fruit-trees, before mentioned, pots of double pinks, carnations, and any other moderate-growing fibrous-rooted perennials, as well as any ſorts of bulbous, or tuberous-rooted flowers, as narciſſuſes, jonquils, tulips, anemones, ranunculus, and various other ſorts.

The heat of the bark-bed will effectually warm the internal air ſufficiently to forward any ſorts of hardy flowers and fruits to perfection, at an early ſeaſon; obſerving, that, although they do not always flower and fruit ſo abundantly as in the full ground, yet, if there is but a few of any ſort, a month or two before their natural ſeaſon, they, if for ſale, will ſufficiently pay; and if for private uſe, they will always be acceptable as a rarity, and curioſity in the family.

Freſh air muſt be admitted in fine ſunny days at all opportunities, by ſliding ſome of the glaſſes more or leſs open, keeping all cloſe on nights.

Give water alſo occaſionally in moderate quantities.

When the heat of the bark declines conſiderably, do not omit forking it over to the bottom, which will revive the decaying heat ſix or eight weeks longer.

A bark-heat Forcing Frame, nearly of the above dimenſions, might be contrived entirely for forcing valuable fruit-trees, having a border within-ſide along the back wall three or four feet wide, there plant young bearing dwarf fruit trees of any ſorts before mentioned, at ſix or eight feet diſtance, in the manner of wall or eſpalier-trees, training them alſo in the ſame manner as directed for the reſpective ſorts, in their natural ſtate of growth. The bark-pit ſhould here be almoſt entirely ſunk; in the beginning of February fill the pit with new bark, which will ſoon ſet the trees into bloom, and will ripen their fruit early; and the late ſorts of fine grapes, which do not ripen kindly

kindly here in the full ground, may be brought to perfection.

But the moſt eligible general Forcing Frame for various ſorts of plants is one of the above-mentioned conſtructions, having alſo flues for fire-heat; the walls muſt be of brick-work, having three or four returns of flues formed of the ſame materials, running the whole length of the back wall within, to make fires occaſionally in ſevere froſts, or on cold nights; alſo in very cold damp weather, which will be a great improvement in very early forcing, ſo that this kind of Frame will be nearly of the plan of a ſtove or hot-houſe. See HOT-HOUSE.

In default however, of any of the above kinds of bark-heat Forcing Frames, one might be effected by a common bark-pit, ſee BARK-PIT; filling it a yard deep with tan, and in which may plunge pots of roſes, or any other ſhrubs, any ſort of low herbaceous flowering plants, fibrous, or bulbous-rooted, kidney-beans, ſtrawberries, &c.

*By Fire-heat.*

By Fire-heat.—This kind of Forcing Frame is worked by actual fire, burned in a furnace behind at one end or middle, from thence communicating the heat by flues or funnels, running the whole length of the back wall in three, four, or more returns one above another, and is often employed for ripening ſeveral of the more valuable tree-fruits at an early ſeaſon; or for forwarding ſuch to perfection, which do not ripen freely in our climate without ſuch artificial aids, particularly ſome ſorts of grapes; and in which Frame the whole bottom-ſpace muſt be good earth two ſpades deep, for the reception of the trees, &c. for they are to be planted fully in the ground.

This Frame muſt be formed of brick-work, at leaſt the back or main wall, for the convenience of having fire and flues, and the whole front, &c. muſt be glaſs like the other ſorts; the length may be from twenty to forty or fifty feet, or more, though one fire will not warm more than that length; the width may be from four or five to twelve or fifteen feet, and eight or ten high. It may be contrived either of moderate width for one row of trees only, to range againſt the back wall, or may be capacious enough to have a range of dwarf-trained trees behind, as juſt mentioned, and ſome young half or full ſtandards, ranging alſo from the back to the front, or entirely for ſtandards, eſpecially thoſe of cherries.

If it is therefore intended to have a narrow Frame for only a row of trained trees behind, the width from four to five or ſix feet is ſufficient, having the back or main wall formed of brick or ſtone, as aforeſaid, eight or ten feet high, with ſeveral flues within-ſide, returned over each other, running the whole length of the wall; in the front muſt be a low wall a foot high, on which to lay a plate of timber, and from which is ranged glaſs frames or lights in one continued ſlope to the top of the back wall, there received into proper frame-work; but, for the greater convenience, the lights may be in two tiers or ranges, an under and upper tier, the upper range made to ſlide up and down over the others, but ſo as all the glaſs-work can be moved away occaſionally, to admit the full air to the trees after the work of Forcing; the whole bottom-ſpace within this Frame, muſt be of good loamy earth, or any good garden mould two ſpades deep, which muſt be dug or trenched in the common way, then plant a range of trees within five or ſix inches of the wall, and two or three yards aſunder, erecting a trellis behind them, upon which, to train the branches as againſt a wall or eſpalier; beſides theſe trees, there may be other inferior plants ſet in the border in front of the trees, as ſtrawberries, dwarf kidney-beans, dwarf peas, mazagan beans, &c. dwarf roſes, or the like, that will not riſe high enough to ſhade the fruit-trees in the back range.

A Frame of this conſtruction, forty or fifty feet long, may be worked by one fire; but if longer, two furnaces for fires will be requiſite. For flues, &c. ſee HOT-HOUSE.

But to have a more capacious Frame both for trained trees and ſtandards, may be of any length from twenty to fifty feet or more, but muſt be ten or fifteen feet wide, having an upright back wall of brick ten feet high, with flues as above directed, and a low wall in front a foot high, on which is erected upright glaſs-work, four or five feet perpendicular, and from the top of theſe, a ſloping roof of glaſs frames, continued to the top of the back wall, ſupported upon proper bearers three feet ſix inches diſtance, having the top glaſſes in two ranges, an under and upper range, as before adviſed, both of which, and thoſe of the upright in front, made to ſlide, and move away occaſionally; in this Frame there will be room to walk under the glaſs-work in any part, and there will be alſo due room for the trees, both dwarfs and ſtandards, and then having the whole ground-

ſpace

ſpace withinſide of pliable loamy earth, as in the other Frame; you may plant your trees ſome in one range againſt the back wall, as peaches, nectarines, apricots, grapes, figs, &c. eight feet aſunder, erecting a trellis for training them upon; and in front of theſe may be planted rows of young cherries, both full ſtandards, half ſtandards, and dwarfs, the full ſtandards to have five or ſix feet ſtems, the half ſtandards three or four, and the dwarfs one or two foot ſtems; each ſort, both trained trees and ſtandards to be planted when about from three to four or five years old, as ſoon as they acquire a bearing ſtate, having regular heads of two or three feet extent at firſt planting. Having procured the trees, and the ground ready for their reception, may then plant one range of the choicer ſorts as before noticed, againſt the back wall, two or three yards aſunder, the others in rows from back to front, at eight feet diſtance, the talleſt behind and the loweſt in front, at three or four feet diſtance in each row, making each row range againſt the intervals of the trained trees behind; or if they are all full and half ſtandards, there will be more room for ſeveral ſorts of ſmaller plants under them; and as their branches will be nearer the top glaſſes, may be of particular advantage, and in the intervals may be planted ſome low currants, gooſeberries, raſberries, ſtrawberries, dwarf-beans, kidney-beans, &c. But in a frame of this dimenſions, ſome plant it entirely with ſtandards, more particularly cherries, as being more moderate ſhooters and ſooneſt arrive to a bearing ſtate, ſo as to bear any tolerable quantity of fruit to defray the expence, planting them five or ſix feet diſtance, ſometimes ſtandard plums, apricots, peaches, and nectarines are alſo planted.

A Frame of theſe dimenſions, twenty-five feet long may be worked by one fire; but if much more than thirty feet in length, two furnaces for fires, with each, its ſet of flues, will be neceſſary.

With reſpect to the age of the trees, for both the above kinds of fire heat Forcing Frames, they ſhould be from three to four or five year old, with regular heads of two or three feet extent each way, and juſt arrived at a tolerable bearing ſtate; no very vigorous ſhooters muſt be admitted, but ſuch only that aſſume a moderate regular growth, and are to be trained in the nurſery until they have acquired a proper ſize, each as directed under their reſpective genera, whether as wall trees or ſtandards, or trees proper for the purpoſe may be had at all the public nurſeries: they are to be tranſplanted into the Frame in October or November to remain for Forcing; but ſhould be permitted to have a year or two's growth here before you begin Forcing them, that they may be firmly rooted, during which time all the glaſſes ſhould be entirely away, that the trees may have the full air till Forcing time is nearly arrived.

In both the above kinds of Forcing Frames, may alſo plant ſome grape-vines on the outſide of the front glaſſes in the full ground, and their ſtems trained through holes, and conduct the ſhoots along up the inſide towards the glaſs-work to a ſort of ſlight trellis; keeping the branches quite thin, and they will ripen early fruit in great perfection.

It ſhould however be remarked with reſpect to grapes, that when intended to have in your Forcing Frame any of the large late kinds, which do not ripen here, without the aid of ſhelter and artificial heat, it will be more adviſeable to have them in a department by themſelves, becauſe they often do not ripen till late in autumn, ſo often require the glaſſes to be continued over them occaſionally all ſummer, eſpecially in wet and cold weather; and ſometimes, if the autumn proves wet and cold, they require aid again of gentle fires made them on nights, to promote their ripening perfectly; in which caſes, were other trees, whoſe fruit are ripe and gone in ſummer, planted in the ſame department, it would force them at an untimely ſeaſon, and greatly weaken them.

The ſeaſon for beginning to make the fires for forcing the trees, in either of the above deſcribed fire-heat frames, is any time in January, though about the middle, or towards the latter end of that month is, for the general part, rather the moſt ſucceſsful time to begin the general forcing, to have a good crop; for if the trees are forced very early, there will be ſome danger of their miſcarrying, as if they ſhould come into bloſſom, when ſevere weather prevails, that air cannot be freely admitted, they ſeldom ſet any tolerable crop of fruit; therefore, by beginning to make the fires about the time above directed, the trees will be in bloſſom about the middle of February, when we may expect ſome fine ſunny days for the admiſſion of a moderate portion of freſh air, which is eſſentially neceſſary to promote the natural impregnation of the fruit, and improve its free growth,

growth, for if kept too close, they are apt to drop off in their infant ſtate.

The fires are to be lighted in the furnace every evening about four or five o'clock, and if kept burning till twelve, it will ſufficiently heat the flues to warm the internal air of the houſe till next day in the evening, unleſs very cold, froſty, or cloudy damp weather ſet in, then a moderate fire may be made occaſionally alſo in a morning, but by no means force the trees too much, for a moderate warmth will prove the moſt ſucceſsful; and thus continue the fires occaſionally till April or May, but leſs in proportion as the weather grows warmer.

Freſh air muſt be occaſionally admitted in fine days, by ſliding ſome of the glaſſes a little open, and, as the trees advance to bloſſom and fruit, the days grow longer, and the power of the ſun greater, allow a greater proportion of air accordingly.

Thus your trees will be in full bloſſom in February, and ſome ſorts will ripen fruit in April, particularly cherries and ſtrawberries in plenty; you may alſo expect early apricots, peaches, and nectarines in May and June, plums and grapes in June and July, but the curious large late ſorts of grapes, which do not ripen here without ſhelter and artificial heat, will not be ripe till September; but theſe ſhould always have a ſeparate department.

After the fruit of the different ſorts are all gathered, the glaſſes ſhould be taken entirely away, that the trees may have the full air during ſummer, and in December they ſhould be placed upon the Frame again, ready for forcing in January.

With reſpect to pruning, the trained trees, i.e. ſuch that are trained as wall-trees againſt the trellis, &c. they are to be pruned and trained, every ſummer and autumn, each ſort according to its kind, as other wall-trees, and as directed under all their reſpective articles; and as to the ſtandards, their requiſite pruning is principally in autumn, to cut out any irregular growth, and thinning out any crowding ſhoots, for the branches muſt be kept thin and regular, clear of each other, ſix or eight inches diſtance; and any ſtragglers which extend in length conſiderably more than its neighbour of the ſame tree, ſhould be reduced to order; and as the branches in general become ſo long, as to preſs againſt the glaſſes, or ſpread too much, they ſhould alſo be reduced a little, to preſerve them within due compaſs, obſerving always when ſhortening the ſtandards, it is neceſſary to cut to a bud, ſituated on the outſide of the ſhoot or branch, making the cut on the inſide; but for particulars in pruning, both the trained trees and ſtandards, ſee their reſpective genera.

Every autumn, after pruning the trees, the borders muſt be digged carefully one ſpade deep.

It muſt be remarked, that the trees in theſe Frames, if annually forced, are not ſo durable, nor plentiful bearers as thoſe in the full air; therefore, when you ſhall ſee any become weak, ſickly, or bad bearers, others ſhould be ready in training, or procured from the nurſeries, to plant in their ſtead, and in this no time ſhould be loſt.

But to continue the ſame trees more effectually in health, and in a bearing ſtate, ſome have a double portion of walling and framing planted, but more particularly that of the firſt deſcribed fire-heat Frame, which is ſometimes contrived to move or ſlide along from one place to another, for one Frame-work and glaſſes to ſerve two portions of walling, ſo that being alternately worked, one part one year, the other the year after, each portion of trees will have a year of reſt in their natural growth, and will ſucceed each other in due order for forcing, whereby the health and vigour of the trees will be better ſupported, and each year a greater crop of fruit may be expected, than if the ſame trees were ſucceſſively forced every year.

FOREST TREES, ſuch large trees both deciduous and ever-greens, that grow in woods and foreſts, either naturally or cultivated, and arrive to timber, and whoſe wood is proper for any œconomical purpoſes.

Of the Foreſt Tree kind there are twenty or thirty different ſorts of deciduous and ever-greens, which may be employed as ſuch, ſome to grow to large timber for building, others to compoſe coppices of underwood, to fell every ten, fifteen, or twenty years for various ſmaller purpoſes, in huſbandry, building, and many other trades, as exhibited in the culture of the reſpective ſorts, each under its proper genus; but we have collected under this head a liſt of all the ſorts that may be employed in forming woods and other profitable plantations as timber trees, by which any one may ſee at once the ſorts proper for ſuch purpoſes; and all of which here exhibited are very hardy, and eaſily raiſed in the open ground, moſtly by ſeeds, and ſome by layers and

and cuttings; and all of them ſucceed in any open expoſure; and as in the compaſs of an eſtate, the ſituations and ſoils may be very variable, ſome parts may be mountainous, others low, ſome boggy, ſome light and ſandy, and others loamy, or of a ſtiff clayey nature, it will be eaſy to ſuit any ſort according to the ſoil in which they ſucceed beſt, which is always mentioned in their culture; and as ſuch plantations are in general great ornaments as well as improvements to eſtates, no ground, however barren or unfavourably ſituated, need lie waſte, ſince there are trees will ſuit all ſorts, and of eaſy culture; obſerving however, we only give the liſts here, of the proper ſorts, and as to their general culture, ſee each reſpective genera.

We ſhall exhibit them under two heads, viz. deciduous and ever-green kinds.

*Deciduous kinds.*

ACER, the *Maple-tree*—common-maple, greater-maple, or ſycamore-tree—Norway-maple—aſh-leafed maple.

ÆSCULUS, *Horſe-cheſtnut*—common horſe-cheſtnut.

BETULA, the *Birch-tree*—common birch-tree—*betula alnus*, or alder-tree.

CARPINUS, *Horn-beam*—common horn-beam—flowering horn-beam.

CELTIS, *Nettle-tree*—common black-fruited nettle-tree—purple-fruited nettle-tree.

CORYLUS, *Hazle-nut-tree*—common hazle-tree.

CRATÆGUS, *Wild Service-tree*—maple-leafed ſervice-tree.

FAGUS, *Beech tree*—common beech-tree—*fagus caſtanea*, or Spaniſh cheſtnut-tree.

FRAXINUS, *Aſh-tree*—common aſh-tree.

JUGLANS, *Walnut tree*—common walnut-tree—black Virginia walnut-tree.

PINUS, *Pine-tree*—*pinus larix*, or larch-tree.

PLATANUS, *Plane-tree*—oriental plane-tree—occidental plane-tree—black Spaniſh plane tree.

POPULUS, *Poplar-tree*—white poplar, or abele-tree—black poplar—trembling poplar, or aſpen-tree.

PRUNUS, *Plum-tree*, including the *prunus ceraſus*, or cherry-tree—wild black-cherry-tree—wild red-cherry tree—*prunus padus*, or bird cherry-tree.

QUERCUS, *Oak-tree*—common Engliſh oak—willow-leafed oak—cheſtnut-leafed oak.

SALIX, *Willow-tree*—common white willow—red willow—broad-leafed ſweet-ſcented willow—yellow cultivated willow—pendulous, or weeping-willow—ſallow, or oval rough-leafed willow—oſier, or long-ſhooting willow, and ſeveral others. See SALIX.

SORBUS, *Service-tree, Mountain-aſh*—common mountain-aſh, or wild *ſorbus*—ſweet or eatable ſervice-tree.

TILIA, *Lime or Linden-tree*—common green-twigged lime-tree—red-twigged lime-tree.

ULMUS, *Elm-tree*—common upright Engliſh elm—broad-leafed wych-elm—narrow-leafed wych-elm—Corniſh ſmall-leafed elm. See ULMUS.

*Ever-green kinds.*

BUXUS, *Box-tree*—common broad-leafed tree box—narrow-leafed tree box.

CUPRESSUS, *Cypreſs-tree*—ſpreading-cypreſs.

ILEX *Holly-tree*—common green holly.

JUNIPERUS, *Juniper-tree*—red Virginia cedar.

LAURUS, *Bay-tree*—common bay-tree, and varieties.

PRUNUS, *Plum-tree*—*prunus lauro-ceraſus*, cherry-bay or laurel-tree.

PINUS, *Pine* and *Fir-tree*—wild pine, commonly called Scotch fir—pineaſter, or great wild pine—ſtone-pine—ſwamp-pine—Weymouth-pine—ſpruce fir tree—ſilver fir-tree, and cedar of Lebanon.

QUERCUS, *Oak-tree*—ever-green oak—cork-tree.

TAXUS, *Yew-tree.*

THUYA, the tree of life, or *arbor vitæ*—common *arbor vitæ.*

Of the above liſt of foreſt trees, the principal and moſt valuable ſorts here as timber, are, the oak, elm, beech and cheſtnut, aſh, maples, birch and alder, poplar, plane-tree, larch, and the pine and fir-trees; but, as moſt of the other ſorts will grow in any expoſure, they might be introduced among the others here and there. In compoſing woods and other plantations for profit, they will aſſiſt both in beautifying the eſtate, and encreaſe the value, as they become fit for the ſeveral uſes for which they are calculated; ſome to ſtand for timber, others for underwood, among the reſt the willow and hazel ſhould not be omitted, they will grow any where, and will yield no inconſiderable profit; but the oak, elm, aſh, and beech are the moſt valuable of all timber-trees in this country.

Moſt

Moſt of the above ſorts are eaſily raiſed from ſeed in any common ground in the nurſery, ſome alſo by layers, others principally by cuttings, as alder, poplar, willow, and laurel.

The ſeed may be ſown in autumn, in October, or November, and ſome in ſpring, as mentioned under their reſpective articles; though all the ſorts, if the ſeeds are properly ſecured till February, may then be ſowed with good ſucceſs; when the plants are two years old, plant them either where they are to remain, or in nurſery rows, to ſtand until they are three or four feet high or more, and may then be tranſplanted for good in autumn or winter into the places where they are to remain to form a wood, &c. obſerving, it is adviſeable to have the deciduous and ever-green kinds principally in ſeparate plantations; and that if deſigned to have underwood, for falling occaſionally between the trees allotted to ſtand for timber, the deciduous kinds are chiefly to be uſed for this purpoſe; becauſe the ſtools of each falling in moſt ſorts, ſhoot forth again much freer than ever-greens; they may therefore be planted at four or five feet diſtance, and after eight or ten years growth, they will be ready to thin for the firſt falling: ever-green kinds in different plantations may alſo be planted at the ſame diſtance, and as they advance in growth, as above, may be thinned out alſo as underwood, being careful in the thinning of both kinds, deciduous and ever-greens, to leave enough of the moſt promiſing plants to grow up to timber.

But where, in a large extent of ground intended for plantations, to ſave expence in planting, the ſeeds are ſometimes ſowed at once, where the trees are to remain, to compoſe the woods, having the ground prepared by proper ploughing; drills are drawn two, three, or four inches deep, and three or four feet aſunder, the ſeeds are ſcattered in the drills, and immediately covered over; then in ſpring and autumn following, great care muſt be exerted to hoe down weeds between the rows as the plants come up.

Another method of expeditious planting is, to raiſe the young plants in the nurſery, and after two or three years growth in the ſeed-bed, plant them out in rows, a yard or four feet aſunder, and two feet diſtance in the rows.

In all large plantations there ſhould be left ſpacious opens for ridings, to different parts of the wood, as well as to admit a larger circulation of air to the trees.

In theſe plantations, by either method, great attention is requiſite to keep up good fences, and deſtroy large weeds, by hoeing, &c. till the trees are advanced in growth, and almoſt ready for the firſt fall or thinning.

The firſt fall or thinning for underwood, muſt be determined by the ſize, intended uſes, and demand for the materials; as for example, if for poles or ſuch like purpoſes, or for faggot wood, &c. they will probably be ready in ſeven, eight, or ten years, when part may be then cut down; another part the following year, ſo go on annually, till the whole plantation is cut, by which time the firſt fall will be grown up and ready to cut again, eſpecially of the deciduous kinds; obſerving at each fall, to leave the moſt vigorous and thriving trees for timber, which may be left pretty cloſe at firſt, and thinned as they encreaſe in bulk, leaving at leaſt a full crop to grow to large timber trees, ſtill preſerving the ſtools between them to cut occaſionally for underwood, every ſeven, ten, fifteen, or twenty years, according to the demand or purpoſes for which they are intended.

It ſhould be remarked, if intended to plant any boggy or marſhy grounds, that alder, poplar, and willow, are the proper ſorts which will grow very faſt either by ſmall cuttings, or by large truncheons; elder will alſo grow freely this way.

FOSSE, a ſort of ha ha, or ſunk fence, ditch-like, five or ſix feet deep, and ten, twenty, or more wide, formed at the termination of particular parts of pleaſure-grounds, parks, &c. to extend the proſpect.

Theſe kind of fences are often formed at the termination of ſpacious lawns, grand walks, avenues, and other principal parts of pleaſure gardens and parks, both to extend the proſpect into the adjacent fields and country, and give the particular parts of a garden an air of larger extent than it really has, as at a diſtance nothing of the fence is ſeen, ſo that the adjacent park, fields, &c. appear to be connected with the garden.

When a pleaſure-ground is ſituated in a park, or paddock, or adjoins to one, or any ſpacious field, open to any agreeable proſpects, the Foſſe is often continued quite round, as far as the proſpect is agreeable, either to the adjacent fields, plantation, water, or any other object appearing to view from the walks of the garden.

These Foſſes are formed upon two different plans, both however ſerving the purpoſe of a fence, and to render the proſpect open and airy.

One ſort is formed with an upright ſide next the garden, five, ſix, or ſeven feet deep, faced with a wall of brick, ſtone, or ſtrong poſt and planking; the other ſide is made ſloping outward from the bottom of the upright wall, &c. gradually with an eaſy ſlope to fifteen or twenty feet diſtance, or if more the better, ſo as to render the declivity as eaſy and imperceptible as poſſible, to take off all ſtiff and ditch-like appearance; and that if in a field or park, no ground will be loſt, as it may be converted into graſs, obſerving, that the top of the upright ſide ſhould be nearly upon a level with the adjacent ground of the garden, and always a little higher than the top of the ſlope on the oppoſite ſide, and which ſhould be laid with graſs correſponding to the adjoining garden-ground, unleſs it is thought convenient to continue a gravel walk that way; in which caſe, always preſerve a proper verge of graſs between the walk and the edge of the Foſſe; the ſloped ſide ſhould alſo have its top always on a level with the adjacent ground of the field, park, or part where it is formed; and that the ſide being finiſhed with a regular ſlope from top to bottom, it ſhould alſo be ſowed or laid down in graſs, which will preſerve the ſlope always in due form, and at all times appear decent and agreeable to the ſight.

In forming this kind of Foſſe, if, by reaſon of wet you cannot go deep enough to form the upright ſufficiently fencible againſt men and beaſts, a *cheveaux de frize* of woodwork may be erected along the top, projecting outward in a nearly horizontal poſition, or as much ſo as to riſe but very little above the level of the top of the perpendicular ſide on which it is fixed, that it may not obſtruct the view, or be very perceptible from the garden.

The next ſort of Foſſe is formed with both ſides ſloping, and in perpendicular depth from four to ſix or ſeven feet, having a fence near that height arranged along the bottom; the ſides may be ſloped gradually from the bottom, to twenty, or thirty feet width, or more at top, for the more eaſy and imperceptible the ſlope the better, but more particularly on the field ſide, for the reaſons before given, and the ſides to be alſo ſowed or layed with graſs. In this kind of Foſſe, as both ſides being ſloped, conſequently a fence along the bottom is neceſſary as a defence againſt cattle, &c. which may be either ſtrong paling, or any kind of palliſado-work, the height in proportion to the perpendicular depth of the Foſſe, for the top ſhould not be higher than that of ſlopes.

The method of forming both theſe kinds of fences is as follow:

If it be deſigned to have the firſt deſcribed Foſſe, i. e. one ſide perpendicular, the other ſloping, proceed thus: ſet out the intended width by two ranges of ſhort ſtakes, then level in the ſtakes by notching, according to the intended height of the top on each ſide, corroſponding with the adjacent ground as aforeſaid; and then make up both the top lines with earth firmly, according to the line of level marked on the ſtakes; this done, then cloſe along the ſide of the line of the intended upright ſide, proceed to dig a trench three feet wide, perpendicularly to the intended depth of the Foſſe; as you go on, work alſo the ſloping ſide gradually down, ſtill continue digging the trench perpendicularly next the garden, &c. till arrived at the proper depth; then level the bottom equally along according to the lines of level at top, and having proceeded ſo far, then, according to the line of level at top and bottom, trim and finiſh off the ſloping ſide regularly, ſo as to form an even ſlope from the outſide line at top, to that at bottom: as to the upright ſide, a wall muſt be erected to the height of the line of level at top; making good the ground behind the wall, firmly, as the building advances, and finiſh the top with a coat of turf level with the adjoining ground; at the ſame time finiſh alſo the ſlope, either by ſowing it with graſs-ſeed, or laying it with turf as ſhall be moſt convenient.

To form the other ſort of Foſſe, with both ſides ſloping: ſet out the width by two lines of ſtakes, level them in, and make up the ground of each line according to the mark of level, as directed before in the former; then exactly along the middle, between the two lines of ſtakes, dig a trench two or three feet wide, to the intended depth of the fence, ſloping each ſide a little as you go on, ſtill continuing the trench perpendicularly, till arrived at the due depth; then, as in the former, level the bottom an equal depth, by ſtakes agreeable to the lines of level at top: when this is effected, finiſh off both ſlopes evenly from each line of level at top, to that at bottom, and ſow each ſlope with graſs or turf

turf as you ſhall think proper; and with reſpect to the fence along the bottom, it may be either cloſe paling, rails, or paliſadoes, as is moſt convenient, the height proportionable to the depth of the Foſſe, but not to be higher, or at leaſt but very little above the line of level at top of the Foſſe.

FRAGARIA, the ſtrawberry plant.

The plants are low, herbaceous, hardy perennials, growing in large leafy tufts, cloſe to the ground, producing ſlender annual ſtalks a few inches high, crowned by many beautiful fruit of admirable fragrance; hence it derives the general title *Fragaria*.

Claſs and order, *Icoſandria Polygynia*.

*Characters.*] CALIX is monophyllous, plane, and ten-parted at top. COROLLA, five roundiſh ſpreading petals, attached to the calix. STAMINA, twenty ſhort awl-ſhaped filaments, and moon ſhaped antheræ. PISTILLUM, numerous germina, collected into a head, and many ſtyles, having ſimple ſtigmas. PERICARPIUM, none, but a roundiſh large ſoft receptacle, or fruit, having numerous ſmall ſharp-pointed ſeeds ſcattered over its ſuperficies.

There is but one real ſpecies of the common ſtrawberry, which is comprehenſive in many varieties of its fruit.

The ſpecies are;

1 FRAGARIA *Veſca*.

*The cultivated Strawberry.*] Fragaria, with a thick fibrey root, crowned by a large cluſter of oval-lobed leaves, many trailing ſtrings or runners rooting and forming plants at every joint; and amidſt the leaves ſeveral ſlender flower-ſtalks, ſix or eight inches high, crowned by a cluſter of ſmall white flowers, ſucceeded by large roundiſh berries of different ſizes and colours in the varieties.

The principal *Varieties* are:

*Wood Strawberry (Sylveſtris.)* Having oval ſawed-leaves and ſmall round fruit, and of which there are—red-fruited wood-ſtrawberry—white wood-ſtrawberry—greeniſh pine-apple taſted wood-ſtrawberry—double-bloſſomed wood-ſtrawberry—and with gold ſtriped-leaves—ſilver-ſtriped leaves.

*Scarlet, or Virginia Strawberry (Virginiana.)* Having oblong, oval, ſawed-leaves, hoaryiſh underneath, and a roundiſh ſcarlet fruit; and of which there are—common ſcarlet ſtrawberry—roundiſh-leafed large ſcarlet-ſtrawberry—ſtriped-leafed ſcarlet-ſtrawberry.

*Hautboy, or Muſky Strawberry (Moſchata.)* Having oval-lanceolate, rough leaves, and large, pale, red fruit; of which there are—oval fruited hautboy-ſtrawberry—globular-fruited hautboy—pine-ſhaped hautboy—green-fruited hautboy—red-bloſſomed hautboy—white-ſtriped-leafed hautboy—yellow-ſtriped-leafed hautboy.

*Chili Strawberry (Chiloenſis.)* Having large oval, thick, hairy leaves, large flowers, and very large firm fruit; of which there are—round, pale-red Chili ſtrawberry—oblong, pale-red Chili ſtrawberry—round, ſcarlet Carolina ſtrawberry—white Chili ſtrawberry. Theſe Chili ſtrawberries were firſt introduced into Europe from Chili, in America; they are conſiderably the largeſt fruit of all the ſtrawberry kind, though not always good bearers, but I have ſometimes had them bear wonderful great crops, even ſuperior to the ſcarlet kind; and for the ſingularity of their large beautiful fruit, ſhould never be omitted in the ſtrawberry collection.

*Alpine, or Monthly Strawberry (Alpina.)* Having ſmall oval leaves, ſmall flowers, and moderate-ſized, oblong, pointed fruit, of which there are—ſcarlet Alpine ſtrawberry—red Alpine ſtrawberry—white Alpine ſtrawberry. Theſe varieties grow naturally on the Alps; they poſſeſs this ſingular property more than the other ſorts, that all the young plants, formed every ſummer, upon their runners, ſhoot up into flower and fruit the ſame year, whereby a freſh crop of fruit is continued monthly in the old and new plants, from June until November or December; the plants are always great bearers, and proſper any where, and the fruit is of a fine poignant agreeable flavour.

All the above varieties of *Fragaria* are hardy low perennials, durable in root, but the leaves and fruit-ſtalks are renewed annually in ſpring; ſhooting up to flower in May and June, and their fruit arrive to perfection in June, July, and Auguſt, and which in the Alpine kind as aforeſaid, continue till the beginning of winter. They all proſper in any common garden ſoil, producing abundant crops annually, without much trouble, and encreaſe exceedingly every ſummer, both by off-ſets or ſuckers from the ſides of the plants, and by the runners or ſtrings, all of which rooting and forming plants at every joint, each of which, of either ſort, ſeparately planted, becomes a good plant the ſame year, and produces a few fruit the year following, but bear in great perfection the ſecond ſummer; tho' young plants of the Alpine ſtrawberry, planted

out ſoon after they are formed, bear fruit the ſame ſeaſon, as will alſo the runners of them; for this ſort is the moſt prolific of all the varieties of *Fragaria* yet known, as not only its runners form plants at all the joints as they go on like the other ſorts, but the ſame young plants, as before obſerved, ſhoot up into flower and fruit, and the fruit alſo attains good perfection the ſame ſeaſon; which in all the other ſorts, the young plants rarely produce fruit until they are one year old, and ſometimes not till they have two years growth.

All the ſorts are commonly cultivated in kitchen-gardens, in beds or borders of common earth, in rows length ways, fifteen or eighteen inches diſtance; the plants the ſame diſtance from one another in each row.

Patches of the different ſorts diſpoſed here and there in the fronts of the different compartments of the pleaſure-ground, will appear ornamental both in their flowers and fruit, and effect an agreeable variety.

A plantation of ſtrawberries will endure ſeveral years, obſerving however, that the plants are always in the greateſt perfection of bearing in the ſecond, third, or fourth years; therefore, to have plentiful crops of large handſome fruit, a freſh plantation ſhould be made every third or fourth year, for altho' the plants may continue healthful and ſtrong much longer, and flower abundantly, yet moſt of them are apt to become ſterile, i. e. produce flowers deficient in ſome of their generative parts, particularly the *piſtillum*, or female organs either in whole or part, in which caſe they produce none, or at beſt, but very ſmall irregular fruit; and young plants taken from ſuch for propagation, retain the ſame degree of ſterility of the parent.

The flowers of all the varieties of ſtrawberries have each five ſmall roundiſh petals, and are hermaphrodite, and not male and female in different plants, as advanced by the author of the Univerſal Botaniſt; for as both the male and female organs are contained in the ſame flower upon the ſame plant, they muſt conſequently be hermaphrodite, and the claſs and order determine it: *Icoſandria Polygynia*, twenty ſtamina and many ſtyles.

The earlieſt ſorts are the ſcarlet Alpine, and the white and red wood varieties; the hautboys next, and the Chili laſt of all, but they all attain perfection in June and July.

But they may alſo be obtained at a much earlier ſeaſon by aid of artificial heat, even in winter and ſpring: ſee their culture in HOT HOUSE, &c.

*Propagation.*

The propagation of ſtrawberries may be effected by ſeed, particularly to obtain new varieties; but the common method of propagation is by young plants which all the ſorts furniſh abundantly, both by off-ſets from their ſides, and runners or ſtrings, which, rooting as they go on, form plants at each joint, and thoſe, both of the off-ſets and runners, become proper plants the ſame year, fit for forming a new plantation the following autumn, always making choice of thoſe young plants near the old root.

The ſeaſon for this work is any time in autumn, Auguſt, September, or October, but the ſooner the better, or if omitted in autumn, it may be done in ſpring, but I greatly prefer an early autumn planting, for the plants will be much ſtronger and better prepared to produce a few fruit the following year, which is rarely the caſe with the ſpring-made plantation; but to have a ſupply of as good plants as poſſible, it is proper in June, July, or beginning of Auguſt, to take off a quantity of the firſt formed young plants, particularly thoſe formed neareſt the parent, raiſing them up carefully with fibres, and trim off all the ſtrings or running part, then plant them in a ſhady border by way of nurſery, ſix inches apart, give a good watering and repeat it often in dry weather, and by September or October they will be ſtrong and in much finer order for planting out for good, then thoſe that remain till that time in the beds. If you however ſhould omit the above method, I would adviſe, if poſſible, in Auguſt or September to take opportunity of ſhowery weather, and make a plantation at once in the places where they are to remain; but by no means be later than October, otherwiſe the plants will not take root ſufficiently before winter, and will be liable ſome to be thrown out, others forced into the ground during that ſeaſon, by the weather and vermin; and at any rate will be ſo weakly in ſpring, as not to produce any fruit the enſuing ſummer. As to a ſpring plantation, it may be performed, if thought convenient, when omitted in autumn, but the plants will ſcarce produce fruit that year; they however will have the ſummer before them to acquire ſtrength before winter, ſo as to be able to produce ſome fruit the next ſeaſon.

In

In the choice of the plants for making your plantation, by no means take them from very old beds, but ſuch that are in the ſecond or third year of their bearing, and that are remarkable for bearing plentifully, becauſe, as before noticed, ſome plants may appear very healthful, and flower ſtrong, yet produce but very little fruit, occaſioned by moſt of the flowers being deprived of the female organs, for they frequently have numerous ſtamina and no ſtyle; obſerve likewiſe, in taking off the young plants, that of ſuch off-ſets or ſuckers you may take immediately from the ſides of old plants, to chuſe thoſe ſituated quite on the outſide; and that are only of one ſummer's growth, rejecting ſuch that have knobby hard roots; and of plants produced from the runners, chuſe principally thoſe robuſt ones, which grow next the parent plant, thoſe at a diſtance toward the extreme part of the runner are not near ſo proper; being careful to raiſe them up with as much root as poſſible, trim off all ſtringy parts, broken leaves, and ſtraggling fibres, and they are ready for planting.

A free ſituation open to the full ſun is rather neceſſary for theſe plants, principally to give the fruit flavour; though, for the ſake of continuing a longer ſucceſſion, ſome of the wood, ſcarlet, and Alpine kinds may be planted in different expoſure to have more or leſs ſun.

With reſpect to ſoil and its preparation, all the ſorts will ſucceed in any common garden earth, as before obſerved; but if it is inclinable to a loamy nature, it will be a particular advantage; however, be in no great anxiety about ſoil, take what your garden affords, and if very poor, add ſome rotten dung, and dig the whole one ſpade deep; then form the ground into beds four feet wide with two feet wide alleys between bed and bed, for the convenience of having always ſufficient room to go in to hoe, dig, weed, water, and gather the fruit; but do not form the alleys deep, only juſt tread them out by line, then rake the beds over, and line the edges ſtraight; or you may prepare borders by the ſides of walks for the reception of ſome of each ſort, where they will be both profitable and ornamental.

Having the ground and plants ready, then proceed to plant them by line and dibble, in rows lengthways, the bed or border fifteen inches diſtance for the wood, eighteen for the ſcarlet hautboys and Chili kinds; I would alſo adviſe the rows of Alpine ſtrawberries to be a foot and a half diſtance, for although the plants are of more humble growth than the three laſt mentioned, yet, as they ſend forth many runners, and as theſe are prolific the ſame ſeaſon, let them have room, that their runners may have full ſcope to root and fruit as they advance; and thus by allowing all the ſorts room, you will find your account in the ſize, quantity, and quality of the fruit; and to give them ſtill greater ſcope, let each ſort be planted in the quincunx order.

As ſoon as planted, let them all have a plentiful watering, to ſettle the earth cloſe about the roots, which repeat occaſionally in dry weather for a week or two, till they have taken good root.

*General Culture.*

Having thus formed your ſtrawberry plantation, we proceed to give direction for their future culture.

The firſt ſeaſon of planting requires nothing material to be done till ſpring, more than lightly hoeing between the plants to deſtroy any autumnal weeds, they requiring no covering in winter; and in ſpring, in February, or March, when weeds ariſe, go over all the ground with a hoe, both to cut up all weeds, and to looſen the ſurface about the plants; and as in April, May, and June, and during the ſummer, all the ſorts encreaſe conſiderably by off-ſets, as alſo by their numerous ſtrings or runners, advancing a conſiderable diſtance, rooting and forming plants at every joint, ſo as to overſpread the ground, and greatly croud the principal plants if not diſplaced; therefore, according as theſe runners are produced, it would be of particular advantage to diveſt the plants of the groſſeſt of them, which will greatly ſtrengthen the crop, and promote fruitfulneſs both in quantity and ſize; let them however, at any rate be cleared from all runners in autumn, cutting them away cloſe to the plants; clear off alſo all weeds, and then they will remain clean and decent until the return of ſpring again, when the work of hoeing the beds and ſtringing the plants muſt be occaſionally repeated during ſummer and autumn; which operation ſhould be performed every year, and if in every autumn after the firſt, the alleys are dug, and ſome earth ſpread between the plants, it will prove very benficial, as directed below.

The ſecond year of their growth you may expect a general bloſſom and full crop of fruit.

Every

Every ſummer, when the plants are in bloſſom, if the weather ſhould then prove dry, good watering is abſolutely neceſſary, which ſhould be continued plentifully every day or two, from the firſt appearance of the bloſſom till the fruit is ſet and advanced conſiderably in growth; otherwiſe the bloſſom, though abundant, will drop without ſetting half a crop of fruit, and that which ſtands will not attain its due ſize; but if a moiſt ſeaſon happen at the above period, watering is unneceſſary, and a plentiful crop always ſucceeds.

The ripening of the fruit advances gradually in June, July, and Auguſt, continuing in ſucceſſion in different ſorts, ſix weeks or two months, though in the Alpine kinds, is often continued from June till the beginning of winter.

In gathering the fruit, let it always be taken with about an inch of its ſtalk, pinching it off, and put it in ſmall baſkets, not in too great quantities, leſt they bruiſe one another.

When they are to be ſent to market, they ſhould be packed in pottles, i.e. long, upright, narrow chip baſkets, holding about a quart or three pints, having a bow-handle at top, and each when filled, ſhould be papered over, and tied down with baſs; then many of theſe pottles ſhould be packed upright in a large flat boat-baſket, and ſent to market on men's head, that they may go ſafe without bruiſing, as is the practice of the London gardeners, ſome of whom have ſeveral acres of ground entirely ſtrawberries, particularly thoſe in the neighbourhood of Hammerſmith and Brentford.

As the plants being now arrived at a full bearing ſtate, here follows ſome general hints concerning their annual culture. Every ſpring, in February, or March, provided the plants have been ſtringed the preceding ſummer and autumn, to preſerve them in diſtinct bunches, it will prove very beneficial to looſen the earth, by fork-digging lightly, between the rows, being careful to break the lumps, and preſerve an even ſurface; as the ſummer advances, hoe down weeds according as they appear; and as many runners will always riſe from the plants, it will ſtill be of advantage, when opportunity ſuits, to clear them conſtantly off all the fore-part of ſummer, until the fruit has obtained its growth, except the Alpine kinds, which, as formerly obſerved, produce fruit the ſame year, as well as the old plants, ſo that a due quantity of runners ſhould be retained to each plant to furniſh a greater ſucceſſion of fruit during the ſeaſon; likewiſe of the other ſorts, when intended to have a ſupply of young plants for a future plantation in autumn, ſome of the beſt runners ſhould be reſerved to form plants for that purpoſe. In autumn, after the fruit is gone, give the beds a general dreſſing, that is, mow or cut down the old leaves, and rake them off, then with a knife or ſharp hoe trim off all the remaining runners from each plant, cutting up alſo all thoſe between them, and all weeds, and draw the rubbiſh into the alleys, and thus you will form all the plants into diſtinct bunches; then line out and dig the alleys, burying the rubbiſh in the bottom, and ſpread a little of the earth between the bunches of plants, which will exhibit an air of neatneſs, as well as prove a very beneficial dreſſing, and no farther care is neceſſary till ſpring; when the work before directed in ſpring and ſummer may be again repeated, the ſame alſo again in autumn, and ſo proceed annually.

Obſerve however, that if the work of ſtringing the ſtrawberry-beds as above in ſummer and autumn, ſhould be omitted at theſe ſeaſons, do not fail to do it effectually in ſpring, in February or March, as above directed in the autumn dreſſing, digging the alleys and earthing between the plants in the ſame manner.

Many perſons however never beſtow much culture on their ſtrawberries, but ſuffer their runners to ſpread about, and remain from year to year, covering the whole ground, and form apparently a perfect ſward; but the fruit of ſuch plants will be very inconſiderable, both in reſpect to ſize and quality, in compariſon to thoſe regularly dreſſed annually.

Some perſons again direct the beds to be covered every winter with coal-aſhes, caſt-off bark of the ſtoves, leaves of trees, or ſuch like materials, to protect the plants from froſt; but this is intirely unneceſſary, for the plants are generally hardy enough to reſiſt the ſevereſt winter's cold.

*Forcing them in Hot-houſes, &c. for early crops.*

Strawberries may be brought to early perfection by aid of a hot-houſe, forcing-frame, glaſs-caſes againſt hot walls, or in common dung hot-beds under frame and glaſſes, by which ripe fruit may be obtained in January, February, March, or April; the ſcarlet and Alpine,

Alpine, and wood kinds are the moſt eligible for this purpoſe.

For this purpoſe of forcing, you ſhould be furniſhed with one or two-year old plants, that is, young plants of off-ſets or runners before deſcribed, planted into pots or nurſery-beds towards autumn, and ſuffered to take their growth in the open air till the following winter twelve-month: they will then be of proper ſize for forcing; therefore, in autumn, at the times directed for the natural crops, plant out a quantity of ſtout young plants either into nurſery-beds a foot aſunder, or into pots, thirty-twos, and place them in the ſhade till well rooted, which in November plunge to their rims in a warm border under a wall or hedge, to remain until April, then replunge them in a ſhady border for the ſummer, ſupplying them plentifully with water; do not omit this, and pull off all runners and flowers. In September tranſplant them with the balls of earth into larger pots, twenty-fours, to remain to fruit; and thoſe in nurſery-beds, in the open ground may alſo be now be tranſplanted with balls into the ſame ſized pots to remain for fruiting, giving ſtill plenty of water during the dry warm weather; and towards the latter end of October remove them to a warm ſituation, or into a common frame, where they may be occaſionally ſheltered from the inclemency of hard weather till December, January, or February, to prepare them the better for forcing at theſe times.

Having the plants ready as above, then, towards the end of December, or in January, or February, according to the time the fruit is required, place ſome pots of plants into the ſtove or forcing-frame, and either plunge them in the bark-bed, if you would have them as forward as poſſible, otherwiſe place them upon the ſhelves, &c. obſerving always to place them as near the front glaſſes as poſſible, for they rarely ſucceed in the back parts, unleſs placed upon high ſhelves near the top lights.

Their culture here is only regular watering twice or thrice a week, juſt to preſerve the earth moderately moiſt; and you may expect fruit in February and March, or indeed earlier, by beginning to force ſooner accordingly.

If you have the convenience of hot-walls covered with glaſs frames, for forcing fruit-trees, &c. the ſtrawberry plants may in October be turned entirely out of the pots into the border between the trees, a foot aſunder, where they will be firmly rooted by the time for beginning to force the trees, and the ſame fires will do for the whole.

But where there are not the convenience of hot-houſes, &c. the plants may be forced upon dung or tan hot-beds under common hot-bed frames, or in bark-pits, &c.

The hot-beds may be made in January or February, the width and length of the intended frames, and about three feet perpendicular in thickneſs, placing the frames, &c. on, and when the firſt flaſh of great heat is over, put in the plants, previouſly, if dung hot-beds, laying in ſome earth or old tan, in which to plunge the pots, placing them as cloſe together as they can ſtand, filling up cloſely between all the pots, and as ſoon as done put on the lights; every day admit freſh air by tilting the upper ends of the glaſſes an inch or two, being careful to examine the heat; if too powerful, draw up the pots proportionably, to prevent ſcorching their roots; and when the heat is much decreaſed, line the bed, if of dung, as directed for cucumbers, &c. when the plants come into bloſſom they may be moved in their pots to freſh hot-beds, to bring them forwarder, or where this is not convenient, they may be retained in the ſame bed, by ſupporting a proper heat, by lining both ſides occaſionally with ſubſtantial linings of hot dung, covering the glaſſes on nights with mats, ſtill admitting freſh air daily at all opportunities, and give due ſupplies of water; and thus you may have plenty of ſtrawberries towards the end of March and in April.

FRAMES, hot-bed Frames, and other moveable Frames furniſhed with glaſs covers or lights at top, uſed in gardens for protecting and forwarding tender and early plants.

Theſe Frames are formed of inch or inch and quarter deal-board, made about three yards and half long, and one and a half wide, as high again in the back as in front, to give the top a due ſlope to the ſun, and proper declivity to carry off the wet, which muſt be covered with glaſs lights to move on and off occaſionally.

But with reſpect to particular dimenſions, they are different according to the ſorts of plants they are intended to protect; but generally from ten to twelve feet long, four and half wide, and from eighteen inches to three feet ſix high in the back, and from nine to eighteen inches in front, the ends made ſloping anſwerably from the back to the fore-part; each Frame is furniſhed with three glaſs ſaſhes,

ſaſhes, commonly called lights, for the top to move on and off, and ſlide up and down occaſionally; but beſides theſe three-light Frames, one or more two-light, and a one-light Frame of proportionable ſize may alſo be neceſſary for ſmaller purpoſes, ſuch as for ſeed and young ſeedling plants to nurſe them till large enough for the larger Frames; but as the moſt common Frames for general uſe are thoſe uſed in kitchen gardens, in the culture of cucumbers and melons, which alſo ſerve occaſionally for various other plants, both eſculent and flowers, we ſhall firſt exhibit the particular dimenſions of ſuch kind of Frames, then deſcribe the others for particular uſes.

The common kitchen-garden Frames may be of three different ſizes, i. e. for one light, two lights, and three lights; the latter of which however are the moſt material, and which are employed for general uſe, but it is neceſſary alſo to have one or more one-light and two-light Frames, eſpecially in private gardens, the former as a ſeed Frame, for a ſmall hot-bed, particularly for the ſeeds of cucumbers and melons for the early crops; and the two-light one as a nurſery Frame to the young plants of the ſame kinds, &c. to forward them to a due ſize for the three-light Frame.

The one-light Frame therefore may be about four feet and a half width from back to front, and three feet ſix the other way, fifteen or eighteen inches high in the back, and nine in front, with a glaſs ſaſh or light, made to fit the top completely, to ſlide up and down, and move away occaſionally.

The two-light Frame may be ſeven feet long, four and half wide, and fifteen or eighteen inches high in the back, and nine in front, having one croſs bar, three inches width, ranging from the middle of the back at top, to that of the front, ſerving both to ſtrengthen the Frame, and help to ſupport the lights; the two lights to be each three feet ſix wide, made to fit the top of the Frame exactly.

The three-light Frames ſhould be ten feet ſix inches long, four and a half wide, and from eighteen inches to two feet high in the back, and from nine to twelve or fifteen inches in front; obſerving that thoſe deſigned principally for the culture of melons, may be rather deeper than for cucumbers, becauſe they generally require a greater depth of mold or earth on the beds, though Frames eighteen or twenty inches in the back, and from nine to twelve in front, are often made to ſerve occaſionally, both for cucumbers and melons; each Frame to have two croſs bars ranging from the top of the back to that of the front, at three feet ſix inches diſtance, to ſtrengthen the Frame, and ſupport the lights, and the three lights to be each three feet ſix inches wide; the whole together being made to ſit the top of the Frame exactly every way in length and width.

Sometimes the above ſort of Frames are made of larger dimenſions than before ſpecified, but in reſpect to this, it ſhould be obſerved, that if larger they are very inconvenient to move to different parts where they may be occaſionally wanted, and require more heat to warm the internal air, and in reſpect to depth particularly, that if they are but juſt deep enough to contain a due depth of mold, and for the plants to have moderate room to grow, they will be better than if deeper, as the plants will be then always near the glaſſes, which is an eſſential conſideration in early work, and the internal air will be more effectually ſupported in a due temperature of warmth, for the deeper the Frame, the heat of the internal air will be leſs in proportion, and the plants being far from the glaſſes will be ſome diſadvantage in their early growth; beſides, a too deep Frame, both in early and late work, is apt to draw the plants up weak, for they always naturally aſpire towards the glaſſes, and the more ſpace there is, the more they will run up, for which reaſon the London kitchen gardeners have many of their Frames not more than fourteen or fifteen inches high behind, and ſeven in front, eſpecially thoſe which are intended to winter the more tender young plants, ſuch as cauliflower, lettuce, and for raiſing early ſmall ſallad-herbs, raddiſhes, &c.

But Frames deſigned for the protection of taller plants, ſhould be deeper in proportion, as for example, if deſigned as a nurſery Frame for young pine-apple plants, three feet ſix by fifteen, or eighteen, will be the proper depth; arranging the largeſt plants behind, the young yearling ones more forward, and the crowns and ſuckers of the year in the front of all; a Frame of this dimenſion may ſerve alſo for any of the hardier kinds of low green-houſe plants, as myrtles, &c. either in default of a proper green-houſe, or as an eaſement to one when too much crowded.

A drawing Frame for annuals, i. e. for drawing the larger ſorts to a tall ſtature, ſuch as the *Coloſia criſtata*, or cock's-comb, and the *Amaranthus*

*Amaranthus tricolor*, &c. the Frame for this purpoſe is ſometimes made as deep as it is intended to draw the plants in height, and is ſometimes compoſed of three, four, or more different Frames of equal width and length, to place upon one another occaſionally, as the plants advance in ſtature; the former is ſometimes made four, five, or ſix feet high in the back, and three, four, or five, in front, but the front ſhould be glazed to admit the light and heat of the ſun, otherwiſe the Frame would form a kind of deep pit, which would draw the plants up too faſt into ſmall weak ſtems, and they would alſo be apt to loſe all their lower leaves: that part ſhould alſo be made to open occaſionally, for giving water, or a larger portion of air in hot weather; the mode of uſing this Frame is, that after the plants are drawn about a foot and a half high in any common hot-bed Frame, another hot-bed is made for the deep Frame, in which the plants are placed to remain to grow to their full ſtature. The other ſort of drawing Frame is frequently called a multiplying drawing-Frame, as being compoſed of different parts, one of the parts may be of the dimenſions of a common hot-bed Frame, eighteen inches by nine or ten deep, and on this the glaſſes are to be placed; the other parts for multiplying the depth occaſionally, muſt be each exactly the ſame width and length of the firſt, and a foot deep on every ſide: and as to the mode of uſing them, the firſt or principal Frame having the glaſſes, is placed firſt on the bed, and when the plants have reached the glaſſes, remove this Frame off the bed, and place on one of the others, then place the firſt Frame and glaſſes upon that, and as the plants again advance in height, another multiplyer muſt be added, and after that another, always ſtill having the principal Frame with its glaſſes uppermoſt, obſerving, that if the front of each of theſe Frames, both the principal one and multiplyers were glazed, to admit the light and heat of the ſun, it would greatly improve the growth of the plants. Another ſort of drawing Frame may be formed thus: having one of the common hot-bed Frames with its lights, place it upon the bed, and having four ſtout poſts, one fixed at each corner cloſe to the Frame, four or five feet high, in which are bored holes ſix inches diſtance, and four iron or wooden pins are provided, one for each poſt, and when the plants arrive at the glaſſes, the Frame is drawn up a little, and the pins fixed in the holes, then reſt the bottom of the Frame upon the pins; and continue raiſing it from time to time as the plants advance higher. The vacancy at bottom may be eaſily cloſed up with boards or garden-mats, and if the front was cloſed with oiled paper to admit the light, it would be an advantage; it is alſo proper to have the front to open occaſionally for giving air and water.

In all the ſorts of Frames of every dimenſion here ſpecified, the wood-work of the back, ends, and front, ſhould be of inch or inch and quarter deal, as before obſerved, which ſhould be all neatly planed even and ſmooth on both ſides; and the joints, in framing them together, ſhould be ſo cloſe that no wet nor air can enter; the croſs-bars or bearers at top, for the ſupport of the glaſſes ſhould be about three inches broad and one thick, and neatly dove-tailed in at back and front even with both edges, that the lights may ſhut down cloſe, each having a groove or channel along the middle, to conduct off all wet falling between the lights: at the end of each Frame at top, ſhould be a thin ſlip of board four inches broad, arranged from back to front, joining cloſe up to the outſide of the lights, which being neceſſary to guard againſt cutting winds, ruſhing in at that part immediately upon the plants, when the lights are occaſionally tilted behind for the neceſſary admiſſion of freſh air, &c.

With reſpect to the lights, the wood-work of the Frame ſhould be inch and half thick, and two and half broad; and the bars for the immediate ſupport of the glaſs-work, ſhould be about an inch broad, and not more than inch and half thick, for if too broad and thick, they would intercept the rays of the ſun, ſo ſhould be only juſt ſufficient to ſupport the glaſs-work without bending, and ſhould be ranged from the back part to the front, eight or nine inches aſunder.

All the wood-work, both of the Frames and lights, ſhould be painted in oil, to preſerve them from decay; a lead colour will be the moſt eligible, and if done three times over, outſide and in, will preſerve the wood exceedingly from the injuries of weather, and from the moiſture of the earth and dung.

The glaſs-work of the lights may either be laid in lead and well trimmed with cement, air and water tight; or may be laid in the bars of wood in putty, *imbricatum*, i. e. overlaid, or lapping at the ends; the latter method is by ſome preferred, as being more effectual for the diſcharge of wet, and the

imbricatures or lapping of the panes being by ſome left open or unputtyed at bottom, that the rancid vapour naturally ariſing in hot-beds, and all condenſed drops againſt the glaſſes, may be diſcharged at theſe places, as well as admit a perpetual moderate current of freſh air, proves very beneficial to all plants: this mode however of leaving the lappings open, is by ſome objected againſt, eſpecially for very early work, on account of the too free admiſſion of air in cold weather; I however have uſed them with great ſucceſs at all ſeaſons, though in the kitchen-gardens about London, where there are vaſt quantities of framing always at work, their lights are, for the general part, laid in lead, in panes about ſix or eight inches ſquare: in either method of glazing the beſt ſort of white glaſs ſhould be uſed, and the greateſt care exerted to make the whole perfectly water-tight.

FRAXINUS, the Aſh-tree.

There are three ſpecies, all hardy deciduous trees, one of them a lofty foreſt tree, the others of lower growth, uſed principally in ornamental plantations, all of them adorned with compound leaves of ſeveral pair of lobes terminated by an odd one.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] CALIX, hermaphrodite and female flowers on the ſame and on different trees, having ſometimes ſmall monophyllous cups, and ſometimes none. COROLLA, either none, as in the common aſh; or, as in ſome ſpecies, four narrow petals. STAMINA, two ſhort filaments, and oblong antheræ. PISTILLUM, an oval germen, erect ſtyle, and bifid ſtigma. PERICARPIUM, a compreſſed fruit, having a ſingle, ſpear-ſhaped compreſſed ſeed.

The fruit of the aſh are commonly called aſh-keys.

The ſpecies are;

[1]FRAXINUS *excelſior.*

*Moſt lofty or common aſh-tree.*] Fraxinus, with a large upright grey ſtem, riſing ſixty or ſeventy feet high, branching upward into a full regular head, garniſhed with large compound leaves of five pair of ſawed lobes, terminated by an odd one, and ſmall greeniſh flowers without petals.

*Varieties.*] With ſilver-ſtriped leaves—gold-ſtriped leaves.

[2]FRAXINUS *Americana.*

*American Aſh. Varieties* of this are;

*Black American Aſh*,—having an erect ſtem, branching twenty or thirty feet high, large very dark leaves, compoſed of three or four pair of lobes, and an odd one; ſmall greeniſh flowers, and broad blackiſh fruit.

*White American Aſh*—having an upright whitiſh ſtem and branches, growing twenty or thirty feet high, light green leaves, compoſed of about three pair of obtuſely ſawed lobes, placed far aſunder, terminated by an odd one, ending in a very long point, decaying to a whitiſh colour in autumn.

*Red American Aſh*—grows twenty or thirty feet high, having reddiſh ſhoots, large light green leaves, of about three pair of diſtinctly ſawed lobes, terminated by an odd one, five or ſix inches long, and three broad, decaying to a reddiſh hue in autumn.

*Calabrian Manna Aſh*—grows twenty feet high, leaves compoſed of four or five pair of lobes and an odd one; and ſmall greeniſh flowers: from the exſudation of the leaves is collected the manna of the ſhops.

[3]FRAXINUS *Ornus.*

*Flowering Aſh.—Varieties* of this are;

*Virginia flowering Aſh*—grows twenty or thirty feet high, leaves compoſed of three or four pair of ſawed lobes far aſunder, terminated by an odd one; and large looſe bunches of white flowers, at the end of all the branches, furniſhed with petals.

*Dwarf flowering Aſh*—grows twelve or fifteen feet high, ſmalliſh dark green leaves of three or four pair of ſawed lobes and an odd one, and ſmall bunches of flowers furniſhed with petals.

All theſe three ſpecies and varieties are very hardy deciduous trees, the firſt ſort grows common in hedges and woods all over England, but all the others are principally of American growth; all the ſorts flower in April and May, of which none but the *Fraxinus ornus* make any appearance, the others being ſmall, apetalous, and greeniſh; the flowering aſh however, is very ornamental in bloſſom, the bunches being large, and terminate almoſt every branch, appearing extremely conſpicuous; none however but the common aſh produce ſeed in this country, which ripen in great abundance in autumn; but thoſe of all the others are often procured from America by the ſeedſmen, which, as well as the common ſort, grow freely here in any common earth.

The common ſort is generally conſidered as a foreſt or timber-tree, and as ſuch is very valuable, the timber being excellent for many uſeful purpoſes; particularly for almoſt all ſorts of huſbandry implements, ploughs, harrows,

rows, waggons, carts, axle-trees, wheel-fellies, &c. and the poles of the underwood are proper for hoops, hop-poles, and many other uſes; and as the trees grow freely upon almoſt any ſoil, and of quick growth, they may be cultivated to great advantage, ſome to cut every ſeven, ten, or fifteen years for poles, others left to grow for timber; the lop-pings are excellent fuel, and burn well, green or dry, ſo that old pollards, for the purpoſe of lopping at proper intervals of time, will be very profitable.

But the other two ſpecies and varieties are eſteemed principally to aſſiſt in forming va-riety in ornamental plantations, but the flow-ering kinds having the greateſt merit for or-nament, ſhould be introduced in the moſt conſpicuous parts of view.

*Propagation of all the Sorts.*

All the ſorts may be raiſed plentifully from ſeed, which the common ſort furniſh in abundance; but the other ſorts rarely furniſh-ing any here, are procured from abroad, or when their ſeeds cannot be obtained, they are propagated by budding upon ſtocks of the common aſh.

By ſeed.—The common ſort ſhould be ſown in autumn, ſoon after they are ripe, and thoſe of the others as ſoon as they can be obtained, which commonly arrive early in ſpring, and the ſooner the better; prepare for all the ſorts beds of common earth four feet wide, ſow the ſeeds evenly on the ſurface, and cover them an inch deep, ſome of the plants will come up the ſpring following, and many not till the ſecond ſpring: when they are a year or two old, prick them out into nurſery rows, two feet aſunder, and one foot in the lines, and here to remain till they are four, five, or ſix feet high or more, then tranſplant them where they are to remain.

By Budding and Grafting.—This is often practiſed in default of ſeeds, to propagate the ſecond and third ſpecies and varieties, as alſo to continue the variegated kinds, working all of them upon ſtocks of the common aſh, at the uſual ſeaſon of budding and grafting.

FRITILLARIA, Fritillary, including alſo the *Corona Imperialis* and Perſian Lily.

This genus furniſhes a great variety of bul-bous-rooted flowery perennials, proper to adorn the compartments of the pleaſure-gar-den, producing annual ſtalks from about one foot to a yard or more high, terminated by large, bell-ſhaped, liliaceous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, is compoſed of ſix oblong petals, forming a bell-ſhape, ſpreading broad at the baſe. STA-MINA, ſix filaments, and erect four cornered antheræ. PISTILLUM, an oblong three cor-nered, germen, ſimple ſtyle, and triple ſtig-ma. PERICARPIUM, an oblong, trilobate, trilocular capſule, and numerous flat ſeeds.

The ſpecies are;

[1]FRITILLARIA *Meleagris.*

*(Meleagris) or alternate-leafed Fritillary.*] Fritillary, with a depreſſed, fleſhy, bulbous root, an erect flower-ſtalk a foot or fifteen inches high, garniſhed with long narrow leaves placed alternate, and the top termi-nated by one or more large bell-ſhaped flow-ers hanging downwards, of different proper-ties in the varieties.—Some finely chequered in regular ſquares, others of plain colours, as deſcribed below.

[2]FRITILLARIA *Pyrenaica.*

*Pyrenean, oppoſite-leafed Fritillary.*] Fritil-lary with a double, fleſhy, bulbous root, an upright flower-ſtalk twelve or fifteen inches high; garniſhed with long narrow leaves by pairs oppoſite, and the top terminated by two or more large bell-ſhaped flowers hanging downward, of different colours and proper-ties in the varieties.

*Varieties* of the above two ſpecies are—com-mon chequered Fritillary, of which there are ſeveral varieties curiouſly chequered with purple, white, and other colours—dark pur-ple, yellow ſpotted Fritillary—yellow flower-ing—great yellow flowering—variegated yel-low flowered—white flowered—black flowered—with red flowers—red ſpotted flowers—large double-flowering—ſpotted flowered, dif-ferent varieties—umbelliferous flowering—ſpiked flowering—with narrow leaves—broad leaves. All theſe varieties have great merit in the diverſity of their large bell-ſhaped pendu-lous flowers, and thoſe of the chequered kinds have particular ſingularity, being finely chequered in regular ſquares in a very curious manner, flowering principally in the latter end of March, in April, and ſome part of May, ſome late ſorts alſo in June; all of them are ſucceeded by plenty of ſeed in au-tumn.

[3]FRITILLARIA *Perſica.*

*Perſian Fritillary*, commonly called *Perſian Lily.*]—Varieties of this are.

*Tall Perſian Lily.*—Hath a round, whitiſh, bulbous root, an upright firm ſtalk a yard

high, closely garnished with long, narrow, obliquely-waved leaves, and the top terminated by a large pyramidal spike of deep purple flowers spreading wide at their brims.

*Dwarf Persian Lily.*—Produces an erect stalk a foot and half high, small leaves, and somewhat branching spike of deep purple flowers.

4 FRITILLARIA *Imperialis.*

*Imperial Fritillary, commonly called Crown-Imperial (Corona Imperialis)* Fritillary with a very large, round, scaly, bulbous, yellow root, an upright, thick, succulent stalk, three or four feet high, garnished with long narrow leaves; and crowned by a vast surrounding cluster of large, bell-shaped, pendulous flowers, these surmounted by a large crown of leaves; flowering in different colours and properties in the varieties.

The root of this species and varieties is composed of numerous, thick, succulent scales, and is remarkable for imparting a very disagreeable rank odour.

*Varieties of this are*; crown imperial with dusky red flowers—with bright red flowers—late red-flowering—double red flowers—golden yellow flowers—pale yellow flowers—yellow striped flowers—double yellow flowers—doubly-crowned, or crown upon crown, having two tier of flowers one above another—triply-crowned, having three tier of flowers—with gold-striped leaves—and with silver-striped leaves. All these varieties are fine majestic plants, of three or four feet stature, making a singularly grand appearance with their large noble crown of flowers, &c and greatly ornament our gardens so early as April and May; all of them so hardy, of easy culture, and encrease so plentifully by off-sets from the roots, that they might be obtained in abundance in every garden.

The flowers of all the four species of *Fritillaria*, and their varieties, have universally a campanulate, hexapetalous corolla, of the liliaceous kind, all remarkable for their pendulous or hanging position; those of the crown imperial considerably the largest, but all of them form a fine variety in the flower-garden.

All the species and respective varieties are very hardy, bulbous-rooted perennials, the roots of great duration, but the flower-stalks are renewed annually in spring; which in the different sorts flower in March, April, May, and June, when, and in July, they ripen seeds, and the stalks then assume a state of decay, the bulbs become inactive for that season, and ripe for removal, if necessary, either for the purpose of encrease by off-sets, or for transplantation into fresh digged earth, both of which operations may be proper every second or third year, for in that time they will have encreased exceedingly by off-sets into large bunches, and should be divided, and that being planted again in fresh-dug soil, will greatly improve their future bloom.

They all form a fine variety in the principal borders, the two common Fritillary kinds and their varieties shew to best advantage when disposed in three or four roots together, in small patches towards the front of the borders, that is, if they are placed in assemblage with other flowers. The Persian Fritillary or Lily should be stationed rather more backward in the border, and the crown imperials should occupy the middle range behind both these, as being of larger growth, and should always be placed singly, and two or three yards distance in the line; or if you plant the bulbs in beds by themselves, set the Fritillary and Persian-lily kinds in rows a foot asunder, and the same distance in each row, and three or four inches deep; and the crown imperials a foot and half distance each way, and four or five inches in depth.

The season for planting or transplanting all these bulbs is, when thir flower-stalks are decayed in July or beginning of August, tho' the bulbs taken up at that time, may be kept out of the ground two or three months, if necessary, by being laid in dry sand; but the Fritillary and Persian-lily are rather more impatient out of the earth than the crown imperial, and therefore should always be put in again as soon as possible.

Observe, it is always proper to remove all these bulbs every second or third year, to separate the off-sets, and replant the whole in fresh-dug ground. See their *Propagation.*

*Propagation of all the Sorts.*

The more general mode of propagation of all these plants is by off-sets, which they all furnish abundantly from the sides of their roots, and which may be separated every second or third year; the proper time is, when their flower-stalks decay as aforesaid, taking the whole cluster of roots out of the earth, and separate them into distinct roots, planting the smaller off-sets by themselves in nursery beds, to remain a year or two, to acquire a flowering state; and the larger roots, plant where

where they are deſigned to remain for flowering.

They are alſo propagated by ſeed; but this is principally practiſed to gain new varieties, and the proceſs is tedious; the Fritillary and Perſian-lily will be three years, and the crown imperial ſometimes ſix or ſeven before they flower in perfection.

The ſeed are to be ſown in boxes of light earth in Auguſt or September, covering them with earth a quarter of an inch deep, managing them nearly as directed for *colchicums*, tulips, &c. which ſee.

FRUIT-TREES, comprehending ſuch as produce eatable fruit, either for the deſert or culinary uſes.

There are about twelve genera of Fruit-trees and fruit-bearing ſhrubs and ſhrubby plants that ripen their fruit perfectly in this country, each genus compriſing ſeveral ſpecies, and each ſpecies numerous varieties, all of which are exhibited in their reſpective genera; ſo in this place we ſhall only give a liſt of each genus and its principal ſpecies, to ſhew at one view the genus in which each ſpecies is placed according to botanic arrangement.

AMYGDALUS, *Almond-tree*—three ſpecies, the almond, peach, and nectarine; of each of which are many varieties, eſpecially of the peach and nectarine. See AMYGDALUS.

CORYLUS, *the Hazel*, or *Hazel-nut tree*—one ſpecies compriſing the common hazel-nut of the woods—filbert-tree—Barcelona or Spaniſh nut—cob-nut, &c. See CORYLUS.

FAGUS, *Beech-tree*—compriſing the *Fagus Caſtanea* or cheſtnut-tree.

FICUS, *the Fig-tree*—one ſpecies comprehending numerous varieties. See FICUS.

JUGLANS, *Walnut-tree*—one ſpecies of the common walnut, compriſing ſeveral varieties. See JUGLANS.

MESPILUS, *Medlar* — compriſing three principal ſorts. See MESPILUS.

MORUS, *Mulberry tree* — includes three principal ſorts. See MORUS.

PRUNUS, *Plum tree*—includes three principal ſpecies—the plum-tree—apricot—and cherry-tree, each compriſing many varieties; comprehends alſo, the bullace-tree, and the ſloe. See PRUNUS.

PYRUS, *Pear-tree*—compriſes three ſpecies—the pear—apple—and quince, each having many varieties; particularly the pear and apple, whoſe varieties are without end. See PYRUS.

RIBES, *Currant tree*; and *Ribes Groſſularia*, the gooſeberry-buſh; each of which comprehenſive in many eminent varieties. See RIBES.

RUBUS IDÆUS, *Raſberry*—one ſpecies compriſing three or four principal varieties. See RUBUS.

VITIS, *the Vine*—one ſpecies comprehenſive in numerous elegant varieties. See VITIS.

Each of the above genera of fruit-trees, &c. are exhibited in their proper place, and under each are arranged its principal ſpecies, with that of the varieties of each reſpective ſpecies, with their proper names, deſcription, propagation, and general culture.

FUMARIA, Fumatory.

It furniſhes ſome low, tuberous, and bulbous-rooted, flowery perennials, for the flower-garden; producing annual ſtalks ſix or eight inches high, terminated by ſhort ſpikes of ringent flowers.

Claſs and order, *Diadelphia Hexandria*.

*Characters.*] CALIX, two ſmall deciduous leaves. COROLLA, is tubular and ringent, having the lips plane, obtuſe, emarginated and reflexed, having a nectarium at their baſe, and the chops of the corolla four-cornered. STAMINA, ſix equal, broad filaments, each having three antheræ. PISTILLUM, an oblong germen ſhort ſtyle, and an orbicular compreſſed ſtigma. PERICARPIUM, a ſhort unilocular pod and roundiſh ſeeds.

The principal ſpecies are;

[1]FUMARIA BULBOSA.

*Bulbous-rooted Fumatory.*—Varieties of this are.

*Hollow bulbous Fumatory (Cava).*—Having a large fleſhy root, hollow in the middle, crowned by branching leaves, dividing into many ſmall parts, and upright ſtalks ſix inches high, adorned with leaves, and terminated by ſpikes of reddiſh-purple flowers, in April.

*Solid bulbous Fumatory (Solida).*—Having a large, round, ſolid, yellow root; leaves like the former, and ſtalks four or five inches high, adorned with leaves, and terminated by ſpikes of purple flowers, in April.

[2]FUMARIA *Cucullaris.*

*Tuberous-rooted, forked-flowered Fumatory.*] Fumaria, with a ſmall, round, ſcaly root, crowned by leaves divided into three principal parts, each dividing into many ſmaller; upright leafleſs ſtalks, eight or nine inches high, terminated by a looſe ſpike of dull white flowers forked at their baſe; flowering in May.

[3]FUMARIA *Capnoides.*

*Capnoides, or branching ever-green Fumatory.*] Fumaria with a fibrous root, ſending out many ſlender tufty ſtalks, branching eight or nine inches high; finely divided ever-green leaves, and all the branches terminated by looſe pannicles of bright yellow flowers moſt part of ſummer.

*Variety.*] With a whitiſh flower.

[4]FUMARIA *Sempervirens.*

*Ever green podded annual Fumatory*, or *Capnoides.*] Fumaria, with an upright ſtalk branching a foot and half high, garniſhed with branchy finely-divided leaves, and all the branches terminated by looſe ſpikes of pale-purple flowers moſt part of ſummer, ſucceeded by narrow paniculated pods.

The flowers of all theſe plants are of the ringent or gaping kind, are ſmall, but form a pretty variety.

All theſe plants may be employed to adorn the borders of the pleaſure-gardens, placing them in ſmall patches towards the fronts of the borders, where they will appear very ornamental.

The third and fourth ſpecies are alſo proper to diſpoſe on the ſides of rock work, grottos, artificial ruins, &c.

*Their Propagation.*

The two firſt ſpecies and varieties are propagated by off-ſets from their roots, in the manner as other bulbous plants, when their leaves decay any time from May till Auguſt, which may be performed every two or three years, or according as they multiply.

The third and fourth ſpecies are eaſily raiſed in abundance from ſeed, ſown ſoon after they ripen, or in ſpring, ſowing them where they are to remain, or for tranſplanting.

---

# G.

GALANTHUS, Snow-drop.

It conſiſts of one low bulbous-rooted flowery perennial for the flower-borders, riſing but a few inches high, adorned at top with ſmall tripetalous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, an oblong ſpatha opening ſide-ways. COROLLA, three oblong concave ſpreading petals, and in the bottom, a three-leafed nectarium. STAMINA, ſix ſhort filaments, and oblong pointed connivent antheræ. PISTILLUM, an oval germen under the corolla, ſlender ſtyle, and ſimple ſtigma. PERICARPIUM, a three-cornered trilocular capſule, and numerous roundiſh ſeeds.

There is but one ſpecies, viz.

GALANTHUS *Nivalis.*

*Snow drop.*] Galanthus with a ſmall, tunicated bulbous root, crowned with ſeveral long, narrow, blueiſh green leaves, and amidſt them ſmall angular-naked flower-ſtalks, four or five inches high, terminated by a ſpatha, each protruding one ſmall ſnow-white flower drooping downward.

*Varieties.*—Common ſingle-flowered ſnow-drop—ſemi-double ſnow-drop—double ſnow-drop.

Theſe are delightful little plants, conſidering the early appearance of their ſnow-white flowers, adorning our gardens often in January and February, when ſcarce any other flower is to be ſeen, and frequently burſting forth when the ground is covered with ſnow, continuing very often till the beginning of March, and make a very ornamental appearance, eſpecially when diſpoſed in cluſters towards the fronts of borders, &c.

The ſingle ſort comes firſt into bloom, then the ſemi-double, and after that the double.

They ſhould be employed to adorn the fronts of flower-borders, the edges of wilderneſs plantations, the borders of wood-walks, and the fronts of ſhrubbery-clumps, &c. for they will ſucceed any where, and multiply exceedingly by off-ſets from the roots.

They effect conſiderably the beſt appearance when diſpoſed in bunches of ſeveral roots together, placing ſome near the edge of the borders, other bunches a foot or more back, in which order they will form variety more eligibly than in ſtraight rows; or when diſpoſed ſingly, or by way of edgings to borders, as ſometimes practiſed, in which they cut a ſtraggling appearance at firſt.

The

The roots ſhould therefore be planted five or ſix together at leaſt in a cluſter, placing them two or three inches deep, and permit them to remain undiſturbed four or five years to encreaſe into large bunches, they will then form the beſt appearance.

Their propagation is by off-ſets of the roots, the beſt ſeaſon for which is June or July, though, they being ſo hardy, it may be done at almoſt any time after the bloom; but I would prefer ſummer for that work, when their leaves decay, and may either be planted directly, or kept out of the ground till October or November; but do not however retain them longer out of the ground than December, otherwiſe they will flower weak the firſt year. See BULBUS.

GARDENS. Gardens and plantations are grand, ornamental, and oeconomical improvements to a country ſeat and eſtates in general, and may be divided into the following principal diſtricts: The pleaſure-garden—kitchen-garden—orchard—nurſery—and plantations. For a proper deſcription of each, ſee PLEASURE-GARDEN, KITCHEN GARDEN, &c.

GARDENIA, Cape Jaſmine.

There is but one ſpecies, a ſhrubby, very floriferous ever-green, for the green-houſe, and hot-houſe.

Claſs and order, *Pentandria Monogynia*

*Characters.*] CALIX, is monophylous, quinquangular, five-parted and permanent.—COROLLA, a ſalver-ſhaped petal, with a cylendric tube, a plane limb deeply divided into five oval ſegments. STAMINA, no filaments, but five narrow antheræ. PISTILLUM, a germen under the corolla, ſlender ſtyle, and bilobed oval ſtigma. PERICARPIUM, a bilobed berry, and many ſeeds.

The ſpecies is;

GARDENIA *florida.*

*Gardenia, or flowery Cape Jaſmine.*] Gardenia with a woody ſtem, branching in pairs ſeveral feet high, ſpear-ſhaped, entire, ſhining green leaves, four or five inches long, and half as broad, growing by pairs oppoſite; and at the ſides and ends of the branches large cloſe-ſitting flowers, of great fragrance.

The flowers of this ſhrub, although in their characteriſtic ſtate reckoned monopetalous, yet they are often ſemi-double, having two or three ſeries of petals, and often as large as a middling roſe.

This plant is a native of the Cape of Good Hope, but will live here in the full air in ſummer, and in a green-houſe in winter, but flowers beſt in the hot-houſe.

It muſt always be kept in pots of light rich earth.

It is eaſily propagated by layers and cuttings. Lay down ſome young ſhoots in ſpring, in the earth of the pots, they will readily ſtrike root: and cuttings of the ſhoots planted in pots in ſpring or ſummer, and plunged in a bark-bed, or any hot-bed under glaſſes, they will be well rooted in two or three months, when they ſhould be planted in ſeparate pots.

GENISTA, Broom.

This genus retains low, ſhrubby, deciduous, and ever-green plants for the pleaſure-ground and green-houſe, growing from two to ſix or ſeven feet high, adorned with ſmall ſimple leaves, and papilionaceous yellow flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous, tubulous, and bilabiated. COROLLA, is papilionaceous; the vexillum, oval, acute, and wholly reflexed; the wings oblong, ſhort, and looſe; and the keel long and erect. STAMINA, ten diadelphous filaments, and ſimple antheræ. PISTILLUM, an oblong germen, an aſcending ſtyle, and acute involute ſtigma. PERICARPIUM, a roundiſh, bivalvate, unilocular pod, and kidney-ſhaped ſeed.

*Hardy Kinds.*

[1]GENISTA *Sagittalis.*

*Sagittated* or *Arrow-ſhaped, Jointed-Broom.*] Geniſta, with trailing, two-edged, green, ſhrubby ſtalks, dividing into many trailing, flat-jointed branches, garniſhed with ſmall oval-lanceolate leaves, ſingly at each joint, and cloſe ſpikes of yellow flowers at the ends of the branches.

[2]GENISTA *Tinctoria.*

*Dyer's Broom.*] Geniſta, with upright, ſhrubby ſtalks, branching erectly two or three feet high, having taper-ſtriated branches, garniſhed with ſpear-ſhaped, alternate leaves, and from the ſides and ends of the branches numerous ſmall yellow flowers.

*Variety.*—Dyer's-broom with ſpreading branches.

The name *Tinctoria*, or dyer's-broom, to this ſpecies is derived from its uſe in dying; it grows naturally in ſeveral parts of Britain, &c.

[3]GENISTA,

[3]GENISTA, *Anglica.*

*Engliſh Geniſta*, or *Dwarf Engliſh Broom*, or *Petty Whin.*] Geniſta, with ſhrubby ſtalks branching two or three feet high, armed with long ſingle ſpines below, and garniſhed with ſmall ſpear-ſhaped alternate leaves, and cluſters of yellow flowers at the ends of the branches.

This ſpecies grows wild on heaths and other barren places in many parts of England, but is often admitted into gardens for variety.

[4]GENISTA, *Tridentata.*

*Tridented-leafed Portugal Broom.*] Geniſta with upright ſhrubby ſtalks, dividing into many three-cornered branches, riſing three or four feet high, garniſhed with three-pointed leaves, and large yellow flowers, ſingly from the ſides and ends of the branches.

*Variety.* — Low narrow leafed Portugal Broom.

[5]GENISTA, *Candicans.*

*Upright Montpelier Geniſta*, or *Cytiſus of Montpelier.*] Geniſta, with an upright ſhrubby ſtriated ſtem, branching four or five feet high; garniſhed with trifoliate-leaves, hairy underneath, and bright yellow flowers from the ſides of the branches.

*Green-houſe Kinds.*

[6]GENISTA *Canarienſis.*

*Canary Broom*, or *Ever-green Cytiſus, from the Canary Iſlands.*] Geniſta with upright woody flexible ſtalks, branching ſix or eight feet high, into many angular branches, garniſhed with trifoliate, hairy, ever-green leaves, and ſpikes of bright yellow flowers from the ends of the branches.

*Variety* —With white flowers.

The flowers of all theſe ſpecies of *Geniſta*, are of the papilionaceous or butterfly kind, having each four petals; the ſtandard, two wings, and the keel. See the *Characters.*

They flower principally in May and June, and furniſh plenty of ſeeds in autumn.

Of the above ſpecies, the firſt five are hardy deciduous ſhrubby plants for the ſhrubbery; and the ſixth, a tender ever-green for the green-houſe; they all poſſeſs merit as flowery plants, being very floriferous in May and June, and as to the hardy ſorts, they are choice furniture for the fronts of the ſhrubbery-clumps, contiguous to the principal lawns and walks; and the ſixth is a beautiful plant for the green houſe collection, which muſt always be retained in pots for moving to the green houſe in winter.

*Propagation, &c.*

All the hardy ſorts are eaſily raiſed from ſeed in a bed of common earth in autumn, i. e. September, October, or November, covering them with earth near an inch deep; they will riſe in ſpring, and in ſpring following: when the plants are a year old, tranſplant them in nurſery-rows, or if ſome are planted at once where they to remain, they will ſucceed better, becauſe, having long tough roots, they do not thrive well by removal when old; the green-houſe ſort may alſo be raiſed abundantly by ſeed in ſpring, by aid of a moderate hot-bed, ſowing the ſeed in pots, and plunge them in the hot-bed: when the plants are three or four inches high, prick them into ſeparate ſmall pots, and manage them as other green-houſe kinds.

GENTIANA, Gentian, and *Gentianella.*

The plants are principally hardy, herbaceous perennials, of the flowery and medical kind, of different growths, from three or four inches to three or four feet ſtature, ornamented with oblong, ſimple leaves, and largiſh monopetalous, tubular, four or five-parted flowers.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, is oblong, quinquefid and permanent. COROLLA, is monopetalous, tubular at the baſe, and four or five-parted at the top. STAMINA, five ſhort filaments, and ſimple antheræ. PISTILLUM, a cylindric germen, no ſtyle, the germen crowned by two oval ſtigmas. PERICARPIUM, an oblong bivalvate, unilocular capſule, and numerous ſeeds.

The principal ſpecies are;

[1]GENTIANA, *Acaulis.*

*Short-ſtalked blue Gentian, commonly called Gentianella.*] Gentian, with thick fibrey roots, crowned by oblong leaves, many flower-ſtalks but two or three inches high, exceeded by the corolla, garniſhed with ſpear-ſhaped, cloſe-ſitting, oppoſite leaves; and at top, large, bell-ſhaped, five-parted, erect, azure-blue flowers, of great beauty, appearing in May.

[2]GENTIANA, *Aſclepiadea.*

*Aſclepias-leafed Gentian.*] Gentiana, with thick fibery roots, crowned by oval-lanceolate leaves, flower-ſtalks a foot high, garniſhed with oval, ſpear-ſhaped amplexicaule, oppoſite leaves, and from each ſide largiſh, bell-ſhaped, blue flowers by pairs, appearing in June and July.

[3]GENTIANA,

[3]GENTIANA, *Cruciata.*

*Croſs-wort Gentian.*] Gentiana, with creeping fibrey roots, weak flower-ſtalks ſix inches long, garniſhed with ſpear-ſhaped, oppoſite leaves by pairs, each pair croſſing the other, and four-parted, light blue flowers, in whorls below, and in cluſters at top, appearing in May.

[4]GENTIANA *Lutea.*

*Great Yellow Gentian*] Gentiana, with thick, carroty-yellow, roots, crowned by large, oval, oblong-pointed, veined, ſtiff leaves; ſtrong flower-ſtalks three or four feet high, garniſhed with ſmaller, oppoſite, amplexicaule leaves; and wheel-ſhaped, deeply, five-parted, yellow flowers, in whorls at the upper parts, appearing very ornamental in July and Auguſt: it is alſo a valuable medical plant, and the root is the uſeful part.

The flowers or corolla of all theſe plants is of one tubular petal, more or leſs divided into four or five parts. See the *Characters.*

The plants are all perennial in root, but annual in ſtalk, which riſe in ſpring, flower in ſummer, produce abundance of ſeed in autumn, and ſoon after die to the ground.

All the ſpecies, conſidered as flowery plants are very ornamental, the low ſorts are elegant furniture for the fronts of borders and other flower compartments, and the large yellow kind ſhould be ſtationed more backward, among the taller claſs of plants, where it will exhibit a noble appearance; and as all the ſorts proſper in any common ſoil, affording plenty of ſeed for propagation, ſeveral of them alſo encreaſe by off-ſets, they may be obtained plentifully in every garden.

All the ſorts are eaſily raiſed from ſeed in the full ground, the firſt three ſorts alſo by off ſets from the roots.

By ſeed.—Sow the ſeed in autumn, ſoon after they are ripe, or early in ſpring, in a bed or border of light rich ground, either by broad-caſt on the ſurface, and rake it in lightly, or in ſhallow flat drills ſix inches aſunder, covering it near half an inch deep; the plants will riſe in April or May, give moderate watering in dry weather, and clear out weeds; and in ſummer, and towards autumn, prick out a quantity of the beſt into beds, in rows ſix inches aſunder, where let them remain a year to gather ſtrength, then in autumn or ſpring tranſplant them into the places where they are to remain to flower.

By roots.—The firſt three ſpecies encreaſe by off-ſets of the roots in tolerable plenty, and autumn, winter, or ſpring is the time to ſeparate or divide them, and the ſlips or off-ſets, if ſmall, may either be planted in nurſery-beds for a year, or, if not divided too ſmall, may place them at once in the flower compartments.

GENUS, a fraternity, race, or kind; being an aſſemblage of different ſpecies of plants, reſembling each other in the flower and fruit, or parts of fructification.

The characteriſtical mark of every Genus is the whole of the flower or fructification, and all plants agreeing exactly therein, are ſpecies of the ſame family or Genus; a Genus therefore, may in ſome meaſure be compared to a family, all the relations of which bear the ſame ſurname, although every individual is diſtinguiſhed by a particular ſpecific name; and that by arranging under one generic name, a collection of different ſpecies of plants, which although often ultimately different in their general growth, external port or habit, yet are all found invariably to poſſeſs certain relations in the generical characters of their eſſential parts, the fructification or flower and fruit, that declare them all plants of the ſame family or Genus.

A Genus of plants therefore, however numerous the ſpecies, and different in their general growth, external habit, and duration, are ſuch as agree in all the parts of the flower, which being the only generical characters, a principle now univerſally eſtabliſhed by the Linnæan botany, in no caſe to be departed from. See CHARACTERS. For the *characters* of every Genera or Genus contains a deſcription of each particular part of the flower, as the *Calix*, *Corolla*, *Stamina*, *Piſtillum*, *Pericarpium*, *Semen*, and *Receptaculum*; which being the ſeven parts of fructification, and the moſt eſſential and invariable parts of plants, and conſequently the only parts that can determine the generical characters; and the ſtriking ſingular mark of each of the above parts of the flower, muſt run through all the ſpecies of each reſpective Genus, according to the deſcriptive *characters* in the beginning of every Genus throughout this work; whereby, as afore-mentioned, every ſuch aſſemblage of plants, however few or numerous, ſo agreeing in their fructification, form a Genus.

By arranging every aſſemblage of plants agreeing in their fructification, under one denomination or generical name, renders botany more ſimple and eaſy, which by the ancients was but little underſtood; as with them, al-

moſt every ſpecies was a Genus, and they had no conception of giving one common or general name to a number of plants, which although agreeing in their flower, they could, not diſcover poſſeſſed any thing in common; for the minute parts of the fructification which lay the foundation of our preſent ſyſtems, were then but little known, and as little attended to, as in fact the root: port or external habit of plants, their duration, mode, and times of flowering, and their uſes, both medicinal and oeconomical, formerly furniſhed the ſole characteriſtical diſtinction, all of which however, are vague and indeterminate; but as the fructification is conſtantly the ſame in every reſpective Genera, nothing but theſe parts can with certainty be employed in determining each ſeparate Genus.

Plants and trees of the ſame Genus generally poſſeſs like medicinal powers. As for example, garlick, onion, and leek, belong to the Genus *allium*; cinnamon, camphire, and ſaſſafras belong to the Genus *laurus*; ſouthernwood, wormwood, mugwort, &c. belong to the Genus *artemiſia*.

Trees which belong to the ſame Genus, will alſo all take by grafting or budding upon each other: as for inſtance; pear, apple, and quince, being all of the Genus *pyrus*, take freely upon one another; plum, apricot, cherry, and bird-cherry, &c. being all of the Genus *prunus* alſo, grow upon ſtocks of each other; almond, peach, and nectarine belong to the Genus *amygdalus*, and grow upon one another; currant and gooſeberry belong to the Genus *ribes*, and all the varieties will grow upon each other; as will alſo moſt other trees of the ſame Genus.

The number of known Genera is upwards of twelve hundred, and above twenty-thouſand different ſpecies, beſides varieties; all of which are found growing in their natural ſtate of wildneſs in ſome part of the globe or other, and moſt of them may be naturalized in our gardens, ſome in the open ground, others in the green-houſe and ſtove; but the gardener is not to be intimidated at the ſight of that great number, as if the care of ſo great a family was to fall to his lot; ſince our real valuable cultivated ſpecies fall vaſtly ſhort of that number, yet ſufficient to furniſh our gardens moſt amply, both for oeconomical and ornamental purpoſes.

GERANIUM, Crane's-bill, but commonly called *Geranium*.

It comprizes herbaceous and ſhrubby plants for the pleaſure-ground and green-houſe, obtaining different ſtatures from one or two, to ſix or eight feet high, adorned with broad ſimple leaves, in ſome roundiſh, others heart-ſhaped and oval, ſome intire, and ſome divided, and cluſters of ſmall pentapetalous flowers.

Claſs and order, *Monadelphia Decandria*.

*Characters.*] CALIX, five oval permanent leaves. COROLLA, five oval, or elſe heart-ſhaped, ſpreading petals. STAMINA, ten monadelphous filaments alternately longer, and oblong verſatile antheræ. PISTILLUM, a five-cornered germen, long permanent ſtyle, and five-reflexed ſtigmas. PERICARPIUM, a long fruit, ſhaped like a crane's beak or bill, is quinquelocular, and contains five ſeeds.

There are upwards of fifty ſpecies, and of which the following are the ſorts principally cultivated in the Britiſh gardens.

*Hardy herbaceous kinds.*

[1]GERANIUM, *Pratenſe*.

*Meadow Crow-foot Geranium.*] Geranium with many branchy ſtalks, two or three feet high, garniſhed with divided, target-ſhaped leaves of ſix or ſeven lobes, cut into many wing-like acute parts; and at the top of the ſtalks large blue flowers, two upon each foot-ſtalk.

*Varieties.*]—With white flowers—variegated flowers.

[2]GERANIUM *Sanguineum*.

*Bloody Geranium.*] Geranium with thick, fleſhy, fibrey roots; weak, branchy ſtalks, a foot or more high, garniſhed with divided leaves of five-trifid lobes; and deep red or purple flowers from the ſide of the branches, one upon each foot-ſtalk.

*Varieties.*]—With erect ſtalks—with deeply jagged leaves—and with variegated flowers.

[3]GERANIUM *Phæum*.

*Black flowered Geranium.*] Geranium, with upright, branchy ſtalks, ten or twelve inches high, divided leaves, of five or ſix laciniated lobes, and the branches terminated by blackiſh purple flowers, two upon each foot-ſtalk.

[4]GERANIUM *Nodoſum*.

*Knotty Geranium.*] Geranium, with jointed, branchy ſtalks, ſix or eight inches high, garniſhed with divided leaves of three ſerrated lobes, thoſe below having foot-ſtalks, the upper ones ſit cloſe, and at the ends of the branches, pale purple flowers by twos upon each foot-ſtalk.

[5]GERANIUM *Macrorhizum*.

*Long-rooted, Sweet-ſmelling Geranium.*] Geranium, with a long thick fleſhy root; branchy ſtalks

ſtalks a foot high, garniſhed with five-lobed, ſmooth leaves, the lobes divided into many ſhort crenated ſegments, and the branches terminated by bunches of purple flowers, two upon each foot-ſtalk, and with inflated or bladder-like cups, and very long ſtyle.

[6]GERANIUM *Striatum.*

*Striated Geranium.*] Geranium with many branchy ſtalks near two feet high, garniſhed with five-lobed leaves below, and three-lobed ones above, and white flowers beautifully ſtriated with purple, two upon each foot-ſtalk.

The above ſix ſpecies are very hardy fibrous perennials, durable in root, but annual in ſtalks, &c. which riſe from the root in ſpring; flower in May, June, and July, producing a great profuſion of flowers, each compoſed of five ſmalliſh ſpreading petals. See the *Characters:* and their numbers renders them very conſpicuous, and are ſucceeded by plenty of ſeed in Auguſt and September, which if permitted to ſcatter on the ground, a crop of young plants will naturally riſe in abundance.

Several of them grow naturally in many parts of England, particularly the firſt, ſecond, third, and fourth ſorts; the others are chiefly of foreign growth.

All the ſorts proſper in any common ſoil of a garden.

They may all be employed as ornamental plants for the embelliſhment of the different compartments of the pleaſure-ground, and to encreaſe the variety of the herbaceous collection; and as to their culture, they require only the common care of keeping clean from weeds, cutting down their decayed ſtalks, and digging between them annually in autumn, or any time in winter or ſpring.

They may all be propagated plentifully by ſeed, and by parting their roots.

By Seed.—Sow it in autumn ſoon after it is ripe, or in ſpring in a ſhady border, and rake it in lightly; when the young plants are about three inches high, prick them out in beds five or ſix inches aſunder, giving occaſional waterings, and in autumn or ſpring after, tranſplant them where they are to remain.

By Parting the Roots.—This may be performed any time from October till March, in open weather; do not divide them into too ſmall ſlips; and may plant them at once where they are to remain.

*Green-houſe Shrubby kinds.*

[7]GERANIUM *Zonale.*

*Zone marked, or Horſe-ſhoe Geranium.*] Geranium with a ſhrubby ſtem, branching ſix or eight feet high, garniſhed with roundiſh heart-ſhaped, indented leaves, marked with a purple zonal circle, going quite round, in form of a horſe-ſhoe; and from the upper parts of the branches, cloſe bunches of reddiſh-purple flowers on very long foot-ſtalks.

*Variety.*]—Zone-marked Geranium, with elegantly variegated leaves, of ſingular beauty.

Both theſe varieties of this ſpecies are the ſorts of *Genarium* the moſt commonly cultivated in our gardens, and are both very floriferous moſt part of ſummer; but the variegated ſort is ſingularly ornamental at all ſeaſons with its variegated white and green leaves.

[8]GERANIUM *Capitatum.*

*Capitated Roſe-ſcented Geranium.*] Geranium, with a ſhrubby ſtalk branching irregularly four or five feet high; roundiſh, unequally trilobated, waved, hairy leaves, ſmelling like dried roſes; and purpliſh-blue flowers in a capitated corymbus at the ends of the branches.

[9]GERANIUM *Fulgidum.*

*Fulgid or flaming red Geranium.*] Geranium with a ſhrubby, fleſhy ſtalk, branching a foot or two high, garniſhed with divided, three-lobed, ſmooth, light-green leaves cut on the edges, having the middle lobe largeſt; and flame-ſcarlet flowers in umbellate cluſters from the ſides of the branches.

[10]GERANIUM *Inquinans.*

*Large Mallow-leafed Scarlet Geranium.*] Geranium with a ſhrubby ſtem, branching erectly ſix or eight feet high, garniſhed with roundiſh kidney-ſhaped, thick, bright green leaves, hoary underneath; and bright ſcarlet flowers on long foot-ſtalks from the ſides of the branches.

[11]GERANIUM *Papilionaceum.*

*Papilionaceous flowered Geranium.*] Geranium with a ſhrubby ſtalk, branching ſix or ſeven feet high; large angular, ſharp-pointed, rough leaves, upon long foot-ſtalks; and papilionaceous-ſhaped, finely variegated flowers, in looſe bunches at the ends of the branches.

[12]GERANIUM *Cucullatum.*

*Cucullated or hood-leafed Geranium.*] Geranium with a ſhrubby ſtalk branching ſix or ſeven feet high; roundiſh, indented nervous leaves, hollow in the middle like a hood; and purpliſh blue flowers, in large looſe bunches at the top of the branches.

*Variety.*]—With angular, hooded leaves.

[13]GERANIUM *Vitifolium.*

*Vine-leafed, Balm-ſcented Geranium.*] Geranium with a ſhrubby ſtalk, branching five or ſix feet high, aſcending, lobated, downy leaves, and pale blue flowers in cloſe bunches, on long foot-ſtalks from the axillas of the branches.

[14]GERANIUM *Gibboſum.*

*Gibbous, or gouty-ſtalked Geranium, with Columbine leaves.*] Geranium with a ſhrubby, fleſhy ſtalk, gibbous, or ſwoln at the joints, branching three or four feet high; doubly pinnatifid, fleſhy, ſmooth, oppoſite leaves; and dark purple flowers at the upper parts of the branches.

[15]GERANIUM *Carnoſum.*

*Carnoſe, or fleſhy-ſtalked Geranium.*] Geranium with a ſhrubby, very thick, fleſhy-jointed ſtalk, branching two or three feet high; pinnatifid, laciniated, tthinly-placed leaves; and whitiſh flowers at the top of the branches.

[16]GERANIUM *Betulinum.*

*Birch-leafed Geranium.*] Geranium with a ſhrubby ſtalk branching four or five feet high, oblong, oval, plane, unequally ſawed leaves, and large reddiſh flowers from the ſides of the branches.

[17]GERANIUM *Peltatum.*

*Peltated, or Shield-leafed Geranium.*] Geranium with ſlender, weak, ſhrubby ſtalks, branching two or three feet long; peltated, divided, fleſhy, ſmooth leaves, of five entire lobes; and purple flowers by fours or fives, from the ſides of the branches.

[18]GERANIUM *Acetoſum.*

*Sorrel-taſted Geranium.*] Geranium with a ſhrubby ſtalk, branching five or ſix feet high; oval, fleſhy, ſmooth leaves, taſting like ſorrel; and bluſh-coloured red-ſtriped flowers, by threes or fours, from the ſides of the branches.

*Variety.*]—With ſcarlet flowers.

All theſe ſhrubby *Geraniums* are beautiful ever-greens, being furniſhed with leaves all the year, and moſt of them very floriferous in ſummer, flowering principally in May, June, and July, though ſeveral of the ſorts continue a ſucceſſion of flowers during moſt of the ſummer months, even often until winter. They are moſtly free ſhooters, and ſome of them ſhoot luxuriantly, eſpecially when potted in rich, loamy earth; and the ſhoots of moſt of them are rather ſomewhat ſucculent, and of an herbaceous nature the firſt ſeaſon of their growth, but become more woody as they advance in age: their leaves are moſtly of an orbicularly roundiſh figure, notwithſtanding thoſe of ſome ſorts are divided into lobes, and are from about two to four inches broad, and moſtly foot-ſtalked: the flowers are quinque-petalous, and ſeparately are rather ſmall, but being generally produced in cluſters, are very conſpicuous and ornamental; and in ſeveral of the ſorts are ſucceeded by ſeeds, which falling in the pots, ſometimes many young plants riſe naturally.

They being all natives originally of Africa, are of tender quality; and in their culture here, muſt always be retained in pots, for moving to the ſhelter of a green-houſe, &c. in winter, for they will not live here in the open air during that ſeaſon: they however only require protection from froſt, and being free-ſhooters, ſhould have as much free air as poſſible in open weather, therefore in winter, when placed in the green-houſe, ſhould always be ſtationed towards the front next the windows.

All the ſorts are beautiful furniture for the green-houſe collection, and thoſe with variegated leaves exhibit a delightful contraſt with all the others; and as all of them may be raiſed abundantly by ſeed and cuttings, in the common ground, they may be obtained plentifully in every garden.

The propagation of all theſe ſhrubby ſorts, may be effected abundantly by ſeed, and by cuttings of their branches, though, as they all grow very freely by cuttings, they are moſt commonly propagated by that method; and both methods of propagation may be effected either in the natural ground, or by aid of hot-beds, to bring them more forward.

By Seed.—In April the ſeed may be ſowed either in a bed of light rich earth a quarter of an inch deep, or in pots or boxes of the ſame ſoil, and the plants will come up in ſix weeks; but to forward their growth as much as poſſible, to be ſtrong before winter, it is more adviſeable to ſow in a hot-bed, that is, in March or April ſow it in pots, and plunge them in any hot-bed under glaſſes, and when the plants are two inches high, prick them into ſeparate pots, which if plunged alſo in a hot-bed, will greatly forward the ſeedlings, giving occaſional waterings, and ſhade till rooted, and in June harden them by degrees to the full air.

By Cuttings.—Theſe may be planted in the full ground any time in May, June, and July; or to have them more forward, may plant ſome in pots in March or April, and plung in a hot-bed; in either caſe take off the

the cuttings with a knife, from about four or five to eight or ten inches long, trimming off the leaves from the body of each cutting; obſerving, if the top is very ſoft and herbaceous, it may be ſhortened down to the firm wood, but when robuſt and firm, leave it intire; they may be planted either in the full ground in a ſhady border if in ſummer, or in pots placed in the ſhade, or as above obſerved, may plant them in pots in March, April, or May, and plunged in a hot-bed; or for want of this, may plant them in pots at the time juſt mentioned, and retain them in the green-houſe till May or June: in either mode of planting, put the cuttings two parts out of three into the ground, give a little water directly, and repeat it occaſionally, and the cuttings will ſoon emit roots at bottom, and ſhoots at top, and be fit to tranſplant into ſeparate pots in two or three months.

But the moſt expeditious way of raiſing them by cuttings, to have ſtrong plants by winter, is to forward them in a hot-bed; planting the cuttings in pots, ſeveral in each; in March, April, or May, as above hinted, plunge them either in a dung hot-bed, or in a bark-bed in the hot-houſe, &c. they will quickly take root, and ſhoot at top, when they ſhould be planted out into ſeparate pots, and in June inure them gradually to the full air, and they will branch out at top and make fine plants by October.

With reſpect to their general culture, obſerve as follows:

They proſper in any light rich earth, but grow the moſt luxuriant in a moderate loamy ſoil; though in a light mold, as they ſhoot moderately, are more profuſe in flowers.

They, as before noticed, muſt always be retained in pots for moving to ſhelter in winter, and into the full air in ſummer; in ſummer therefore, about the middle or latter end of May place them in the open air till October, obſerving to give frequent waterings in dry weather, which, in a very hot dry time, will be requiſite almoſt every day. Towards the latter end of October remove them into the green-houſe to remain until May, placing them rather towards the front next the windows, in order to have as much free air as poſſible, otherwiſe they will be apt to draw up weak, and ſometimes the young ſhoots will mould and root off, eſpecially if they are much crowded. During their reſidence here give moderate watering once a week, or ten, or twelve days, as you ſhall ſee neceſſary, and as the ſpring and warm weather advances, give more in proportion; giving it always in moderation whilſt they remain in the green-houſe, eſpecially the fleſhy or more ſucculent kinds, which are apt to take a mouldineſs, and rot with redundant moiſture, or very damp air at this ſeaſon; and with reſpect to freſh air, they of courſe will have it in common with the other exotics of the ſame department. See GREEN-HOUSE PLANTS. Keep all decayed leaves conſtantly picked off, being neceſſary to the health and beauty of the plants; they being very faſt growers, ſhould be ſhifted every year at leaſt, into larger pots; the proper ſeaſon, April and May, being careful to remove them with the balls of earth about their roots, paring off the outſide matted fibres, and clear off alſo ſome of the old earth all around; and ſo pot them again directly in ſome freſh mould, filling up around the ball, and about an inch in depth over its top, with the ſame new ſoil.

*Green-houſe herbaceous kinds.*

[19]GERANIUM *Alchimilloides.*

*Ladies Mantle-leafed Geranium.*] Geranium with herbaceous trailing ſtalks a foot and half long; roundiſh, palmated, hairy leaves, the edges cut into many parts; and whitiſh flowers in cluſters moſt part of ſummer.

*Varieties.*]—With a dark circle in the middle of the leaves—and with blueiſh flowers.

[20]GERANIUM *Odoratiſſimum.*

*Odoriferous, or Sweet-ſcented Geranium.*] Geranium with an herbaceous, ſhort, fleſhy ſtalk, dividing into ſeveral ſhort branchy-heads, garniſhed with heart-ſhaped, ſoft, downy leaves ſtrongly ſcented, and many ſmall white flowers by fours or fives, appearing moſt part of ſummer.

[21]GERANIUM *Groſſularoides.*

*Gooſeberry-leafed Geranium.*] Geranium, with herbaceous, proſtrate ſtalks, branching a foot and half long; ſmall, roundiſh, heart-ſhaped, crenated leaves; and reddiſh flowers on ſhort foot-ſtalks from the ſides of the branches.

[22]GERANIUM *Triſte.*

*Dark-ſpotted night-ſmelling Geranium.*] Geranium with a thick tuberous root, crowned by pinnatifid, finely divided, proſtrate leaves; and among them ariſe bifid, naked, flower-ſtalks, terminated by bunches of yellowiſh dark-ſpotted flowers, ſmelling ſweet in the evening.

[23]GERANIUM

[23]GERANIUM *Prolificum.*

*Prolific or Variable Geranium.*] Of which there are ſeveral varieties.—With thick tuberous roots, of different ſhapes, crowned with leaves; alſo of various forms in the varieties, and among them, the flower-ſtalks directly from the root, terminated by compound umbels of flowers, which in the different ſorts, are red, crimſon, purple, white, &c.

*Varieties of this are:*

*Pinnated Prolific Geranium.*—Having leaves divided in the pinnated manner, in ſome into oval lobes, others into long narrow parts.

*Auriculated Prolific Geranium.*—Having oblong, and ſometimes three-parted leaves, auriculated or eared at each ſide of the baſe.

*Long-leafed Prolific Geranium.*—Having very long ſpear-ſhaped leaves.

*Fleſhy-leafed Prolific Geranium.*—Having oval haſtated fleſhy leaves.

[24]GERANIUM *Lobatum.*

*Lobated Geranium.*] Geranium with a roundiſh, large, fleſhy root, crowned with lobated, hairy crenated leaves, ſhaped like thoſe of vines; and between them naked, truncated flower-ſtalks a foot high, terminated by umbellate cluſters of red, and in ſome ſorts white flowers.

*Varieties.*]—With pinnatifid leaves—with laciniated leaves.

All theſe tender herbaceous *Geraniums*, being natives of Africa, as obſerved of the ſhrubby kinds, muſt always be kept in pots, to move to ſhelter in winter. They grow freely in any light rich garden earth, and may be preſerved through the winter either in a greenhouſe or garden-frame, under occaſional ſhelter of the glaſs lights.

All the tuberous-rooted kinds are remarkably fine ſcented in the night, hence are denominated *Geranium Noctu olens*, or night-ſmelling Geranium.

They may be propagated by ſeed ſowed in ſpring, in pots of light earth, and placed in a hot bed, as directed for the ſhrubby ſorts; they may alſo be propagated by ſlipping their roots in Auguſt or September, or early in ſpring, which, of the tuberous kind, every ſlip of the tubers having an eye or bud, will readily grow.

GERMEN, the ſeed-bud, i. e. the baſe of the piſtillum, is ſituated in the bottom of the flower, and contains the rudiments of the ſeed, and in progreſs of vegetation ſwells, and becomes the ſeed-veſſel.

The Germen in all plants is ſituated in the bottom of the flower; in ſome however, within the corolla, and in others, under its baſe, and which always ſupports the ſtyle and ſtigma, the female organs of generation, whereby modern botaniſts denominate the ſeed-bud or Germen, the *Ovarium* or *Uterus* of plants, which, after its impregnation by the male duſt of the antheræ or male organ falling upon the ſtigma, it becomes a ſeed-veſſel, gradually ripening to maturity, together with the ſeeds contained therein.

GERMINATIO, the Germination or ſprouting of ſeeds, after being committed to the earth.

Different ſorts of ſeeds are longer or ſhorter in germinating, and riſing according to their nature and heat requiſite for each; ſeveral of the graſſes often riſe in one day; creſſes, muſtard, radiſh, rape, and turnip, in from three to ſix or eight days; cucumber, melon, gourd, cabbage, ſavoy, cauliflower, broccoli, beet, ſpinach, lettuce, purſlane, dill, orach, bean, kidney-bean, pea, &c. in from about three or four, to ten or fifteen days; onion, leek, carrot, parſnip, celery, in from about ten or twelve, to eighteen or twenty days; parſley, from about fifteen or twenty, to forty or fifty days; hawthorn, medlar, and ſeveral other hard, bony ſeed, and nuts, are often two years before they germinate; and ſome of the liliaceous plants never riſe at all; obſerving, that in reſpect to the above obſervations of the germination of ſeed, it is principally to be underſtood of ſeeds ſown in ſpring and ſummer, and the more advanced and warm the ſeaſon, the ſooner may the ſeed be expected to riſe.

Seeds alſo preſerve their germinating property ſhorter or longer according to their kinds; ſome do not retain it ſcarcely a year, others for a ſeries of years; particularly many of the papilionaceous tribe: and it is aſſerted, that the ſenſitive plant retains its germinating faculty for thirty or forty years.

Moſt ſeeds germinate the moſt freely when ſowed in ſpring and ſummer; ſome however require to be ſown in autumn, ſoon after they are ripe, otherwiſe they will not ſprout in leſs than a year or two, which ſorts are always hinted in the courſe of the work, under their reſpective articles.

As air and moiſture are the agents of vegetation, it is for want of air that ſeeds which are buried at a very great depth in the earth, either riſe but indifferently or not at all; they frequently however preſerve their germinating

nating property for many years within the bowels of the earth, and it is not unuſual upon a piece of ground being dug up to a conſiderable depth, to ſee it covered with ſeveral plants, which probably have not been ſeen there in the memory of man. Seeds will alſo retain their vegetative virtue for years in the bottom of wells, ditches, ponds, &c. which when cleaned out, and the mud expoſed to the air, various ſorts of plants have riſen therein, that had not appeared thereabouts for a great number of years, by which circumſtances certain ſpecies of plants regarded as loſt, have been accidentally recovered.

GEUM, Avens, or Herb-bennet.

The plants are hardy, herbaceous perennials for the pleaſure-ground, riſing with annual ſtalks about a foot high, terminated by pentapetalous flowers.

Claſs and Order, *Icoſandria Polygynia.*

*Characters* ] CALIX, is monophyllous, cut into ten ſegments alternately ſmaller. COROLLA, five roundiſh petals, long and narrow toward the baſe. STAMINA, numerous filaments, and broad obtuſe antheræ. PISTILLUM, numerous germina collected into a head, and many long, hairy ſtyles, and ſimple ſtigmas—PERICARPIUM, none, numerous ſeeds ſitting on the oblong receptacle placed on the calix.

The principal ſpecies are;

[1]GEUM *Urbanum.*

*Common Avens or Herb-bennet.*] Geum with thick, fibrey, aromatic roots, crowned by large, lyre ſhaped, rough, ſerrated leaves, and upright, round, hairy ſtalks, a foot high, terminated by largiſh yellow flowers, ſucceeded by globular fruit.

This grows wild in woods and by hedge-ſides in England, &c. the root is uſed in medicine, and the young leaves often as a pot-herb.

[2]GEUM *Rivale.*

*Waternodding-flowered Avens.*] Geum, with a thick, fleſhy, very fibrey root, crowned with large lyrated, hairy leaves, and upright ſtalks ten or twelve inches high, terminated by purple flowers nodding on one ſide.

*Varieties.*]—With red flowers—large yellow flowers.

[3]GEUM *Virginianum.*

*Virginian Avens.*] Geum with upright ſtalks a foot and half high, ternate leaves below, thoſe above ſimple, and the ſtalks terminated by ſmall white flowers.

[4]GEUM *Montanum.*

*Mountain Avens of the Alps.*] Geum with a thick, fleſhy, fibrated, creeping root, crowned with leaves compoſed of ſeveral ſmall irregular lobes, terminated by a broad roundiſh one, and ſlender ſtalks near a foot high, garniſhed with narrow ſharp-pointed leaves, and terminated by erect yellow flowers.

*Variety.*] —Dwarf Alpine Avens, with a large golden flower.

All theſe plants have perennial roots and annual ſtalks, which riſe in ſpring, flower in May and June, and ripen ſeeds in July and Auguſt. The plants are hardy, and ſucceed almoſt any where.

They may be introduced in the pleaſure-ground here and there towards the fronts of the flower and ſhrubbery compartments, to encreaſe the variety.

Their propagation is both by ſeed, and by parting the roots. Sow the ſeed in September in a bed or border, and the plants will riſe in ſpring. By parting the roots, it may be done any time, in open weather, from September till March.

GLADIOLUS, Gladiole, Sword-lily, or Corn-flag.

The plants are tuberous-rooted, herbaceous, flowery perennials, of the liliaceous tribe, for the pleaſure-garden, having ſword-ſhaped leaves, and erect annual ſtalks two feet high, adorned with hexapetalous, lily-like flowers.

Claſs and order, *Triandria Monogynia.*

*Characters.*] CALIX, a ſpatha to each flower. COROLLA, ſix oblong petals united at their baſe, the three upper ones incline to each other, and the under ones ſpread open. STAMINA, three filaments, inſerted into every other petal, and oblong antheræ. PISTILLUM, a germen under the corolla, ſingle ſtyle, and trifid concave ſtigma. PERICARPIUM, an oblong, ventricoſe, trigonal, trilocular capſule, and roundiſh ſeeds.

There is but one hardy ſpecies common to the Engliſh gardens, out of which are many eminent varieties.

GLADIOLUS *Communis.*

*Common Gladiole.*] Gladiolus with a round, compreſſed, tuberous, bulb-like root, ſending up long ſword ſhaped leaves, embracing each other at the baſe, between them an erect flower-ſtalk two or three feet high, the top garniſhed with ſeveral largiſh flowers at a diſtance, of different colours in the varieties, and in ſome ranged all on one ſide of the ſtalk, and in others in two ranges, &c.

*Varieties.*]

*Varieties.*]—Common red Gladiolus, with flowers ranged on one ſide of the ſtalk—purple flowers on one ſide of the ſtalk—white flowers on one ſide of the ſtalk—crimſon flowers on one ſide of the ſtalk—red flowers ranged in a double ſeries—white flowers in a double ſeries—broad-leaſed, tall Gladiole, with large purple flowers—broad leaves, and large crimſon flowers. All of which are varieties of one ſpecies, as the ſeed ſaved from one plant often produces them all. They all flower in the end of May, and in June are very conſpicuous and ornamental, and are ſucceeded by plenty of ſeed in Auguſt, and their ſtalks and leaves decay ſoon after; the flowers are moderately large, each of ſix petals. See the *Characters.*

The plants are very hardy, and will flouriſh almoſt any where, and encreaſe greatly by their roots, eſpecially the common red ſort, ſo as often to become troubleſome.

They are proper furniture for the common flower borders, &c. intermixed with other perennials of ſimilar growth, where they will exhibit a very fine appearance when in flower.

The roots are ſold at the nurſeries and ſeed ſhop, and the time to plant them is September, October, and November. They ſhould be taken up every two or three years at the decay of the leaves, to ſeparate the off-ſets, &c.

All the varieties are propagated plentifully by off ſets from the roots, which they emit in abundance every year like tulips and other bulbs. July and the beginning of Auguſt, when the ſtalks and leaves decay, is the time to take up the roots to ſeparate the off-ſets, or tranſplant the roots from one place to another; though if taken up at the proper time, they may be kept out of the ground till October or November, or longer if neceſſary.

They may alſo be propagated by ſeed. Sow it in autumn in a bed or border of light earth, the plants will come up in the ſpring, and when their leaves decay in ſummer, tranſplant them into nurſery-beds to remain a year or two, till of due ſize to flower; then tranſplant them where they are to remain.

GLEDITSIA, Triple-thorned Acacia.

There is but one ſpecies, a large deciduous tree for ornamental plantations, adorned with beautiful pinnated foliage, and amentaceous male and hermaphrodite flowers on the ſame plant, and females on ſeparate trees.

Claſs and order, *Polygamia Dioecia.*

*Characters.*] CALIX, male flowers collected in a long compact cylindric katkin, terminated by the hermaphrodites, each having a three-leafed cup, and female flowers on ſeparate plants, having a five-parted calix. COROLLA, three roundiſh petals in the males and hermaphrodites, and five long acute ones to the females. STAMINA, ſix filaments and oblong antheræ. PISTILLUM, a broad germen longer than the corolla, ſhort reflexed ſtyle, and thick ſtigma. PERICARPIUM, a large flat pod, having tranſverſe partitions, each diviſion replete with pulp, and one hard round ſeed.

The ſpecies is;

GLEDITSIA *Triacanthos.*

*Triple-thorned Acacia.*] Gleditſia, with an upright trunk, riſing thirty or forty feet high, branching out regularly, and having the ſtem and branches armed with many long triple thorns, and cloſely garniſhed with doubly pinnated leaves, each leaf conſiſting often of near two hundred ſmaller leaves or foliola; and amentaceous greeniſh flowers from the ſides of the branches, ſucceeded by broad ſeed-pods near a foot and half long.

*Variety.* With fewer thorns, ſmaller leaves, and oval pods.

Theſe trees have ſingular beauty in ſummer, when cloathed with their large, long, pinnated foliage, which ſpread open delightfully in fine weather, but rather droop and contract at the approach of bad. They flower in July, but being of an herbaceous colour, make but little appearance; but their large ſeed-pods have a fine effect, though theſe do not often attain perfection in England.

They are natives originally of America, but grow freely here in any ſituation.

Both the varieties are fine furniture for all ornamental plantations and ſhrubbery-work, &c. and have an admirable effect placed ſingly in large opens of graſs ground.

*Propagation.*

Their propagation is by ſeeds, which are annually procured from America by the ſeedſmen: ſow them in ſpring in a warm border of light earth half an inch deep, giving occaſional waterings in dry weather, and the plants will riſe the ſame ſeaſon, and by ſpring following, the largeſt will be fit to tranſplant, and in ſpring after all the reſt, planting them in nurſery-rows, one foot by two aſunder, to remain till a yard or two high.

GLOBULARIA, Globular blue Daiſy.

The plants are herbaceous, flowery perennials,

nials, producing annual ſtalks from about ſix, to ten, or twelve inches high, ſurmounted by globular heads of blue flowers.

Claſs and order, *Tetrandria Monogynia.*

*Characters.*] CALIX, a general cup, containing many florets, each having a monophyllous cup, five-parted at top. COROLLA, the general flower conſiſts of many florets collected into a globular head, each floret is monopetalous, tubular, and five parted at the brim. STAMINA, four filaments, and incumbent antheræ. PISTILLUM, an oval germen, ſingle ſtyle, and obtuſe ſtigma. PERICARPIUM, none, one ſeed to each floret, lodged in its calix.

There is but one ſpecies common to our gardens, viz.

GLOBULARIA *Vulgaris.*

*Common Globularia.*] Globularia, with broad, thick, radical leaves, three-parted at the ends; upright ſtalks from about ſix, to ten, or twelve inches high, garniſhed with ſpear-ſhaped leaves; and the top crowned by a globular head of fine blue flowers, compoſed of many florets in one general cup. See the *Characters.*

It flowers in June, and makes a good appearance towards the fronts of the flower-borders, but flowers beſt in a ſhady moiſt ſituation.

The propagation is effected by parting the roots in September.

GLORIOSA, Superb Lily.

It is a tender, herbaceous, flowering perennial for the ſtove, producing trailing, annual ſtalks ſeveral feet long and hexapetalous liliaceous flowers.

Claſs and order, *Hexandria Monogynia.*

*Characters.*] CALIX, none. COROLLA, ſix oblong, ſpear-ſhaped, waved, extremely long petals, wholly reflexed back. STAMINA, ſix ſpreading filaments, and incumbent antheræ. PISTILLUM, a globular germen, ſlender inclinated ſtyle, and triple ſtigma. PERICARPIUM, an oval, trilocular capſule, and many globular ſeeds.

There is but one ſpecies, viz.

GLORIOSA *Superba.*

*Superb Lily.*] Glorioſa, with a thick, fleſhy, tuberous root; ſending forth from its centre declinated round ſtalks, growing eight or ten feet long, garniſhed with very long, narrow leaves, running out to a point, terminated by a long tendril; and from the upper part of the ſtalks, large flame-coloured drooping flowers of ſix widely ſpreading reflexed petals.

It flowers in June and July, and is of admirable beauty, hence it derives the name *Glorioſa*, or Superb Lily.

This plant being a native of Ceylon and Malabar, very warm countries, requires the protection of the hot-houſe here, ſo muſt be kept in pots of light earth, and placed conſtantly in that department. The flower-ſtalks ſhoot forth in March or April, which being long, and of trailing growth, muſt have tall ſticks placed for their ſupport: water them frequently in ſummer during their growth, but give very little after their flowers and ſtalks decay.

The time for removing the roots either for encreaſe, or to tranſplant into freſh earth, &c. is, in autumn, when their ſtalks decay, or early in ſpring before they begin to ſhoot.

It is propagated by off-ſets of the roots, which they yield in tolerable plenty, and may be ſeparated any time after the ſtalks decay, or in ſpring before new ones ariſe.

GLYCINE, knobbed rooted Liquorice Vetch.

Of this Genus, is one ſhrubby climber, uſually cultivated for the ſhrubbery, adorned with noble pinnated foliage, and fine papilionaceous blue flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophyllous and bilabiated. COROLLA, is papilionaceous, having a heart-ſhaped vexillum, ſmall, oblong, oval wings; and narrow ſickle-ſhaped keel. STAMINA, ten diadelphous filaments, and ſingle antheræ. PISTILLUM, an oblong, germen, ſpiral ſtyle, and obtuſe ſtigma. PERICARPIUM, an oblong pod, and kidney-ſhaped ſeed.

The ſpecies commonly cultivated in our gardens is;

GLYCINE *Frutiſcens.*

*Shrubby Glycine, commonly called Carolina Kidney-bean-tree.*] Glycine, with ſhrubby climbing ſtalks twining round any ſupport, fifteen or twenty feet high, adorned with pinnated leaves of three pair of folioles, terminated by an odd one, and from the axillas, cluſters of large blueiſh-purple flowers, ſucceeded by long pods, like thoſe of the climbing kidney-beans.

It flowers in July and Auguſt, but the ſeeds do not ripen here.

This is an elegant ſhrubby climber, ornamental both in foliage and flowers, and merit a place in the beſt ſhrubberies.

It is eaſily propagated by ſeed, and by layers.

By Seed. This is imported annually from America. Sow it in ſpring in a bed of light earth, half an inch deep; give the young plants occaſional protection of mats from froſt the following winter; in ſpring plant out ſome of the largeſt in nurſery rows, and in ſpring after put out the remainder.

By Layers. In autumn lay down the young ſhoots in the earth, and by that time twelve-month they will be rooted and fit to tranſplant.

GLYCYRRHIZA, Liquorice.

This genus furniſhes one valuable herbaceous perennial for medical uſe, producing annual ſtalks a yard or more high, pinnated leaves, and papilionaceous flowers.

Claſs and order, *Diadelphia Decandria.*

*Characters.*] CALIX, is monophylous, tubular, and bilabiated. COROLLA, is papilionaceous, having a long, erect vexillum, oblong wings, and dipetalous carina. STAMINA, ten diadelphous filaments, and roundiſh antheræ. PISTILLUM, a ſhort germen, ſlender ſtyle, and riſing obtuſe ſtigma. PERICARPIUM, an oval or oblong pod, and kidney-ſhaped ſeed.

[1]GLYCYRRHIZA, *Glabra.*

*Smooth-podded Glycyrrhiza, or Common Liquorice.*] Glycyrrhiza, with a long, thick, creeping root, ſtriking ſeveral feet deep into the ground; upright, firm, herbaceous ſtalks annually, three or four feet high, garniſhed with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect ſpikes of pale blue flowers in July, ſucceeded by ſhort ſmooth pods.

The root of this is the uſeful part, which is replete with a ſweet, balſamic, pectoral juice, much uſed in all compoſitions for coughs and diſorders of the ſtomach.

[2]GLYCYRRHIZA, *Echinata.*

*Echinated or Prickly-podded Liquorice.*] It is nearly like the common ſort, only the ſeed-pods are prickly.

Both theſe ſpecies are very hardy perennials, but the firſt ſpecies is the ſort commonly cultivated for uſe, its roots being fuller of juice and ſweeter than the other.

The roots are perennial, but the ſtalks riſe in ſpring, and decay in autumn.

They delight in a deep light ſoil, in which the roots will run down three or four feet deep, and attain a large ſize if permitted to ſtand three or four years; and from the main root ſmaller ones run off horizontally, and from theſe horizontal roots, that run near the ſurface, cuttings for ſets or young plants are taken for propagation, which are generally procured at the time when the Liquorice is taken up for uſe, being fit in three years after planting.

Where large quantities are required for ſale, they may be cultivated in fields, as practiſed in many parts of England; vaſt quantities are alſo raiſed in the kitchen-gardens about London, where, by the richneſs and depth of the ground, the roots attain their utmoſt perfection in length and bulk.

The length and thickneſs of the roots is a principal conſideration to the planter, as they are always ſold by weight.

*Propagation and Culture.*

Their propagation is, as above obſerved, effected by cuttings of the ſmall roots iſſuing from the ſides of the main ones, near the ſurface of the earth, dividing them into lengths of ſix or eight inches, each having one or more good buds or eyes; and the proper ſeaſon for procuring the ſets for planting is, any time, in open weather, from October till March, though from the middle of February, till the middle of March, is rather the moſt ſucceſsful ſeaſon for planting.

An open ſituation is the moſt ſuitable for a plantation of theſe plants.

Particular regard ſhould alſo be had to the ſoil; it ought to be of a light, looſe temperature, and three or four feet deep if poſſible, for the roots of the Liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for ſale by weight.

Having fixed on the ground, let it be trenched three ſpades deep, if the depth of proper ſoil will admit, then having your ſets ready, proceed to plant them by line and dibble, planting the ſets a foot diſtance in each row; putting them perpendicular into the ground, with the tops about an inch under the ſurface, and let the rows be a foot and half aſunder; though the London gardeners ſeldom allow more than twelve inches between row and row; theſe gardeners alſo ſow a crop of onions on the ſame ground the firſt year, which, as the onions root but ſlender, and ſpread but little at top, may be done without any detriment to the Liquorice, nor that to the onions, as it does not riſe above ten or twelve inches high the firſt ſummer; obſerving to keep the ground clean from weeds during that ſeaſon by hoeing; and if there is a crop of onions, uſe the ſmall hoe,

cutting

cutting out the onions to four or five inches diſtance, clearing away ſuch as grow immediately cloſe to the Liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to looſen the ſurface and deſtroy all weeds effectually; and in autumn cut down the decayed ſtalks of the Liquorice, and nothing more is neceſſary to be done till ſpring; when, in February or March give a ſlight digging between the rows, and during ſpring and ſummer, keep down all weeds by broad-hoeing; and in autumn when the ſtalks are in a decaying ſtate, cut them down to the ſurface of the earth as before obſerved. The ſame work is to be repeated every ſucceeding year: that is, ſlightly ſtir the ground in ſpring, keeping down all weeds in ſummer in hoeing, but after the firſt or ſecond year, the ſtalks of the Liquorice will ſhoot ſtrongly, and ſoon cover the ground, ſo as greatly to retard the growth of weeds.

Likewiſe, every autumn, about October, when the ſtalks begin to decay cut them down to the ground and clear them off.

In three years after planting, the roots of the Liquorice will be fit to take up, and the proper ſeaſon for this is, any time from the beginning of November till February, for it ſhould neither be taken up before the ſtalks are fully decayed, nor deferred till late in ſpring, otherwiſe the roots will be apt to ſhrivel and diminiſh in weight.

The method of taking it up is by trenching the ground, beginning at one end, and open a trench cloſe to the firſt row three or four ſpades deep, or to the depth of the roots, at which work three or four ſpadeſmen are generally employed at each trench; one goes on with the top ſpit, a ſecond with the next ſpit, another with a third ſpit, and the fourth ſpadeſman commonly gets to the bottom of the roots, having a mattock to aſſiſt him occaſionally to clear them, ſo as he takes them up, throws them on the top of the undigged ground; and in this manner proceed row and row, till the whole plantation is taken up.

The ſmall ſide-roots are trimmed off, and the beſt divided into lengths for freſh ſets, and the main roots are tyed in bundles ready for ſale.

It is of advantage to ſell them as ſoon as poſſible after they are taken up, before they looſe much of their weight.

They are ſold to the druggiſts, from about twenty to thirty or forty ſhillings per hundred weight, and an acre of ground has produced three thouſand and upwards, which has been ſold for more than ſixty pounds, but the price is commonly in proportion to the goodneſs of the roots.

GNAPHALIUM, Cudweed, Goldylocks Eternal-flower, Everlaſting, &c.

This genus conſiſts of herbaceous and ſmall under-ſhrubby flowering perennials for the open ground and green-houſe, of different ſtatures, from ſix or eight inches, to four or five feet, adorned moſtly with white hoary leaves, and terminated by compound flowers in corymboſe cluſters, remarkable for retaining their beauty for years after being gathered.

Claſs and order, *Syngeneſia Polygamia Superflua.*

*Characters.*] CALIX, compound flowers, having a roundiſh, imbricated, permanent, general cup. COROLLA, many hermaphrodite and female florets in one general cup, the females have no petals. STAMINA, five filaments, and cylindric antheræ. PISTILLUM, an oval germen, filiform ſtyle, and bifid ſtigma. PERICARPIUM, none: the calix is permanent and gloſſy; and the ſeeds are ſingle under each floret, and crowned with down.

The moſt material ſpecies in the Engliſh gardens, are the following three hardy, and three tender kinds.

*Hardy Kinds.*

[1]GNAPHALIUM, *Margaritaceum.*

*Pearly-white Eternal-flower.*] Gnaphalium with creeping, very ſpreading roots, crowned with broad, ſpear-ſhaped, white, hoary leaves; herbaceous, thick, woolly ſtalks, a foot and half high, branching out upward, garniſhed with long, acute-pointed, white, woolly leaves placed alternate, and each branch terminated by a corymboſe cluſter of yelloviſh flowers, in large, prickly, white permanent cups appearing in June and July, are very ornamental; and which if gathered in a dry day ſoon after they appear, they will retain their beauty ſome years, hence it is often called everlaſting, or eternal flower.

This ſpreads and multiplies exceedingly by its creeping roots.

[2]GNAPHALIUM, *Plantaginifolium.*

*Plantain-leafed Cudweed*] Gnaphalium, with large oval, woolly, radical leaves; decumbent, running ſhoots rooting in the ground, and herbaceous, ſimple ſtalks ſix or eight inches high, terminated by a corymbus of white flowers in June, July, &c.

This alſo multiplies greatly by its off-ſet-runners rooting in the earth.

[3]GNAPHALIUM, *Stæchas.*

*Narrow-leafed Stæchas.*] Gnaphalium, with a ſhrubby ſtalk, branching into long, ſlender ſtalks three feet high, covered with a white bark, narrow leaves, hoary underneath, and all the branches terminated by compound corymboſe cluſters of yellow flowers appearing from May or June, to the end of ſummer, and which, if gathered dry, will continue ſome years.

*Tender Kinds.*

[4]GNAPHALIUM, *Orientale.*

*Oriental Goldy-locks, or Immortal Flower.*] Of which there are the following *Varieties.*

*Dwarf Oriental Goldy-locks.*—Hath a ſhort, ſhrubby ſtalk, a few inches high, branching out into many heads, garniſhed with narrow, woolly leaves, and from the heads, flower-ſtalks ſix or eight inches long, terminated by a compound corymbus of golden yellow flowers.

*Narrow-leafed, Oriental, Immortal Flower.*—Hath ſhrubby ſtalks, branching two or three feet high, long, ſpear-ſhaped woolly leaves, and the branches terminated by a compound corymbus of golden yellow flowers—likewiſe a variety with ſilvery white flowers.

*Broad-leafed Oriental Immortal Flower.*—Hath broad, ſpear-ſhaped, white, woolly radical leaves; woolly ſtalks branching a foot and half high, adorned with ſpear-ſhaped, woolly leaves; and the branches terminated by compound cluſters of golden yellow flowers.

Theſe three varieties of *Gnaphalium Orientale*, flower in May and June, and often continue in ſucceſſion great part of ſummer; and if thoſe of all the ſorts are gathered before they are too ripe, in a dry day, they remain beautiful for many years; hence the name Immortal flower, &c.

[5]GNAPHALIUM, *Orodatiſſimum.*

*Sweet-ſcented Eternal Flower.*] Gnaphalium with ſhrubby-winged ſtalks, branching irregularly a yard high, oblong, blunt leaves hoary underneath, and decurrent, having a wing or border running along the ſtalk or branch, and the branches terminated by compound, cloſe, corymboſe cluſters of bright gold-coloured flowers, changing to a dark yellow.

[6]GNAPHALIUM, *Arboreum.*

*Tree Gnaphalium.*] Gnaphalium, with a woody ſtem, branching four or five feet high, narrow ſeſſile leaves, with revolute borders, ſmooth on their upper ſide, and roundiſh bunches of pale yellow flowers.

The flowers of all theſe ſpecies of *Gnaphalium* are compound, having many ſmall florets, common to one general cup or calix, which is perſiſtant, dry, and ſhining, (ſee the *Characters*) and generally all terminate the branches in a compound, compact corymbus, and all of which poſſeſs the ſingular property of retaining their beauty in their proper colours for ſeveral years, if kept dry and clean.

Moſt of the ſorts come into flower about June, and continue great part of ſummer.

The firſt three ſorts are hardy, and may be employed as plants of ornament, in any compartment of the pleaſure-ground, for they will thrive in any ſoil and ſituation; the two firſt of which encreaſe exceedingly by their roots, and rooting ſhoots, which may be taken off in autumn or ſpring, and planted where they are to remain; and the third ſort being ſhrubby, is propagated by planting ſlips or cuttings of its ſhoots any time in ſpring or ſummer, in a ſhady border.

But the fourth, fifth, and ſixth ſpecies are ſomewhat tender, and ſome ſhould be kept in pots, to be ſheltered in a green-houſe or garden-frame, in winter; others may be planted in the full ground in a warm, dry ſituation, eſpecially the oriental kind, and varieties; alſo, the ſweet-ſcented ſort, for theſe two ſpecies will ſtruggle tolerably through an ordinary winter, and make a pretty appearance during the ſummer months. All theſe being ſhrubby, are propagated by ſlips or cuttings of their ſhoots, any time in ſpring or ſummer; planted either in borders of natural earth, and covered with hand-glaſſes till rooted, or by planting them in pots, and place them in a hot-bed, which will bring them forwarder.

GOMPHRENA, Globe Amaranthus.

Of this genus there is one tender, very ornamental, annual, and varieties, of two or three feet ſtature, adorned with ſimple entire foliage, and globular heads of aggregate florets.

Claſs and order, *Pentandria Digynia.*

*Characters.*] CALIX, many florets, collected into a capitulum or head, each having a diphyllous, coloured, permanent cup. COROLLA, numerous, ſmall, erect florets, collected into a cloſe head; each floret five-parted at the brim, and has a five-parted nectarium. STAMINA, five ſcarce diſcernible filaments. PISTILLUM, in each floret an oval germen, two ſmall ſtyles, and ſimple ſtigmas. PERICARPIUM, a ſmall roundiſh capſule, ſucceeding each floret, and one roundiſh ſeed.

The

The ſpecies is;

GOMPHRENA, *Globoſa.*

*Globoſe Gomphrena, commonly called Globe Amaranthus.*] Gomphrena, with an upright ſtalk, branching erectly all around, two or three feet high; the branches by pairs oppoſite, each pair croſſing the other; garniſhed with oval-lanceolate, oppoſite leaves, and every branch and ſide-ſhoot, terminated by a cloſe globular head of flowers, compoſed of numerous very ſmall ſtarry florets, cloſely covered with dry ſcaly calices, placed imbricatum, perſiſtent, and beautifully coloured, and in which conſiſts the beauty of the flowers, which are of different colours in the varieties.

*Varieties are.*] Globe amaranthus, with purple heads—with white or ſilvery heads—with red heads—with ſtriped or variegated heads—with ſpiked heads.

All theſe varieties are very floriferous and ornamental, they divide into many branches, each of theſe ſending forth many axillary foot-ſtalks, each ſupporting a round head of flowers, accompanied by two leaves, appearing from June till November, ſucceeded by plenty of ripe ſeeds.

They are tender plants of the annual tribe, riſing from ſeed in ſpring, and totally periſh at the approach of winter.

The flowers themſelves are ſeparately ſo ſmall, and cloſely covered with the ſcaly calices, that they ſcarcely appear; ſo that the numerous, cloſely placed, ſcaly coverings, being of a dry, firm conſiſtence, coloured and glittering, collected into a compact, round head, the ſize of an ordinary cherry, are very conſpicuous, and make a very ornamental appearance.

Theſe flowers, if gathered when at full growth, and placed out of the ſun, will retain their beauty ſeveral months.

The plants being natives of India, are of tender quality here, requiring aid of artificial warmth to raiſe and forward them to a proper ſtate of growth, ſo as to flower in perfection and produce ripe ſeed; therefore, they are raiſed in hot-beds under glaſſes in ſpring, and retained there till June, for they will not bear the open air here till the middle, or latter end of that month.

They are commonly cultivated in pots, and placed to adorn fore-courts, and other conſpicuous compartments, in aſſemblage with other curious annuals, though they may alſo be planted out into the open borders, &c.

*Propagation and Culture.*

All the varieties are propagated only by ſeed ſowed annually in March, or beginning of April, in hot-beds under glaſſes; as for *amaranthus*, and the *celoſia criſtata*, or *cocks-comb*.

The ſeeds being cloſely inveloped in their ſcaly, chaffy covering, it ſhould be pulled to pieces and ſeparated as well as poſſible, and having the hot-bed ready as directed for the amaranthus and other tender annuals, ſow the ſeed either in the earth of the bed, covering it a quarter of an inch deep with fine mold, or may be ſowed in pots, and plunge them in the hot-bed, as ſhall be convenient: the plants will come up in a week or ten days, and when they are an inch high, they ſhould be pricked down either in the ſame bed, if of good heat, or in a freſh one, three or four inches diſtance, giving water, occaſional ſhade, and freſh air. Here let them grow three weeks or a month, when they will be conſiderably encreaſed in growth, and ſhould be tranſplanted into another hot-bed, at ſix or eight inches diſtance, or may now plant them in pots, (thirty-twos) and plunge them in the hot-bed, under a deep frame, to draw them up tall, where they may grow till June, then ſhifted into larger pots, obſerving at each removal, to give water and ſhade occaſionally till rooted, and give freſh air daily at the upper end of the lights; and frequent waterings, managing them in every reſpect as directed for the amaranthus and cocks-comb, and other tender annuals. See ANNUAL PLANTS. And in June innure them gradually to the full air, and if any are not potted, tranſplant them therein with balls about their roots; and towards the latter end of that month may remove them into the full air entirely, at which time alſo, if you intend to plant any in the borders, ſhould then tranſplant them from the hot-bed with balls about their roots.

During ſummer, thoſe in the pots ſhould be watered three or four times a week in dry weather; towards Auguſt a pot or two of each variety for ſeed, ſhould be placed in a frame or glaſs-caſe, to be occaſionally ſheltered from exceſſive wet and cold nights, whereby they will ripen the ſeeds more effectually.

GOSSYPIUM, Cotton Plant.

This genus conſiſts of ſome herbaceous annuals, and ſhrubby perennials of the ſtove, riſing from two to five or ſix feet high, having divided leaves, and pentapetalous flowers, ſucceeded

ſucceeded by capſules filled with ſeeds, wrapped up in that fine downy matter called cotton.

Claſs and Order, *Monadelphia Polyandria.*

*Characters.*] CALIX, is double, the outer one large and half-trifid, the inner one cup-ſhaped, and indented at the brim. COROLLA, five heart-ſhaped, plane petals. STAMINA, numerous united filaments, and kidney-ſhaped antheræ. PISTILLUM, a roundiſh germen, a columnous ſtyle, and four thick ſtigmas. PERICARPIUM, a roundiſh, acuminated capſule, of three or four cells, filled with oval ſeeds, and fine down, called cotton.

The plants are cultivated in ſome of our hot-houſes for curioſity, and for which a plant or two of a ſort is ſufficient.

The chief ſpecies are;

[1]GOSSYPIUM, *Herbaceæ.*

*Common herbaceous Cotton.*] Goſſypium, with an herbaceous, ſmooth ſtalk, two feet high, branching upwards; five-lobed ſmooth leaves, and yellow flowers from the ends of the branches, ſucceeded by roundiſh capſules full of ſeed and cotton.

[2]GOSSYPIUM, *Hirſutum.*

*Hairy American Cotton.*] Goſſypium with hairy ſtalks branching laterally two or three feet high; palmated, three and five-lobed, hairy leaves, and yellow flowers, ſucceeded by large oval pods, furniſhed with ſeeds and cotton.

[3]GOSSYPIUM, *Barbadenſe.*

*Barbadoes Shrubby Cotton.*] Goſſypium, with a ſhrubby ſtalk, branching four or five feet high, three-lobed ſmooth leaves, glandulous underneath; and yellow flowers, ſucceeded by oval pods, containing ſeeds and cotton.

[4]GOSSYPIUM, *Arboreum.*

*Tree Cotton.*] Goſſypium, with an upright woody perennial ſtalk, branching ſix or eight feet high; palmated, four or five-lobed, ſmooth leaves, and yellow flowers, ſucceeded by large pods filled with ſeeds and cotton.

The firſt three ſpecies are principally annual, riſe from ſeed in ſpring, and periſh root and ſtalk in autumn, more eſpecially the firſt and ſecond ſorts.

But the fourth ſort is perennial in root and ſtalk.

It is theſe plants which produce the cotton for uſe, and in warm countries they are cultivated in great quantities in fields, as we do corn, particularly the annual ſorts; but the firſt ſpecies is the moſt commonly cultivated.

The pods are ſometimes as large as middling apples, cloſely filled with the cotton, ſurrounding the ſeed.

They are natives of the warm parts of America, ſo that if a plant or two of each is required here for variety, they muſt be raiſed and continued in the ſtove, where they will flower, and produce pods furniſhed with ſeeds and cotton.

Their propagation is by ſeed ſown in pots of light earth in ſpring, plunging them in the bark-bed, and when the plants are an inch or two high, prick them in ſeparate pots, which plunge alſo in the bark bed, and retain them always in the ſtove.

GRAFTING, a mode of propagation, particularly uſed for moſt ſorts of fruit-trees, being the only certain method to continue the approved varieties in their kind, and is alſo uſed for propagating many ſorts of flowering-ſhrubs and timber-trees.

This mode of propagation is, the taking a graft or ſhoot of one tree, and inſerting or ingrafting it into the ſtem or branch of another, and they both uniting as one, the graft ſhoots forth into branches and becomes the tree, producing flowers and fruit exactly the ſame as that of the tree from whence it was taken; and the grafting for all ſorts being always performed in ſpring, from about the end of January, until that of March, the grafts unite firmly the ſame ſeaſon, ſhoot forth in ſummer, ſo as by autumn, of the ſame year, they will often form ſhoots or young branches, from about a foot, to two or three long, and in ſome ſorts will bear fruit the ſecond or third year.

Hence the great utility of Grafting is to propagate any approved variety of choice fruit-trees, &c. whereby theyare with certainty preſerved perfect in their kinds; and trees of all ſorts may alſo be continued and multiplied by the ſame method of propagation: for as juſt hinted, the grafts or cions, i. e. cuttings of young ſhoots, being taken from any particular tree or ſhrub, and grafted upon others of the ſame genus; as, for inſtance, a golden-rennet apple upon a crab or any other kind of apple-ſtock, raiſed from ſeed or otherwiſe, the graft ſhoots up and becomes the tree, and bears golden-rennets the ſame in every reſpect as that of the tree from whence the cions were taken; ſo that Grafting is the principal certain method to continue any approved varieties: for although the different varieties of fruit have been accidentally obtained from ſeeds, yet ſow the ſeeds of the fineſt ſorts, they will

degenerate

degenerate ſo greatly by ſeeds, that out of hundreds ſo raiſed, there probably may not be one tree which produces fruit like the original, or perhaps that poſſeſs any good quality for eating; and the ſame is obſervable of all other fruits, ſo variable is ſeedling fruit-trees; and hence it was, that the ancients, finding there was no certainty in continuing and multiplying the approved varieties of fruit from ſeed, they invented the art of Grafting, and inoculation, both of which proving effectual and invariable, is ſtill continued in the propagation of almoſt all the varieties of every genus of fruit-trees; for whatever be the ſtock or tree, on which you perform the Grafting, if of the ſame genus, the graft will grow freely, and always remain unalterably the ſame; that is, always producing the ſame ſort of fruit as its parent tree, which renders graſting of general utility in gardening, but more particularly for fruit trees; though ſome ſorts, as vines, figs, quinces, mulberries, currants, gooſeberries, &c. are moſt commonly propagated by layers and cuttings of their branches, which ſtriking root freely in the ground, ſhoot up into ſtem and branches, and, like the grafts, produce fruit alſo exactly the ſame as the tree from whence they were taken. But as moſt other ſorts of fruit-trees ſucceed much better by Grafting and budding, that method is commonly practiſed in their propagation; many curious varieties of ornamental trees and ſhrubs may alſo be propagated with certainty by Grafting and budding, particularly all the ſtriped and variegated-leafed varieties, as alſo all other varieties of any particular ſpecies.

By Graſting alſo, different ſorts of fruit and flowers of the ſame genus, may be made to grow upon one tree; as for inſtance, grafts of ſeveral ſorts of apples may be ingrafted into the ſame tree, each graft branching out, produces fruit in every reſpect like that of the tree from whence they were cut; by the ſame rule you may alſo, for curioſity, have ſeveral ſorts of pears on one tree, alſo apples and pears on the ſame tree or branch, as being all of the ſame fraternity or genus, the ſame is alſo obſervable of all other trees of the ſame genus or family; for it is in but very few inſtances that trees of a different genus will grow upon each other, by Grafting or budding, though the almond, peach, and nectrine, being all of the genus *Amygdalus* will grow upon the *Prunus* or plum-tree, and which is the common ſtock on which theſe kinds are uſually worked, but theſe kinds excepted, all other kind of fruits ſucceed beſt upon ſtocks or trees of their own family.

*Of the proper Stocks, &c. to graft upon.*

With reſpect to the ſtocks, or trees, on which to perform the operation of Grafting, it is moſt commonly performed upon the ſtems of young trees, raiſed from the ſeed, layers or cuttings for that purpoſe; though they are the moſt commonly raiſed from ſeed, except in particular caſes; and when deſigned for the purpoſe of Grafting upon, are always denominated ſtocks, which, when from about the ſize of a gooſe quill, to an inch or more in diameter, are of due ſize for receiving the grafts; obſerving, that previous to the inſertion of the grafts, the head of each ſtock muſt be cut off, from within about ſix inches to as many feet of the ground, according whether the tree is deſigned for a dwarf, or a half, or full ſtandard; and one graft is commonly inſerted into each ſtock, though in large ſtocks ſometimes two or more grafts are inſerted: remarking, that if intended to raiſe dwarf-trees, the ſtock, at the time of Grafting, muſt always be headed down within a few inches of the ground, for the inſertion of the graft; and for ſtandards, the heading of the ſtock for the inſertion of the graft may either be near the ground, and train up one of the firſt ſhoots from the graft to form a ſtem; or if you deſign the ſtock to form the ſtem, as is common for ſtandard cherries, &c. it muſt be ſuffered to grow ſix or ſeven feet high, ſo head it at four, five, or ſix feet height for the reception of the grafts.

But Grafting is alſo performed upon old trees, or ſuch as already bear fruit, particularly when it is deſigned to change the ſorts, or have more than one ſort on the ſame tree; or to renew the whole, or any particular branch of a tree: in either caſe, inſerting the graft into the upright branches, ſometimes heading the branches down for its reception, and ſometimes inſerting it into their ſides without heading them down. But as there are five or ſix different methods of Grafting, each is exhibited below.

The particular ſorts of ſtocks proper for Grafting each ſort upon, is fully exhibited under each reſpective article as they occur in the courſe of this work.

Let it however be remarked, both in Grafting and inoculation, that, as above noticed, the different varieties of each genus,

whether

whether fruit-trees, foreſt-trees, ſhrubs, &c. muſt always be grafted upon ſtocks or trees of the ſame family, or ſuch that are very near kindred by the *characters* of their flower, otherwiſe they will not ſucceed; as for example, apples ſhould be grafted only upon apple-ſtocks, i. e. young trees raiſed from the kernels of any kind of apple whatſoever: they will however alſo grow upon pear and quince ſtocks, as being all of the ſame genus; but they always ſucceed beſt upon any kind of apple-ſtocks, raiſed either from the kernels of the wild crab, or thoſe of any of the cultivated apples. Pears likewiſe ſucceed beſt upon pear-ſtocks, or to have them dwarfs, are grafted upon quince-ſtocks. Plums ſhould be grafted principally upon plum-ſtocks, though they will grow upon thoſe of cherries, and cherries upon theſe, they being all of the ſame genera; but each ſucceed conſiderably beſt upon their own ſtocks. Cherries ſhould therefore likewiſe be grafted upon cherry-ſtocks: but for particulars of each kind, ſee the ſeveral articles under their reſpective genera.

As to the method of raiſing the different ſorts of ſtocks for Grafting, it is moſt commonly by ſeed, kernels, or ſtones of the reſpective fruits, ſowed in autumn or ſpring, in beds of good earth, covering them with mold about an inch or two deep, according to their ſorts or ſizes; they will come up early in ſummer, and be fit to plant in nurſery rows, two feet aſunder, in winter and ſpring following; and in the ſpring after, many of them will be fit to whip-graft; but when they are from two to five or ſix years old, they will be ſuitable for one or other of the ſeveral methods of Grafting.

Stocks are alſo ſometimes raiſed by layers and cuttings of the young ſhoots of particular trees of each reſpective genus, when deſigned to have ſtocks for Grafting particular varieties of fruit upon, as exhibited under their proper articles.

Stocks are likewiſe raiſed from ſuckers ariſing from the roots of the trees of the reſpective ſorts, tranſplanting them into the nurſery in autumn; to remain a year or two, and then may be grafted.

But the particular ſtocks and method of raiſing them is fully exhibited under the reſpective articles, which ſee; alſo the articles NURSERY and STOCKS.

*Of the proper Grafts.*

The grafts or cions, with which the Grafting is effected, are young ſhoots of the laſt ſummer's growth, for they muſt not be more than one year, and ſuch that grow on the outſide branches, and robuſt but moderate ſhooters, ſuch alſo that are firm and well ripened, ſhould always be choſen from healthful trees, obſerving, that the middle-part of each ſhoot is always the beſt grafts: cut at the time of Grafting, to five or ſix inches in length, or ſo as to have four or five good eyes or buds, but ſhould preſerve them at full length till Grafting time, then prepared as hereafter directed.

They ſhould be collected or cut from the trees in February, in mild weather, before their buds begin to ſwell, or advance much for ſhooting: in collecting them, chuſe ſuch as have not made any lateral or ſide ſhoots; cut them off at full length, and if they are not to be uſed as ſoon as they are collected, lay their lower ends in ſome dry earth in a warm border till Grafting time, and if ſevere weather ſhould happen, cover them with dry litter.

*Neceſſary Materials uſed in Grafting.*

The proper tools and other materials uſed in Grafting, are

A ſtrong knife for cutting off the heads of the ſtocks, previous to the inſertion of the graft, alſo a ſmall hand-ſaw for occaſional uſe in cutting off the heads of large ſtocks.

A common Grafting-knife, or ſtrong, ſharp pen-knife, for cutting and ſhaping the grafts ready for inſertion; alſo to ſlope and form the ſtocks for the reception of the grafts.

A flat Grafting-chiſſel and ſmall mallet for cleſting large ſtocks, in cleft-grafting, for the reception of the graft.

A quantity of new baſs-ſtrings for bandages, for tying the grafted parts cloſe, to ſecure the grafts, and promote their ſpeedy union with the ſtock.

And, a quantity of Grafting-clay, for claying cloſely round the grafts after their inſertion and binding, to defend the parts from being dried by the ſun and winds, or too much liquified by wet, or pinched by cold; for theſe parts ought to be ſo cloſely ſurrounded with a coat of clay in ſuch a manner as effectually to guard them from all weathers, which would prove injurious to young grafts, and deſtroy their cementing property, ſo as to prevent the junction; therefore, a kind of ſtiff loamy mortar muſt be prepared of ſtrong fat loam, or in default thereof, any ſort of tough binding clay, either of which ſhould

ſhould be laid in an heap, adding thereto about a fourth of freſh horſe-dung free from litter, and a portion of cut hay, mixing the whole well together, and add a little water, then let the whole be well beaten with a ſtick upon a floor, or other hard ſubſtance; and as it becomes too dry, apply more water, at every beating turning it over, always continue beating it well at top till it becomes flat; which muſt be repeated more or leſs according to the nature of the clay, but ſhould be ſeveral times beaten the firſt day; and next morning repeat the beating, ſtill moiſtening it with water, and by thus repeating the beating ſix or eight times every day for two or three days, or every other day at leaſt, for a week, it will be in proper order for uſe; obſerving it ſhould be prepared a week at leaſt before it is uſed, but if a month the better.

*Time and Method of Performing the Work of Grafting.*

The ſeaſon for performing the operation of Grafting is February and March, though, when the work is performed in February, it for the general part proves the moſt ſucceſsful; more eſpecially for cherries, plums, and pears, and March Grafting is well adapted for apples.

There are different methods of Grafting in practice, termed, Whip-grafting—Cleft-grafting—Crown-grafting—Cheek grafting—Side-grafting—Root-grafting—and Grafting by approach or inarching; but Whip-grafting and Cleft-grafting is moſt commonly uſed, and Whip-grafting moſt of all, as being the moſt expeditious and ſucceſsful of any.

*Whip-grafting.*—This being the moſt ſucceſsful method of all Grafting is the moſt commonly practiſed in all the nurſeries; it is always performed upon ſmall ſtocks, from about the ſize of a gooſe-quill, to half an inch or a little more or leſs in diameter, but the nearer the ſtock and graft approach in ſize the better; and is called Whip-grafting, becauſe the grafts and ſtocks being nearly of a ſize, are ſloped on one ſide, ſo as to fit each other, and tyed together in the manner of whips, or joints of angling-rods, &c. and the method is as follow;

Having the cions or grafts, knife, bandages, and clay ready, then begin the work by cutting off the head of the ſtock at ſome clear ſmooth part thereof; this done, cut one ſide ſloping upward, about an inch and half, or near two inches in length, and make a notch or ſmall ſlit near the upper part of the ſlope downward about half an inch long, to receive the tongue of the cion; then prepare the cion, cutting it to five or ſix inches in length, forming the lower end alſo in a ſloping manner, ſo as exactly to fit the ſloped part of the ſtock, as if cut from the ſame place, that the rinds of both may join evenly in every part; and make a ſlit ſo as to form a ſort of tongue to fit the ſlit made in the ſlope of the ſtock; then place the graft, inſerting the tongue of it into the ſlit of the ſtock, applying the parts as evenly and cloſe as poſſible; and immediately tye the parts cloſely together with a ſtring of baſs, bringing it in a neat manner ſeveral times round the ſtock and graft; then clay the whole over near an inch thick on every ſide, from about half an inch or more below the bottom of the graft, to an inch over the top of the ſtock, finiſhing the whole coat of clay in a kind of oval globular form, rather longways up and down, cloſing it effectually about the cion, and every part, ſo as no ſun, wind, nor wet may penetrate, to prevent which, is the whole intention of claying; obſerving to examine it now and then, to ſee if it any where cracks or falls off, and if it does, it muſt be inſtantly repared with freſh clay.

This ſort of Graſting may alſo be performed, if neceſſary, upon the young ſhoots of any bearing tree, if intended to alter the ſorts of fruits, or have more than one ſort on the ſame tree.

By the middle or latter end of May, the grafts will be well united with the ſtock, as will be evident by the ſhooting of the graft; then the clay ſhould be wholly taken away, but ſuffer the baſs bandage to remain ſome time longer, until the united parts ſeem to ſwell, and be too much confined by the ligatures, then take the tying wholly off.

Their farther culture is directed under the reſpective articles, whether deſigned for dwarfs or ſtandards, &c.

*Cleft-grafting.*—This is called Cleft-grafting, becauſe the ſtock being too large for Whip-grafting is cleft or ſlit down the middle for the reception of the graft; and is performed upon ſtocks from about one to two inches diameter.

Firſt, with a ſtrong knife cut off the head of the ſtock, or if the ſtock is very large, it may be headed with a ſaw; and cut one ſide

ſloping upwards about an inch and half to the top; then proceed with a ſtrong knife or chiſſel, to cleave the ſtock at top, croſs-way the ſlope, fixing the knife or chiſſel towards the back of the ſlope, and with your mallet ſtrike it, ſo as to cleave the ſtock about two inches, or long enough to admit the graft, keeping it open with the chiſſel; this done, prepare the cion, cutting it to ſuch length as to leave four or five eyes, the lower part of which being ſloped on each ſide, wedge-faſhion, an inch and half, or two inches long, making one ſide to a thin edge, the other much thicker, leaving the rind thereon, which ſide muſt be placed outward in the ſtock; the cion being thus formed, and the cleft in the ſtock being made and kept open with the chiſſel, place the graft therein at the back of the ſtock the thickeſt ſide outward, placing the whole cut part down into the cleft of the ſtock, making the rind of the ſtock and graft join exactly; then removing the grafting chiſſel, each ſide of the cleft will cloſely ſqueeze the graft, ſo as to hold it faſt; it is then to be bound with a ligature of baſs, and clayed over, as obſerved in Whip-grafting, leaving three or four eyes of the cions uncovered.

If intended to graft any pretty large ſtocks or branches by this method, two or more grafts may be inſerted in each; in this caſe the head muſt be cut off horizontally, making no ſlope on the ſide, but ſmooth the top, then cleave it quite a-croſs, and place a graft on each ſide, as the ſtock may be cleft in two places, and inſert two grafts in each cleft; they are thus to be tied and clayed as in the other methods.

This method of Grafting may be performed upon the branches of bearing trees, when intended either to renew the wood, or change the ſort of fruit.

Towards the latter end of May, or the beginning of June, the junction of the graft and ſtock in either methods, will be effectually formed, and the graft begin to ſhoot, when the clay may be taken off, and in a fortnight or three weeks after, take off alſo the bandages.

*Crown-grafting.*—This kind of grafting is commonly practiſed upon ſuch ſtocks as are too large to cleave, and is often performed upon the large branches of apples and pear-trees, &c. that already bear fruit, when it is intended to change the ſorts, or renew the tree with freſh-bearing wood, and is termed Crown-grafting, becauſe the ſtock or branch being headed down, ſeveral grafts are inſerted at top all around betwixt the wood and bark, ſo as to give it a crown-like appearance; obſerving that this kind of Grafting ſhould not be performed until March, or early in April, for then the ſap being in motion, renders the bark and wood of the ſtock much eaſier to be ſeparated for the admiſſion of the graft.

The manner of performing this ſort of Grafting is as follows:

Firſt cut off the head of the ſtock or branch with a ſaw horizontally, and pare the top ſmooth, then having the grafts, cut one ſide of each flat, and ſomewhat ſloping, an inch and half long, forming a ſort of ſhoulder at top of the ſlope to reſt upon the crown of the ſtock; and then raiſing the rind of the ſtock with a wedge, ſo as to admit the cion between that and the wood two inches down, which done, place the grafts with the flat ſide next the wood, thruſting it down far enough for the ſhoulder to reſt upon the top of the ſtock, and in this manner may be put three, four, five or more grafts in one large ſtock or branch.

When the grafts are all thus inſerted, let the whole be tied tight and well clayed, obſerving to leave two or three eyes of each graft uncovered, but raiſing the clay an inch above the top of the ſtock, ſo as to throw the wet quickly off, without lodging about the grafted parts, which would ruin the whole work.

Crown-grafting may alſo be performed, by making ſeveral cleſts in the crown of the ſtock, and inſerting the graſts round the top into the cleſts.

The grafts will be pretty well united with the ſtock, and exhibit a ſtate of growth by the end of May, or beginning of June, and the clay may then be taken away.

The trees graſted by this method will ſucceed extremely well, but for the firſt two or three years, have this inconvenience attending them, of being liable to be blown out of the ſtock by violent winds, which muſt be remedied by tying long ſticks to the body of the ſtock or branch, and each graft tied up to one of the ſticks.

*Cheek grafting.*—Cut the head of the ſtock off horizontally, and pare the top ſmooth, then cut one ſide ſloping an inch and half, or two inches deep, and cut the lower part of the graft ſloping the ſame length, making a ſort of ſhoulder at top of the ſloped part;

it

it is then to be placed upon the ſloped part of the ſtock, reſting the ſhoulder upon the crown of it, bind it with baſs, and finiſh with a covering of clay as in the other methods.

*Side-grafting.*—This is done by inſerting grafts into the ſides of the branches without heading them down, and may be practiſed upon trees to fill up any vacancy, or may do it for variety, to have ſeveral ſorts of apples, pears, plums, &c. upon the ſame tree.

It is performed thus: fix upon ſuch parts of the branches where wood is wanting to furniſh the head, or any part of the tree, there ſlope off the bark and a little of the wood, and cut the lower end of the grafts to fit the part as near as poſſible, then join them to the branch, and tye them with baſs, and clay them over.

*Root-grafting.*—This is done by Whip-grafting cions upon pieces of the root of any tree of the ſame genus, and plant the root where it is to remain; it will take root, draw nouriſhment, and feed the graft.

*Grafting by Approach or Inarching.*—This ſort of grafting is, that when the ſtocks deſigned to be grafted, and the tree from which you intend to take the grafts, either grow ſo near, or can be placed ſo near together, that the branch or graft may be made to approach the ſtock, without ſeparating it from the tree, till after its union or junction with the ſtock; ſo that the branch or graft being bent to the ſtock, they together form a ſort of arch; it is called Grafting by Approach, or Inarching, and as being a ſure method, is commonly practiſed upon ſuch trees as are with difficulty made to ſucceed by any of the former ways of Grafting, as hinted in their propagation.

When intended to propagate any kind of tree or ſhrub by this method of Grafting, if the tree, &c. is of the hardy kind, and growing in the full ground, a proper quantity of young plants for ſtocks muſt be ſet round it; and when grown of a proper height, the work of inarching muſt be performed, or, if the branches of the tree you deſign to graft from is too high for the ſtocks, in that caſe ſtocks muſt be planted in pots, and a ſlight ſtage muſt be erected around the tree, of due height to reach the branches, and the pots containing the ſtocks muſt be placed upon the ſtage.

As to the method of performing the work; obſerve, that in this method of Grafting, it is ſometimes performed with the head of the ſtock cut off, and ſometimes with the head left on till the graft is united with the ſtock, though by previouſly heading the ſtock, the work is much eaſier performed; and having no top, its whole effort will be directed to the nouriſhment of the graft; having however the ſtocks properly placed, either planted in the ground, or in pots around the tree to be propagated; then make the moſt convenient branches approach the ſtock, and mark on the body of the branches the parts where they will moſt eaſily join to the ſtock, and in thoſe parts of each branch pare away the bark and part of the wood two or three inches in length, and in the ſame manner pare the ſtock in the proper place for the junction of the graft, then make a ſlit upward in the branch, ſo as to form a ſort of tongue, and make a ſlit downward in the ſtock to admit it; let the parts be then joined, ſlipping the tongue of the graft into the ſlit of the ſtock, making the whole join in an exact manner, and tye them cloſely together with baſs, and afterwards cover the whole with a due quantity of clay, as before directed in the other methods.

After this, let a ſtout ſtake be fixed, if poſſible, for the ſupport of each graft, to which let that part of the ſtock and graft be faſtened, which is neceſſary to prevent their being disjoined by the wind.

The operation being performed in ſpring, let them remain in that poſition about four months, when they will be united, and the graft may then be ſeparated from the mother-tree; in doing this, be careful to perform it with a ſteady hand, ſo as not to looſen or break out the graft, ſloping it off downwards cloſe to the ſtock; and if the head of the ſtock was not cut down at the time of Grafting, it muſt now be done cloſe to the graft, and all the old clay and bandage muſt alſo be cleared away, and replaced with new, to remain a few weeks longer.

Obſerve however, that if you ſhall think the grafts are not firmly united with the ſtock, in the period of time above-mentioned, let them remain another year till autumn, before you ſeparate the grafts from the parent tree.

By this kind of Grafting, you may raiſe almoſt any kind of tree or ſhrub, which is often done by way of curioſity, to ingraft a fruit-bearing branch of a fruit-tree upon any common ſtock of the ſame fraternity or genus, whereby a new tree bearing fruit, is raiſed in a few months; this is ſometimes practiſed upon orange and lemon-trees, &c. by Graft-

ing bearing-branches upon ſtocks raiſed from the kernels of any of the ſame kind of fruit, or into branches of each other, ſo as to have orange, lemons, and citrons all on the ſame tree.

GRASS, Graſs Lawns, &c. for ornament to pleaſure-gardens.

In modern gardening, a ſpacious Graſs lawn extended in the front of the main habitation is the prevailing taſte, where, by its conſtant verdure, ſummer and winter, and open rural extenſion, exhibits a fine imitation of nature at all ſeaſons, eſpecially when each ſide-boundary terminates in rural plantations in various irregular concave, and convex curves, to take off all appearance of formality. Rural Graſs openings are alſo continued between the plantations throughout the different diſtricts of the pleaſure ground, ſeparateing and bounding the ſhrubbery clumps, &c. in ſome places widely ſpread, in others more contracted; in either caſe, extended to the boundaries of the ſeveral plantation compartments, in various irregular ſweeps and curves, which renders the whole rurally ornamental; and is agreeable and more eaſy to walk on than gravel between the plantations in dry hot weather in ſummer.

Straight Graſs walks prevailed greatly in the antient ſtyle of gardening, both for ornament and common walking; but in both theſe conſiderations, they are improper for general uſe, being attended with ſeveral inconveniencies; thoſe for ornament, unleſs they are elegantly wide and ſpacious, they have a littleneſs in their general appearance, as is obſervable in many places where long narrow ſlips of Graſs are extended to a great length, by way of walks; and with regard to having Graſs walks for common walking, they are very improper in winter, and all moiſt weather; alſo even in ſummer, in mornings and evenings, as being then always damp and dewy, which renders them very uncomfortable, as well as unſafe to ſome, with reſpect to health, to walk on them; and by conſtant walking and wheeling upon, they are often rendered bare, like a path, ſo as to appear very unſightly; Graſs walks therefore, ſhould be but ſparingly introduced, and when intended to have any, either for variety, ornament, or ſummer's walking, let it be ſpacious, not leſs than fifteen or twenty feet wide, if extended to any conſiderable length.

The method of laying or making all Graſs-work in gardens, is either by ſowing it with Graſs-ſeed, or by laying it with turf, cut from a fine common or down, the latter of which, where it can be obtained at a moderate expence, is greatly preferable; it not only at once forms a complete ſward, but is generally more cloſe, even, and ſmooth, not apt to run up to benty Graſs, or grow rank, nor riſe in tufts.

In preparing the ground either for ſowing or laying with turf, the whole ground muſt be broken up equally a moderate ſpade deep, clearing out all roots of perennial weeds; and then having ſtakes or wooden pegs, levelled in by notches, for your mark of level, agreeable to the laws of proportion, and the poſition of the ground, proceed with line and ſpade, to rough-level it, according to the ſaid mark or level on the pegs, and then tread or ram the whole down equally, that it may no where ſink in hollows hereafter; this done, work off your levels more acurately, and finiſh the whole with a neat raking, clearing off all large ſtones, making an even and ſmooth ſurface; and it is then ready, either for ſowing with ſeed, or to be laid with turf.

As it may in ſome places be the moſt convenient to ſow the ground with Graſs ſeed, and in others, to lay it with turf, we will exhibit both methods ſeparately.

*By Seed.*

By ſowing with ſeed.—If intended to ſow the ground with Graſs-ſeed, as may be the caſe for large ſpaces of ground, or where turf cannot be conveniently obtained, the ſeaſon for ſowing it is February, March, and April, and will come up fine and green in a month or ſix weeks; and if ſown in Auguſt or September, in moiſt weather, it will alſo riſe very faſt and thick before winter. The chief article is to procure good ſeed; thoſe from under a common hay-ſtack, or out of a hay-loft, are often uſed, which may do very well, provided the hay was the growth of ſome fine paſture free from weeds, and affords naturally fine turf when grazed and mowed, but without attending to theſe particulars, there are often a mixture of various ſorts, weeds and all, whereby the ſward will be very irregular and foul, and never make handſome Graſs. If you are not furniſhed with ſeeds of your own, they may be obtained cheap enough of the ſeeds-men; it muſt be ſowed by broad-caſt, very thick and regular, and directly rake it in, and roll it when the ſurface is dry with a wooden roller, which will bury the ſeed

ſeed more effectually, and make a ſmooth ſurface; when the Graſs comes up, pull up all weeds, and, the ſame ſeaſon when the ſward is become thick and green, and advanced ſome inches, it ſhould be mowed, and after this roll it well, and ſo continue mowing it, &c. two or three times the firſt ſummer, eſpecially if it was ſowed in ſpring; and the oftener it is mowed and rolled, the thicker and finer it will grow, obſerving, if intended to keep the Graſs tolerably fine, mowing will be requiſite once a week or fortnight according to its growth, from April until October, and ſhould be rolled once a week in all open weather the year round.

*By Turf.*

Laying the ground with turf, when turf can be eaſily procured, ſhould always be greatly preferred to ſeed for Garden-graſs, for the reaſons before mentioned, and the beſt turf for that purpoſe is, that of a fine paſtured common or down, where the ſward is fine and the Graſs ſhort.

The ſeaſon for laying turf is any time from September till April or May, though it will grow at almoſt any time of the year, even if there is occaſion to lay it in ſummer, and dry weather ſucceed; for although it will divide or open wide at the joints, and turn brown as if dead, yet after the firſt rain it will cloſe again, and reſume its verdure.

The turf for this uſe, is cut or flead with an iron inſtrument called a turfing-iron, which ſee, obſerving to cut them all an equal width, length, and thickneſs; the proper ſize is a foot wide, yard long, and about an inch thick; they ſhould be firſt marked by line, the proper width, length, and depth, with a racer or rutter. See RACER. Racing them firſt long ways a foot wide, then acroſs in yard lengths, then proceed to cut them up, having particular regard to cut them level, all an equal thickneſs, otherwiſe it will be impoſſible to lay them level; as you cut, a man or boy ſhould roll each turf up cloſe and tight, the Graſs ſide inwards, and pile them up by tens, eſpecially if they are cut by the hundred.

If they are cut by the hundred, the price is from ſix-pence to a ſhilling, according to the nature of the ſoil, whether ſoft and eaſy to cut, or hard or ſtoney; and a man will cut from three to five, ſix, or ſeven hundred in a day, or more, if very ſoft eaſy cutting turf, having a perſon to race them out and roll them up, turf and turf as they are cut, out of the way of the cutter.

As to the method of laying them, it is very eaſy; they are to be laid regular, turf and turf, unrolling them as you lay them, joining them up quite cloſe edge to edge, making good all deficiency of broken parts as you go on; and as ſoon as laid, it ſhould be well beaten with broad heavy wooden beaters, being flat pieces of elm or oak plank, two inches thick, fifteen or eighteen inches long, and a foot broad, having a long handle fixed ſlanting in the middle of the upper ſide; and with theſe beat the graſs regularly all over, and then roll it well with a heavy iron or ſtone roller, and the work is finiſhed, obſerving, the beating and rolling ſhould be repeated in moiſt weather.

If very dry hot weather ſucceeds, ſo as to occaſion the turf to ſhrink and open at the joints, a good watering will be of much advantage; do not however, be under much anxiety about this, for, as before hinted, the firſt rain will join all cloſe, and recover the verdure of the Graſs effectually.

*Its general management throughout the Year.*

The culture neceſſary for garden Graſs, is frequent mowing in ſummer, to keep it ſhort and fine like a paſtured down; poleing occaſionally with a long pole, to ſcatter the worm-caſts, which ſo greatly deface all graſs; frequent rollings both to take up the ſcattered worm-caſts to make the ſurface clean, and to render it ſmooth and firm.

As to mowing; to keep Graſs in gardens very neat, mowing it once a week or ten days during the ſummer is neceſſary, eſpecially for the principal home-lawns, and other Graſs-ground in the moſt conſpicuous parts of the garden, which parts ſhould always be kept very cloſe and fine, like the ſward of a fine paſtured down or common: the mowing of garden Graſs is performed with a ſhort-Graſs ſcythe, ſee MOWING, and SCYTHE, &c. obſerving, that dewy mornings, or moiſt weather muſt always be choſen for that work, for it will be impoſſible to mow ſhort Graſs properly in dry weather. But previous to mowing, it is of great advantage to pole and roll the Graſs the day before you intend to mow; in performing the mowing, great attention is neceſſary not to ſcore, i. e. leave the mark of each ſtroke of the ſcythe, which has a very unſightly appearance; to prevent which, as much as poſſible, have your ſcythe laid out rather

rather wide, an inch or two beyond heel and toe, eſpecially for very ſhort Graſs; and in mowing, keep the point rather out, and do not draw that part two faſt toward, gathering your Graſs neatly to the left in a range, and having mowed to the end of the ſwarth, mow it lightly back again, to trim off all ſcores, and other irregularities, unavoidably left the firſt time.

As ſoon as you have done mowing, proceed to ſweep up the mowing, each ſwarth regularly by ſtanding in the middle, ſweeping it along alternately to the right and left to the end of the ſwarth, forming all the Graſs thereof in a range on each ſide, then ſweep up the ranges in large heaps, and carry the whole off directly in a wheel-barrow or large baſket.

Poleing the Graſs. This is performed with a long taper pliable aſhen-pole, fifteen or eighteen feet long, to break and ſcatter the worm-caſts about, i. e. thoſe little lumps of earth caſt up by the worms all over the ſurface of the Graſs and greatly deface it; but by uſing the pole, when they are moderately dry, ſweeping it backward and forward upon the Graſs, breaks the earthy lumps into ſmall particles, and ſcatters them about, and if the Graſs is afterwards rolled with a wooden roller when the ſurface is a little moiſt, but not too wet, the earth will all adhere to the roller, and render the ſurface perfectly clean; obſerving this work ſhould be repeated, as you ſhall ſee occaſion the year round, and in mowing time, if the ſurface is foul, it is particularly neceſſary to pole and roll on the day previous to mowing, whereby, having a clean ſmooth ſurface, you will be able to mow cloſe, even, and expeditiouſly.

Rolling garden Graſs, is performed occaſionally with a wooden roller, and a heavy iron or ſtone roller: a wooden roller is proper always after poleing as obſerved above, to clean up the worm-caſts and ſmooth the ſurface, obſerving this work ſhould never be performed when the ſurface is very wet, eſpecially if full of worm-caſts, as it would plaiſter and daub the graſs very much, and render it unſightly; a heavy iron or ſtone roller ſhould be uſed occaſionally, to preſs down all inequalities cloſe, ſo as to preſerve a firm, even, ſmooth ſurface. Rolling is always of particular ſervice, performed occaſionally the day before mowing, as it greatly contributes to the eaſy and exact performance of that work; the work of rolling is in ſmall, or but moderately large gardens, always performed by men, but in very extenſive grounds, it is done by horſe, having a large roller for that purpoſe, with ſhafts like a cart, &c. and the horſe ſhould at that time wear leather ſhoes, very broad at bottom, made to lace on occaſionally like men's half-boots.

In ſome places the Graſs is greatly defaced in May and June by the vaſt quantities of wild daiſies daily ariſing, to remedy which, as much as poſſible, I have had the blade of an old broad ſword, fixed in the end of a long pliable pole, and as a ſword cuts both ways, by ſweeping it backwards and forwards, it will head down the daiſies a great pace, which may be repeated two or three times a week, or as often as there may be occaſion.

GRAVEL. Gravel-walks are great ornaments to gardens, as well as the moſt uſeful kinds of walks for common walking.

The beſt Gravel for walks is that which is compoſed naturally of irregular pebbles and flints, having a moderate proportion of a yellowiſh or browniſh ſandy loam, to make it bind and give colour; which kind of Gravel is the moſt common and valuable of all for walks, and is obtained in fields and commons in moſt parts of England, at about from one to three or four feet under the ſurface, though not equally good in all parts in reſpect to quality and colour; ſome may have a greater or leſſer quantity of pebbles, a larger or ſmaller quantity of loam, the loam more or leſs ſandy or clayey; and as to colour, it is the colour of the loam principally which conſtitutes the beauty of Gravel-walks, and that of a deepiſh yellow, or reddiſh colour is the moſt eligible, as when formed into walks well laid and rolled, is exceedingly beautiful and ornamental, and where ſuch Gravel can be procured within a moderate diſtance, and eaſy expence is preferable to all other; but in ſome parts, the Gravel is of an iron-mould colour, or of a duſky brown hue, which may nevertheleſs be of a proper quality for walks, provided the colour can be diſpenſed with, and as the moſt eſteemed high-coloured Gravel is not to be met with every where, we muſt be content with ſuch as nature affords.

It muſt however be remarked, that of whatever colour the Gravel, its proper quality for walks is, ſuch as has a due proportion of moderate loam, to make it bind cloſe and firm at all ſeaſons, but not ſo redundant in loam, nor ſo clayey as to be clammy and ſtick to the feet in wet weather, nor too ſharp and

ſandy,

ſandy, to become open and looſe in dry weather.

In ſome places, however, there is no other gravel but ſuch as is very looſe, ſandy, or pebbley, having ſcarcely any binding materials amongſt it, which kind of gravel will never of itſelf bind, but always remain open and looſe, and be at all times diſagreeable to walk on: this, therefore, ſhould be mended with a mixture of loam, where practicable, adding about one load to every two or three of gravel, caſting them together, and turning them over two or three times, that they may be well blended and incorporated; and this, when formed into a walk, will bind cloſe, firm, and ſmooth at all ſeaſons.

In preparing the gravel for your walks, it ſhould by no means be ſcreened, as is often the practice, only as it is dug out of the pit, caſt it up in a heap, or long ridge, and all ſuch large rough pebbles only as roll down, ſhould be cleared away; for if ſcreened from the ſtones, it will partake too much of the loam, as always to ſtick to the feet at every flaſh of rain, but by raking out juſt only the large rough ſtones, it will be ſufficiently fine, and the walk formed of ſuch will always be fit for uſe.

Gravel for walks, if it is to be purchaſed, is from about two to five or ſix ſhillings per cart-load for three horſes; though the price is different in different parts, and according to the nature of the Gravel; but about London, if they cart it home from the pits, it is commonly five or ſix ſhillings per load, or more according to the diſtance, and ſometimes they carry a load and a half at once, in the ſame cart, which is charged accordingly.

As to the diſtribution of Gravel walks in gardens, both for ornament and uſe, a magnificent walk of Gravel is neceſſary to proceed immediately parallel with the houſe, proportionable to its grandeur, extending each way in proportion to the width of the garden; and according to the former ſtyle of gardening, a large grand Gravel walk was uſually extended in a ſtreight line from the front of the habitation, along the middle of the pleaſure ground, ſometimes having graſs plats continued on each ſide, and ſometimes ſpacious borders furniſhed with curious ſhrubs and flowers; But in modern deſigns the above middle walk is rarely admitted, eſpecially in ſpacious gardens, having nothing in front beyond the parallel walk, but an open rural graſs lawn, free from all interſections of walks, &c. however, a grand walk cloſely parallel to the houſe, as obſerved above, is indiſpenſibly neceſſary, both for ornament and uſe; and from this, ſide walks ſhould branch off, communicating with the other parts of the garden, one in particular to be laid in a ſerpentine turn quite round the ground, others leading in the ſame manner through the interior parts, ſo as to have dry firm walking at all times to every part of the garden without walking upon the graſs, which ſometimes may be wet and diſagreeable.

As to the dimenſions for Gravel walks, they are to be regulated according to the extent of the garden, ſo may be from five to twenty feet or more wide, the length indeterminate; but all principal walks ſhould be at leaſt ten or twelve feet wide; and in large gardens, that leading directly from the houſe ſhould be fifteen or twenty feet wide at leaſt; tho' where the houſe and gardens are magnificent, the main walks contiguous to the manſion are ſometimes made thirty or forty feet wide; the boundaries on each ſide is ſometimes of graſs widely extended, and ſometimes are bounded by borders for flowers and other curious plants, having either narrow verges of graſs, or edgings of dwarf box, or thrift, &c. next the walk.

According, therefore, to the above rules, ſtake out the width of the walk, and proceed to form the boundary, each ſide of equal level, correſponding to the adjacent ground, and form the cavity of the walk for the reception of the gravel; obſerving that the whole ſpace muſt be digged at leaſt ten or twelve inches deep, to allow for a proper depth of gravel, both to prevent weeds riſing from the ground below, and worms from caſting up the earth therefrom; as alſo to allow for turning the gravel occaſionally when the ſurface becomes foul: the earth digged out to form the cavity of the walk, may be uſed to raiſe and form the ground on each ſide, if neceſſary, which, and the edgings, ſhould always be completed before you begin to lay the Gravel.

Every thing being ready for the reception of the Gravel, then you may in the firſt place lay any hard rubbiſhy materials in the bottom, ſeveral inches thick; ſuch as any coarſe gravel or ballaſt, or any rough ſtoney rubbiſh, which can be beſt procured, which will greatly prevent worm-caſts, and help to drain the moiſture from the top of the walk: the proper gravel is then to be laid ſix or eight inches thick at leaſt; as you proceed in laying, obſerve to raiſe the middle higher than the ſides,

in

in a gradually rounding form, which is not only neceſſary to throw off the wet, but alſo to give the walk a more ornamental appearance; the proportion to be obſerved in this is, that for a walk of five or ſix feet width, an inch and half riſe in the middle may be ſufficient; one of ten or twelve feet, two and a half; and one of twenty feet, four or five inches riſe will be enough; obſerving nearly the ſame proportion in any width whatſoever, and by no means raiſe the middle much higher, which would render the walk both uneaſy to walk upon, and of diſagreeable appearance; being particularly attentive to form the riſe all the way gradually rounding from both ſides to the middle, laying every part very exact and even; and at every ten or fifteen feet as you advance in laying, it is proper to tread, rake, and roll it, for gravel always rolls more firm and ſmooth whilſt it is freſh ſtirred; beſides, it is neceſſary for fear of rain happening; for which reaſons alſo, you ſhould never lay more in one day than you can finiſh off, except to rough lay it; the treading ſhould therefore be performed regularly with the feet pretty cloſe, taking ſhort ſteps; which work being neceſſary to render every part equally firm, and ſo as not to ſink in holes when you rake and roll it. The raking ſhould be performed lengthwiſe, and a rake without teeth is the moſt eligible, or, in default thereof, uſe the back of any common rake occaſionally, whereby you will be able to ſmooth the ſurface very evenly without drawing off the larger pebbles, or raking them into holes or heaps, as is unavoidable in uſing the teeth of a rake; for the art of ſmooth-raking is to leave all the top ſtones equally diſperſed over the ſurface. As ſoon as it is raked, let it be well rolled, both acroſs and lengthways,; and when the whole is laid, give a good rolling the whole length, repeating it till the ſurface is rendered perfectly compact, firm, and ſmooth; and if after the firſt ſhower of rain, you give it another good rolling, it will bind like a rock.

The management of Gravel walks, to keep them perfectly neat the year round, is occaſional weeding, ſweeping, and good rolling once or twice a week; and when the ſurface becomes very foul with weeds or moſs, as is often the caſe, the walk muſt be broken up in ſpring, and turned, the ſurface to the bottom, and the bottom to the top, whereby the weeds and moſs will not only be buried, but by turning up the freſh gravel, the walk will appear as freſh as when new laid. But the cuſtom of breaking up gravel walks in the beginning of winter, in rough ridges, to remain in that uſeleſs and unſightly manner till ſpring, to deſtroy weeds, &c. as is thought, is a very wrong practice, for the intention has rather the contrary effect; and the walks are thereby not only rendered uſeleſs for almoſt one half of the year, but at a time when there is hardly any dry or ſound walking upon graſs or other parts: beſides theſe inconveniencies, the walks appear not only unſightly in themſelves, but give alſo a very diſagreeable look to the adjacent parts of the garden: let the walks therefore always remain undiſturbed, at leaſt till ſpring, when, if neceſſary, they may be turned.

Rolling ſhould be performed once a week at leaſt, but if two or three times the more beautiful the walks will appear, and tend greatly to deſtroy weeds and moſs: it is, however, a general rule among gardeners, to ſweep and roll every Saturday; and during ſummer it is of much advantage to give a good rolling after rain, which will preſerve a compact ſmooth ſurface.

Turning gravel is a ſort of ſlight digging, turning the foul ſurface down and the freſh up, which being neceſſary, as above obſerved, when the ſurface is full of ſmall weeds, or very moſſy, and which is the only effectual method of deſtroying them; beſides, the work of turning is neceſſary once every year or two in ſpring, to turn up the freſh gravel to give the ſurface a lively appearance during ſummer; therefore ſome make it a rule to turn their principal Gravel walks every ſpring; and the proper time is April, when the weather is become ſettled and fine: in performing the work of turning, give every ſpit a clean turn, ſo as to turn the ſurface down, and the freſh gravel to the top; and as you go on, tread, rake, and roll, every ten or fifteen feet, as obſerved in new laying the walks.

GREEN-HOUSE, a garden-building fronted with glaſs, ſerving as a winter reſidence for tender plants from the warm parts of the world.

A very conſiderable ſhare of the vegetable creation that grow naturally in diſtant warm climates in open fields, &c. at all ſeaſons, which in their culture in this climate require protection in winter; obſerving, however, thoſe of the Green-houſe department being only from the warmer parts of the world, require

quire protection only from froſt, not needing aid of artificial heat, like ſtove-plants, from the hotteſt regions, except in very intenſe weather; when the aid of a moderate fire, burned either within the houſe, or in a furnace without, in the end or back wall, communicating the heat to flues or funnels ranging along the inſide. Though there may not be occaſion for any fire once in two or three years, yet it is adviſable in conſtructing a Green-houſe to erect flues to uſe occaſionally, which will prove ſerviceable, not only in ſevere froſts, but alſo in long moiſt foggy weather; a moderate fire now and then will dry up the damps, which would otherwiſe prove pernicious to ſeveral of the tender kinds of plants.

We will firſt exhibit a general ſketch of the dimenſions of a Green-houſe, then give a liſt of all the principal Green houſe plants uſually cultivated in the Engliſh gardens, together with their general culture.

A Green-houſe ſhould generally ſtand in the pleaſure-ground, and, if poſſible, upon a ſomewhat elevated and dry ſpot, full to the ſouth, and where the ſun has full acceſs from its riſing to ſetting; the building is commonly of brick or ſtone, having the front almoſt wholly of glaſs-work; and muſt range lengthways eaſt and weſt, with the front directly facing the ſouth, and ſhould generally be conſtructed upon an ornamental plan. As to its general dimenſions, with reſpect to length, width, and height, it may be from ten to fifty feet or more long, according to the number of plants you deſign it ſhall contain; and its width may be from ten or fifteen to twenty-four feet; though for a middling houſe fifteen or eighteen feet is a ſufficient width; and its height in the clear, ſhould be nearly in proportion to the width: but as to the erecting rooms over it, as is commonly directed, I ſhould adviſe to have none, as being not only an unneceſſary expence, but gives the building a heavy look, for all garden-buildings ſhould have a light airy appearance.

The walls in the back and ends ſhould be carried up two bricks, or about eighteen inches thick; though if the building is to be more than fifteen feet high, the walls ſhould be two bricks and a half thick; and at one end of the back wall, withoutſide, it is eligible to erect a furnace for burning fires occaſionally, as before obſerved, communicating with flues within, ranging in three or four returns along the back wall, alſo one flue running along the front and end walls, cloſe to or juſt under the floor; all of which will be extremely ſerviceable in time of intenſe froſts, and very damp foggy weather; and as to the front of the building, it ſhould have as much glaſs as poſſible, and a wide glaſs door ſhould be in the middle, both for ornament aud entrance, and for moving in and out the plants; and it would be convenient to have alſo a ſmaller private door at one end: the width of the windows for the glaſs ſaſhes, may be five or ſix feet, and the piers between the ſaſhes may be either of timber, ſix, eight, or ten inches wide, according to their height, or if of brick or ſtone work, muſt be two feet wide at leaſt, to be duly ſubſtantial, ſloping both ſides of each pier inward, that by taking off the angles, a freer admiſſion may be given to the rays of the ſun: for the ſame reaſon have the bottom of the ſaſhes to reach within a foot of the floor of the houſe, and their top reach almoſt as high as the cieling; and if brick or ſtone piers two feet wide, ſhutters may be hung withinſide to fall back againſt each pier: the roof may either be half glaſs-work, next the front; the other half ſlated, eſpecially if the upright or front piers are of timber; and ſhutters to cover the top glaſſes may be contrived to ſlide under the ſlated roof: but if the piers are of brick or ſtone, it is common to have the roof entirely either ſlated or tyled, but ſlating is the moſt ornamental, either for a half or whole roof; and the cieling within ſhould be lathed, and which, as well as the whole inſide-wall, ſhould be well plaiſtered and white-waſhed.

But in the modern conſtruction of Green-houſes, in order to have as much glaſs as poſſible in front, the piers between the ſaſhes are commonly of timber only, from ſix to eight or ten inches thick, according to the height, ſo as to admit as great a portion of light and heat of the ſun as may be; and on the ſame conſideration, continue glaſs-work ſloping half way up the roof, the other half ſlated, as above obſerved; and ſliding ſhutters alſo contrived to ſlide under the ſlated roof, to draw down occaſionally in ſevere weather, or in time of hail ſtorms, to defend the glaſſes; and for the front, may have either wooden or canvas ſhutters, or large canvas cloths upon rollers, to let down occaſionally, or, in default thereof, nail up garden-mats in ſevere weather.

Sometimes Green-houſes for large collections of plants, have two wings, of ſmaller dimenſions, added to the main building, one

at each end, in a right line, ſeparated ſometimes from it by a glaſs partition, with ſliding ſaſhes for communication, and the front almoſt wholly glaſs-work, and half glaſs roofs as above hinted; thus by theſe additional wings, the Green-houſe conſiſts of three diviſions, whereby the different qualities and temperatures of the various plants can be more eligibly ſuited. The middle or main diviſion may be for all the principal and more hardy, woody or ſhrubby kinds, which require protection only from froſt; one of the wings may be appropriated for the ſucculent tribe, and the other wing for the more tender kinds that require occaſional heat in winter, yet can live without the conſtant heat of a ſtove.

On whatever plan the Green houſe is conſtructed, let the whole inſide, both cieling and walls, be neatly finiſhed off with plaiſter and white-waſh, and all the wood-work painted white; and the bottom paved with large ſquare paving tyles.

The neceſſary utenſils of the Green houſe are principally ſome treſſels or ſtands for the ſupport of boards, on which to arrange the pots of plants, ſo as to have their heads range in a gradual ſlope from the back part to the front; but as ſome of the plants may be tall and in large tubs, and either do not require ſtands, or cannot be eaſily placed thereon, ſuch muſt be regulated as you ſhall ſee convenient.

From the above general ſketch, any one may form an idea of the principal dimenſions of a Green-houſe, which he may enlarge or diminiſh as it may ſuit his convenience.

*Green-houſe Plants.*

We will now proceed to exhibit, at one view, a liſt of the principal Green-houſe plants, having recourſe for particulars to each reſpective genus.

AGAVE, *Agave* or *American Aloe.*—Common great American Agave, with entire green leaves, and a branching flower ſtalk.—Common Agave, with ſtriped leaves.—Virginia Agave, with narrower pale green leaves. (*All ſucculent plants.*)

ALOE, *African Aloes.*—Mitre ſhaped Aloe.—Tree, or Sword Aloe.—Aloe Ferox.—Fan Aloe.—Succotorine Aloe.—Soap Aloe.—Partridge-breaſt Aloe.—Tongue Aloe.—Warted-tongue Aloe.—Pearl-tongue Aloe.—Cob-web Aloe.—Hedge-hog Aloe.—Cuſhion Aloe.—Spiral Aloe.—Pentangular Spiral Aloe.—Triangular Spiral Aloe.—*Iris Uvaria* Aloe; this Aloe will alſo live in a warm border.—(*All ſucculent.*)

ANDROMEDA, Tree Andromeda, or Carolina Sorrel-tree.——(*Shrubby.*)

ANTHERICUM, *Spider-wort.*——Shrubby, ſtalked, onion-leaved Anthericum—Aloe-leaved Anthericum—Mock-aſphodel Anthericum. (*Succulent.*)

ANTHOLYZA, *Æthiopian Corn-flag.*—Ringent Scarlet Antholyza—Æthiopian Crimſon Antholyza—Cunonia, or large-ſpathæed ſcarlet-flowered.——(*Herbaceous.*)

ANTHOSPERMUM, *Amber-tree.*—Æthiopium Smooth Amber-tree—— Ciliated Amber-tree.

ANTHYLLIS, Jupiter's Beard, or *Barba Jovis.*—Common *Barba Jovis*, or Silver Buſh—Spaniſh ternate-leaved *Barba Jovis*——Dwarf Portugal *Barba Jovis*—Erinacea, or Prickly *Anthyllis.* (*All of ſhrubby growth.*)

ANTIRRHINUM, Snap-dragon.—Variegated Snap-dragon—Gibraltar ſpotted-flowered *Linaria.* (Both of an herbaceous nature.)

ARCTOTIS, *Arctotis.*—Rough-leaved Arctotis.—Narrow-leaved Arctotis.—Sea Ragwort-leaved Arctotis.—Plantain-leaved Arctotis—Stalkleſs Arctotis; (are moſtly of a ſhrubby nature, except the laſt ſort.)

ARISTOLOCHIA, *Birth-wort.*—Evergreen Ariſtolochia——Piſtolochia, or ſmall Birthwort—Shrubby Birth-wort. (The two firſt are herbaceous, the other ſhrubby.)

ARTEMISIA, *Mug-wort.*—Tree Wormwood.

ASCLEPIAS, *Swallow-wort.*——Shrub Aſclepias.

ASPARAGUS. White Prickly Aſparagus.—Declinated Briſtly-leaved Aſparagus—Acute-leaved Aſparagus.—Retrofracted Great Prickly Aſparagus: have all ſomewhat ſhrubby ſtalks.

ASTER, *Star-wort.*——Shrubby African Aſters.

ASTRAGALUS, *Milk-vetch, &c.*——The *Tragacanth*, or Goats-thorn; ſeveral varieties. (*All ſhrubby.*)

ATROPA, *Deadly Night Shade.*—Shrubby Deadly Night Shade of Spain.

BACCHARIS, *Ploughman's Spikenard.*—Iva-leaved Baccharis—Oleander-leaved Baccharis—Halimus-leaved Baccharis. (*All ſhrubby.*)
